Update a DynamoDB table setting with warm throughput using an AWS SDK

The following code examples show how to update a table's warm throughput setting.

Java

SDK for Java 2.x

Update warm throughput setting on an existing DynamoDB table using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.GlobalSecondaryIndexUpdate;
import
 software.amazon.awssdk.services.dynamodb.model.UpdateGlobalSecondaryIndexAction;
import software.amazon.awssdk.services.dynamodb.model.UpdateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.WarmThroughput;

    public static WarmThroughput buildWarmThroughput(final Long
 readUnitsPerSecond, final Long writeUnitsPerSecond) {
        return WarmThroughput.builder()
            .readUnitsPerSecond(readUnitsPerSecond)
            .writeUnitsPerSecond(writeUnitsPerSecond)
            .build();
    }
```

```
   /**
    * Updates a DynamoDB table with warm throughput settings for both the table
and a global secondary index.
    *
    * @param ddb The DynamoDB client
    * @param tableName The name of the table to update
    * @param tableReadUnitsPerSecond Read units per second for the table

Update a DynamoDB item with a TTL using an AWS SDK

The following code examples show how to update an item's TTL.

Java

SDK for Java 2.x

Update TTL on an existing DynamoDB item in a table.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemRequest;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemResponse;

import java.util.HashMap;
import java.util.Map;
import java.util.Optional;

    public UpdateItemResponse updateItemWithTTL(
        final String tableName, final String primaryKeyValue, final String
 sortKeyValue) {
        // Get current time in epoch second format
        final long currentTime = System.currentTimeMillis() / 1000;

        // Calculate expiration time 90 days from now in epoch second format
        final long expireDate = currentTime + (DAYS_TO_EXPIRE * SECONDS_PER_DAY);

        // Create the key map for the item to update
        final Map<String, AttributeValue> keyMap = new HashMap<>();
        keyMap.put(PRIMARY_KEY_ATTR,
 AttributeValue.builder().s(primaryKeyValue).build());
        keyMap.put(SORT_KEY_ATTR,
 AttributeValue.builder().s(sortKeyValue).build());

        // Create the expression attribute values
        final Map<String, AttributeValue> expressionAttributeValues = new
 HashMap<>();
        expressionAttributeValues.put(
            ":c",
 AttributeValue.builder().n(String.valueOf(currentTime)).build());
        expressionAttributeValues.put(
            ":e",
 AttributeValue.builder().n(String.valueOf(expireDate)).build());
```

```
        final UpdateItemRequest request = UpdateItemRequest.builder()
            .tableName(tableName)
            .key(keyMap)
            .updateExpression(UPDATE_EXPRESSION)
            .expressionAttributeValues(expressionAttributeValues)
            .build();

        try {
            final UpdateItemResponse response =
 dynamoDbClient.updateItem(request);
            System.out.println(String.format(SUCCESS_MESSAGE, tableName));
            return response;
        } catch (ResourceNotFoundException e) {
            System.err.format(TABLE_NOT_FOUND_ERROR, tableName);
            throw e;
        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            throw e;
        }
    }
```

- For API details, see [UpdateItem](#) in *AWS SDK for Java 2.x API Reference*.

JavaScript

SDK for JavaScript (v3)

```
import { DynamoDBClient, UpdateItemCommand } from "@aws-sdk/client-dynamodb";
import { marshall, unmarshall } from "@aws-sdk/util-dynamodb";

export const updateItem = async (tableName, partitionKey, sortKey, region = 'us-
east-1') => {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const currentTime = Math.floor(Date.now() / 1000);
    const expireAt = Math.floor((Date.now() + 90 * 24 * 60 * 60 * 1000) / 1000);

    const params = {
        TableName: tableName,
```

```
        Key: marshall({
            partitionKey: partitionKey,
            sortKey: sortKey
        }),
        UpdateExpression: "SET updatedAt = :c, expireAt = :e",
        ExpressionAttributeValues: marshall({
            ":c": currentTime,
            ":e": expireAt
        }),
    };

    try {
        const data = await client.send(new UpdateItemCommand(params));
        const responseData = unmarshall(data.Attributes);
        console.log("Item updated successfully: %s", responseData);
        return responseData;
    } catch (err) {
        console.error("Error updating item:", err);
        throw err;
    }
}

// Example usage (commented out for testing)
// updateItem('your-table-name', 'your-partition-key-value', 'your-sort-key-
value');
```

- For API details, see UpdateItem in *AWS SDK for JavaScript API Reference*.

Python

SDK for Python (Boto3)

```
from datetime import datetime, timedelta

import boto3

def update_dynamodb_item(table_name, region, primary_key, sort_key):
    """
    Update an existing DynamoDB item with a TTL.
    :param table_name: Name of the DynamoDB table
```

```
    :param region: AWS Region of the table - example `us-east-1`
    :param primary_key: one attribute known as the partition key.
    :param sort_key: Also known as a range attribute.
    :return: Void (nothing)
    """
    try:
        # Create the DynamoDB resource.
        dynamodb = boto3.resource("dynamodb", region_name=region)
        table = dynamodb.Table(table_name)

        # Get the current time in epoch second format
        current_time = int(datetime.now().timestamp())

        # Calculate the expireAt time (90 days from now) in epoch second format
        expire_at = int((datetime.now() + timedelta(days=90)).timestamp())

        table.update_item(
            Key={"partitionKey": primary_key, "sortKey": sort_key},
            UpdateExpression="set updatedAt=:c, expireAt=:e",
            ExpressionAttributeValues={":c": current_time, ":e": expire_at},
        )

        print("Item updated successfully.")
    except Exception as e:
        print(f"Error updating item: {e}")

# Replace with your own values
update_dynamodb_item(
    "your-table-name", "us-west-2", "your-partition-key-value", "your-sort-key-
value"
)
```

Use API Gateway to invoke a Lambda function

The following code examples show how to create an AWS Lambda function invoked by Amazon API Gateway.

Java

SDK for Java 2.x

Shows how to create an AWS Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans

an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to create an AWS Lambda function by using the Lambda JavaScript runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

This example is also available in the AWS SDK for JavaScript v3 developer guide.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

Python

SDK for Python (Boto3)

This example shows how to create and use an Amazon API Gateway REST API that targets an AWS Lambda function. The Lambda handler demonstrates how to route based on HTTP methods; how to get data from the query string, header, and body; and how to return a JSON response.

- Deploy a Lambda function.
- Create an API Gateway REST API.
- Create a REST resource that targets the Lambda function.
- Grant permission to let API Gateway invoke the Lambda function.
- Use the Requests package to send requests to the REST API.
- Clean up all resources created during the demo.

This example is best viewed on GitHub. For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use Step Functions to invoke Lambda functions

The following code example shows how to create an AWS Step Functions state machine that invokes AWS Lambda functions in sequence.

Java

SDK for Java 2.x

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for Java 2.x. Each workflow step is implemented using an AWS Lambda function.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use a document model for DynamoDB using an AWS SDK

The following code example shows how to perform Create, Read, Update, and Delete (CRUD) and batch operations using a document model for DynamoDB and an AWS SDK.

For more information, see Document model.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Perform CRUD operations using a document model.

```
    /// <summary>
    /// Performs CRUD operations on an Amazon DynamoDB table.
    /// </summary>
    public class MidlevelItemCRUD
    {
        public static async Task Main()

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use a high-level object persistence model for DynamoDB using an AWS SDK

The following code example shows how to perform Create, Read, Update, and Delete (CRUD) and batch operations using an object persistence model for DynamoDB and an AWS SDK.

For more information, see Object persistence model.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Perform CRUD operations using a high-level object persistence model.

```
    /// <summary>
    /// Shows how to perform high-level CRUD operations on an Amazon DynamoDB
    /// table.
    /// </summary>
    public class HighLevelItemCrud
    {
        public static async Task Main()
        {
            var client = new AmazonDynamoDBClient();

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use atomic counter operations in DynamoDB with an AWS SDK

The following code examples show how to use atomic counter operations in DynamoDB.

- Increment counters atomically using ADD and SET operations.
- Safely increment counters that might not exist.
- Implement optimistic locking for counter operations.

Java

SDK for Java 2.x

Demonstrate atomic counter operations using AWS SDK for Java 2.x.

Python

SDK for Python (Boto3)

Demonstrate atomic counter operations using AWS SDK for Python (Boto3).

```
import boto3
from botocore.exceptions import ClientError
from typing import Any, Dict, Union

def increment_counter_with_add(
    table_name: str, key: Dict[str, Any], counter_name: str, increment_value: int
 = 1
) -> Dict[str, Any]:
    """
    Increment a counter attribute using the ADD operation.

    This function demonstrates the atomic ADD operation, which is ideal for
    incrementing counters without the risk of race conditions.

    Args:
        table_name (str): The name of the DynamoDB table.
        key (Dict[str, Any]): The primary key of the item to update.
        counter_name (str): The name of the counter attribute.
        increment_value (int, optional): The value to increment by. Defaults to
 1.

    Returns:
```

```
        Dict[str, Any]: The response from DynamoDB containing the updated
 attribute values.
    """
    # Initialize the DynamoDB resource
    dynamodb = boto3.resource("dynamodb")
    table = dynamodb.Table(table_name)

    # Use the ADD operation to atomically increment the counter
    response = table.update_item(
        Key=key,
        UpdateExpression="ADD #counter :increment",
        ExpressionAttributeNames={"#counter": counter_name},
        ExpressionAttributeValues={":increment": increment_value},
        ReturnValues="UPDATED_NEW",

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use conditional operations in DynamoDB with an AWS SDK

The following code examples show how to use conditional operations in DynamoDB.

- Implement conditional writes to prevent overwriting data.
- Use condition expressions to enforce business rules.
- Handle conditional check failures gracefully.

Java

SDK for Java 2.x

Demonstrate conditional operations using AWS SDK for Java 2.x.

```

Use expression attribute names in DynamoDB with an AWS SDK

The following code examples show how to use expression attribute names in DynamoDB.

- Work with reserved words in DynamoDB expressions.
- Use expression attribute name placeholders.

- Handle special characters in attribute names.

Java

SDK for Java 2.x

Demonstrate expression attribute names using AWS SDK for Java 2.x.

Use scheduled events to invoke a Lambda function

The following code examples show how to create an AWS Lambda function invoked by an Amazon EventBridge scheduled event.

Java

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda JavaScript runtime API. This example invokes different AWS services to perform a specific

use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

This example is also available in the AWS SDK for JavaScript v3 developer guide.

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

Python

SDK for Python (Boto3)

This example shows how to register an AWS Lambda function as the target of a scheduled Amazon EventBridge event. The Lambda handler writes a friendly message and the full event data to Amazon CloudWatch Logs for later retrieval.

- Deploys a Lambda function.
- Creates an EventBridge scheduled event and makes the Lambda function the target.
- Grants permission to let EventBridge invoke the Lambda function.
- Prints the latest data from CloudWatch Logs to show the result of the scheduled invocations.
- Cleans up all resources created during the demo.

This example is best viewed on GitHub. For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch Logs
- DynamoDB

- EventBridge
- Lambda
- Amazon SNS

Work with DynamoDB Local Secondary Indexes using AWS Command Line Interface v2

The following code example shows how to create and query tables with Local Secondary Indexes.

- Create a table with a Local Secondary Index (LSI).
- Create a table with multiple LSIs with different projection types.
- Query data using LSIs.

Bash

AWS CLI with Bash script

Create a table with a Local Secondary Index.

```
# Create a table with a Local Secondary Index
aws dynamodb create-table \
    --table-name CustomerOrders \
    --attribute-definitions \
        AttributeName=CustomerID,AttributeType=S \
        AttributeName=OrderID,AttributeType=S \
        AttributeName=OrderDate,AttributeType=S \
    --key-schema \
        AttributeName=CustomerID,KeyType=HASH \
        AttributeName=OrderID,KeyType=RANGE \
    --local-secondary-indexes \
        "IndexName=OrderDateIndex,\
        KeySchema=[{AttributeName=CustomerID,KeyType=HASH},
{AttributeName=OrderDate,KeyType=RANGE}],\
        Projection={ProjectionType=ALL}" \
    --billing-mode PAY_PER_REQUEST
```

Create a table with multiple LSIs.

```
# Create a table with multiple Local Secondary Indexes
aws dynamodb create-table \
    --table-name CustomerDetails \
    --attribute-definitions \
        AttributeName=CustomerID,AttributeType=S \
        AttributeName=Name,AttributeType=S \
        AttributeName=Email,AttributeType=S \
        AttributeName=RegistrationDate,AttributeType=S \
    --key-schema \
        AttributeName=CustomerID,KeyType=HASH \
        AttributeName=Name,KeyType=RANGE \
    --local-secondary-indexes \
        "[
            {
                \"IndexName\": \"EmailIndex\",
                \"KeySchema\": [
                    {\"AttributeName\":\"CustomerID\",\"KeyType\":\"HASH\"},
                    {\"AttributeName\":\"Email\",\"KeyType\":\"RANGE\"}
                ],
                \"Projection\": {\"ProjectionType\":\"INCLUDE\",
\"NonKeyAttributes\":[\"Address\",\"Phone\"]}
            },
            {
                \"IndexName\": \"RegistrationIndex\",
                \"KeySchema\": [
                    {\"AttributeName\":\"CustomerID\",\"KeyType\":\"HASH\"},
                    {\"AttributeName\":\"RegistrationDate\",\"KeyType\":\"RANGE
\"}
                ],
                \"Projection\": {\"ProjectionType\":\"KEYS_ONLY\"}
            }
        ]" \
    --billing-mode PAY_PER_REQUEST
```

Query data using LSIs.

```
# Query the OrderDateIndex LSI
aws dynamodb query \
```

```
    --table-name CustomerOrders \
    --index-name OrderDateIndex \
    --key-condition-expression "CustomerID = :custId AND OrderDate BETWEEN :date1
 AND :date2" \
    --expression-attribute-values '{
        ":custId": {"S": "C1"},
        ":date1": {"S": "2023-01-01"},
        ":date2": {"S": "2023-02-01"}
    }'

# Query with a filter expression
aws dynamodb query \
    --table-name CustomerOrders \
    --index-name OrderDateIndex \
    --key-condition-expression "CustomerID = :custId" \
    --filter-expression "Amount > :amount" \
    --expression-attribute-values '{
        ":custId": {"S": "C1"},
        ":amount": {"N": "150"}
    }'
```

Work with DynamoDB Streams and Time-to-Live using AWS Command Line Interface v2

The following code example shows how to manage DynamoDB Streams and Time-to-Live features.

- Create a table with Streams enabled.
- Describe Streams.
- Create a Lambda function for processing Streams.
- Enable TTL on a table.

- Add items with TTL attributes.
- Describe TTL settings.

Bash

AWS CLI with Bash script

Create a table with Streams enabled.

```
# Create a table with DynamoDB Streams enabled
aws dynamodb create-table \
    --table-name StreamsDemo \
    --attribute-definitions \
        AttributeName=ID,AttributeType=S \
    --key-schema \
        AttributeName=ID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES
```

Describe Streams.

```
# Get information about the stream
aws dynamodb describe-table \
    --table-name StreamsDemo \
    --query "Table.StreamSpecification"

# Get the stream ARN
STREAM_ARN=$(aws dynamodb describe-table \
    --table-name StreamsDemo \
    --query "Table.LatestStreamArn" \
    --output text)

echo "Stream ARN: $STREAM_ARN"

# Describe the stream
aws dynamodbstreams describe-stream \
    --stream-arn $STREAM_ARN
```

Create a Lambda function for Streams.

```
# Step 1: Create an IAM role for the Lambda function
cat > trust-policy.json << 'EOF'
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
EOF

aws iam create-role \
    --role-name DynamoDBStreamsLambdaRole \
    --assume-role-policy-document file://trust-policy.json

# Step 2: Attach permissions to the role
aws iam attach-role-policy \
    --role-name DynamoDBStreamsLambdaRole \
    --policy-arn arn:aws:iam::aws:policy/service-role/
AWSLambdaDynamoDBExecutionRole

# Step 3: Create a Lambda function (code would be in a separate file)
echo "Lambda function creation would be done separately with appropriate code"

# Step 4: Create an event source mapping
echo "Example command to create event source mapping:"
echo "aws lambda create-event-source-mapping \\"
echo "    --function-name ProcessDynamoDBRecords \\"
echo "    --event-source $STREAM_ARN \\"
echo "    --batch-size 100 \\"
echo "    --starting-position LATEST"
```

Enable TTL on a table.

```
# Create a table for TTL demonstration
aws dynamodb create-table \
    --table-name TTLDemo \
```

```
    --attribute-definitions \
        AttributeName=ID,AttributeType=S \
    --key-schema \
        AttributeName=ID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST

# Wait for table to become active
aws dynamodb wait table-exists --table-name TTLDemo

# Enable TTL on the table
aws dynamodb update-time-to-live \
    --table-name TTLDemo \
    --time-to-live-specification "Enabled=true, AttributeName=ExpirationTime"
```

Add items with TTL attributes.

```
# Calculate expiration time (current time + 1 day in seconds)
EXPIRATION_TIME=$(date -d "+1 day" +%s)

# Add an item with TTL attribute
aws dynamodb put-item \
    --table-name TTLDemo \
    --item '{
        "ID": {"S": "item1"},
        "Data": {"S": "This item will expire in 1 day"},
        "ExpirationTime": {"N": "'$EXPIRATION_TIME'"}
    }'

# Add an item that expires in 1 hour
EXPIRATION_TIME_HOUR=$(date -d "+1 hour" +%s)
aws dynamodb put-item \
    --table-name TTLDemo \
    --item '{
        "ID": {"S": "item2"},
        "Data": {"S": "This item will expire in 1 hour"},
        "ExpirationTime": {"N": "'$EXPIRATION_TIME_HOUR'"}
    }'
```

Describe TTL settings.

```
# Describe TTL settings for a table
```

```
aws dynamodb describe-time-to-live \
    --table-name TTLDemo
```

Work with DynamoDB global tables and multi-Region replication with eventual consistency (MREC) using AWS Command Line Interface v2

The following code example shows how to manage DynamoDB global tables with multi-Region replication with eventual consistency (MREC).

- Create a table with multi-Region replication (MREC).
- Put and get items from replica tables.
- Remove replicas one-by-one.
- Clean up by deleting the table.

Bash

AWS CLI with Bash script

Create a table with multi-Region replication.

```
# Step 1: Create a new table (MusicTable) in US East (Ohio), with DynamoDB
 Streams enabled (NEW_AND_OLD_IMAGES)
```

```
aws dynamodb create-table \
    --table-name MusicTable \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
    --region us-east-2

# Step 2: Create an identical MusicTable table in US East (N. Virginia)
aws dynamodb update-table --table-name MusicTable --cli-input-json \
'{
  "ReplicaUpdates":
  [
    {
      "Create": {
        "RegionName": "us-east-1"
      }
    }
  ]
}' \
--region us-east-2

# Step 3: Create a table in Europe (Ireland)
aws dynamodb update-table --table-name MusicTable --cli-input-json \
'{
  "ReplicaUpdates":
  [
    {
      "Create": {
        "RegionName": "eu-west-1"
      }
    }
  ]
}' \
--region us-east-2
```

Describe the multi-Region table.

```
# Step 4: View the list of replicas created using describe-table
aws dynamodb describe-table \
    --table-name MusicTable \
    --region us-east-2 \
    --query 'Table.
{TableName:TableName,TableStatus:TableStatus,MultiRegionConsistency:MultiRegionConsistenc
{Region:RegionName,Status:ReplicaStatus}}'
```

Put items in a replica table.

```
# Step 5: To verify that replication is working, add a new item to the Music
 table in US East (Ohio)
aws dynamodb put-item \
    --table-name MusicTable \
    --item '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region us-east-2
```

Get items from replica tables.

```
# Step 6: Wait for a few seconds, and then check to see whether the item has
 been
# successfully replicated to US East (N. Virginia) and Europe (Ireland)
aws dynamodb get-item \
    --table-name MusicTable \
    --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region us-east-1

aws dynamodb get-item \
    --table-name MusicTable \
    --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region eu-west-1
```

Remove replicas.

```
# Step 7: Delete the replica table in Europe (Ireland) Region
aws dynamodb update-table --table-name MusicTable --cli-input-json \
'{
  "ReplicaUpdates":
```

```
  [
    {
      "Delete": {
        "RegionName": "eu-west-1"
      }
    }
  ]
}' \
--region us-east-2

# Delete the replica table in US East (N. Virginia) Region
aws dynamodb update-table --table-name MusicTable --cli-input-json \
'{
  "ReplicaUpdates":
  [
    {
      "Delete": {
        "RegionName": "us-east-1"
      }
    }
  ]
}' \
--region us-east-2
```

Clean up by deleting the table.

```
# Clean up: Delete the primary table
aws dynamodb delete-table --table-name MusicTable --region us-east-2

echo "Global table demonstration complete."
```

- For API details, see the following topics in *AWS CLI Command Reference*.
  - CreateTable
  - DeleteTable
  - DescribeTable
  - GetItem

Work with DynamoDB resource tagging using AWS Command Line Interface v2

The following code example shows how to manage tags for DynamoDB resources.

- Create a table with tags.
- List tags for a resource.
- Add tags to a resource.
- Remove tags from a resource.
- Filter tables by tags.

Bash

AWS CLI with Bash script

Create a table with tags.

```
# Create a table with tags
aws dynamodb create-table \
    --table-name TaggedTable \
    --attribute-definitions \
        AttributeName=ID,AttributeType=S \
    --key-schema \
        AttributeName=ID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --tags \
        Key=Environment,Value=Production \
        Key=Project,Value=Analytics \
        Key=Owner,Value=DataTeam
```

List tags for a resource.

```
# Get the table ARN
```

```
TABLE_ARN=$(aws dynamodb describe-table \
    --table-name TaggedTable \
    --query "Table.TableArn" \
    --output text)

# List tags for the table
aws dynamodb list-tags-of-resource \
    --resource-arn $TABLE_ARN
```

Add tags to a resource.

```
# Add tags to an existing table
aws dynamodb tag-resource \
    --resource-arn $TABLE_ARN \
    --tags \
        Key=CostCenter,Value=12345 \
        Key=BackupSchedule,Value=Daily
```

Remove tags from a resource.

```
# Remove tags from a table
aws dynamodb untag-resource \
    --resource-arn $TABLE_ARN \
    --tag-keys Owner BackupSchedule
```

Filter tables by tags.

```
# Create another table with different tags
aws dynamodb create-table \
    --table-name AnotherTaggedTable \
    --attribute-definitions \
        AttributeName=ID,AttributeType=S \
    --key-schema \
        AttributeName=ID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --tags \
        Key=Environment,Value=Development \
        Key=Project,Value=Testing
```

```
# Wait for table to become active
aws dynamodb wait table-exists --table-name AnotherTaggedTable

# List all tables
echo "All tables:"
aws dynamodb list-tables

# Get ARNs for all tables
echo -e "\nFiltering tables by Environment=Production tag:"
TABLE_ARNS=$(aws dynamodb list-tables --query "TableNames[*]" --output text |
 xargs -I {} aws dynamodb describe-table --table-name {} --query "Table.TableArn"
 --output text)

# Find tables with specific tag
for ARN in $TABLE_ARNS; do
    TABLE_NAME=$(echo $ARN | awk -F/ '{print $2}')
    TAGS=$(aws dynamodb list-tags-of-resource --resource-arn $ARN --query "Tags[?
Key=='Environment' && Value=='Production']" --output text)
    if [ ! -z "$TAGS" ]; then
        echo "Table with Production tag: $TABLE_NAME"
    fi
done
```

Work with DynamoDB table encryption using AWS Command Line Interface v2

The following code example shows how to manage encryption options for DynamoDB tables.

- Create a table with default encryption.

- Create a table with a customer managed CMK.
- Update table encryption settings.
- Describe table encryption.

Bash

AWS CLI with Bash script

Create a table with default encryption.

```
# Create a table with default encryption (AWS owned key)
aws dynamodb create-table \
    --table-name CustomerData \
    --attribute-definitions \
        AttributeName=CustomerID,AttributeType=S \
    --key-schema \
        AttributeName=CustomerID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --sse-specification Enabled=true,SSEType=KMS
```

Create a table with a customer managed CMK.

```
# Step 1: Create a customer managed key in KMS
aws kms create-key \
    --description "Key for DynamoDB table encryption" \
    --key-usage ENCRYPT_DECRYPT \
    --customer-master-key-spec SYMMETRIC_DEFAULT

# Store the key ID for later use
KEY_ID=$(aws kms list-keys --query "Keys[?contains(KeyArn, 'Key for
 DynamoDB')].KeyId" --output text)

# Step 2: Create a table with the customer managed key
aws dynamodb create-table \
    --table-name SensitiveData \
    --attribute-definitions \
        AttributeName=RecordID,AttributeType=S \
    --key-schema \
        AttributeName=RecordID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
```

```
    --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=$KEY_ID
```

Update table encryption.

```
# Update a table to use a different KMS key
aws dynamodb update-table \
    --table-name CustomerData \
    --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=$KEY_ID
```

Describe table encryption.

```
# Describe the table to see encryption settings
aws dynamodb describe-table \
    --table-name CustomerData \
    --query "Table.SSEDescription"
```

- For API details, see the following topics in *AWS CLI Command Reference*.
  - CreateKey
  - CreateTable
  - DescribeTable
  - UpdateTable

Serverless examples for DynamoDB

The following code examples show how to use DynamoDB with AWS SDKs.

Examples

- Invoke a Lambda function from a DynamoDB trigger
- Reporting batch item failures for Lambda functions with a DynamoDB trigger

Invoke a Lambda function from a DynamoDB trigger

The following code examples show how to implement a Lambda function that receives an event triggered by receiving records from a DynamoDB stream. The function retrieves the DynamoDB payload and logs the record contents.

.NET

AWS community contributions for DynamoDB

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

Examples

- Build and test a serverless application

Build and test a serverless application

The following code examples show how to build and test a serverless application using API Gateway with Lambda and DynamoDB

.NET

SDK for .NET

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the .NET SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda

Go

SDK for Go V2

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Go SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda

Java

SDK for Java 2.x

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Java SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda

Rust

SDK for Rust

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Rust SDK.

Security and compliance in Amazon DynamoDB

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the AWS compliance programs. To learn about the compliance programs that apply to DynamoDB, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation will help you understand how to apply the shared responsibility model when using DynamoDB. The following topics show you how to configure DynamoDB to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you to monitor and secure your DynamoDB resources.

AWS managed policies for Amazon DynamoDB

DynamoDB uses AWS managed policies to define a set of permissions the service needs to perform specific actions. DynamoDB maintains and updates its AWS managed policies. You can't change the permissions in AWS managed policies. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

DynamoDB might occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. An AWS managed policy is most likely to be updated when a new feature is launched or when new operations become available. DynamoDB will not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions. For a full list of AWS managed policies, see AWS managed policies.

AWS managed policy: DynamoDBReplicationServiceRolePolicy

You can’t attach the `DynamoDBReplicationServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows DynamoDB to perform actions on your behalf. For more information, see Using IAM with global tables.

This policy grants permissions that allow the service-linked role to perform data replication between global table replicas. It also grants administrative permissions to manage global table replicas on your behalf.

Permissions details

This policy grants permissions to do the following:

- `dynamodb` – Perform data replication and manage table replicas.
- `application-autoscaling` – Retrieve and manage table Auto Scaling settings
- `account` – Retrieve region status for evaluating replica accessibility.
- `iam` – To create the service-linked role for application Auto Scaling in the event that the service-linked role does not already exist.

For more information, see DynamoDBReplicationServiceRolePolicy in the AWS Managed Policy Reference.

AWS managed policy: AmazonDynamoDBFullAccess_v2

The scoped-down AmazonDynamoDBFullAccess_v2 policy grants specific access privileges to users. You can attach the AmazonDynamoDBFullAccess_v2 policy to your IAM identities. This policy grants administrative access to Amazon DynamoDB resources and grants an IAM identity (such as a user, group, or role) access to the AWS services that DynamoDB is integrated with to use all of DynamoDB features. Using this policy allows access to all of DynamoDB features that are available in the AWS Management Console.

Permissions details

This policy includes the following permissions:

- Amazon DynamoDB
- DynamoDB Accelerator
- AWS KMS
- AWS Resource Groups Tagging
- Lambda
- Application Auto Scaling
- CloudWatch
- Amazon Kinesis
- Amazon EC2
- IAM

To review the policy in JSON format, see AmazonDynamoDBFullAccess_v2.

AWS managed policy: AmazonDynamoDBReadOnlyAccess

You can attach the AmazonDynamoDBReadOnlyAccess policy to your IAM identities.

This policy grants read-only access to Amazon DynamoDB.

Permissions details

This policy includes the following permissions:

- `Amazon DynamoDB` – Provides read-only access to Amazon DynamoDB.
- `Amazon DynamoDB Accelerator (DAX)` – Provides read-only access to Amazon DynamoDB Accelerator (DAX).
- `Application Auto Scaling` – Allows principals to view configurations from Application Auto Scaling. This is required so that users can view automatic scaling policies that are attached to a table.
- `CloudWatch` – Allows principals to view metric data and alarms configured in CloudWatch. This is required so users can view the billable table size and CloudWatch alarms that have been configured for a table.
- `AWS Data Pipeline` – Allows principals to view AWS Data Pipeline and associated objects.
- `Amazon EC2` – Allows principals to view Amazon EC2 VPCs, subnets, and security groups.
- `IAM` – Allows principals to view IAM roles.
- `AWS KMS` – Allows principals to view keys configured in AWS KMS. This is required so users can view AWS KMS keys that they create and manage in their account.
- `Amazon SNS` – Allows principals to list Amazon SNS topics and subscriptions by topic.
- `AWS Resource Groups` – Allows principals to view resource groups and their queries.
- `AWS Resource Groups Tagging` – Allows principals to list all the tagged or previously tagged resources in a Region.
- `Kinesis` – Allows principals to view Kinesis data streams descriptions.
- `Amazon CloudWatch Contributor Insights` – Allow principals to view time series data collected by Contributor Insights rules.

To review the policy in `JSON` format, see AmazonDynamoDBReadOnlyAccess.

DynamoDB updates to AWS managed policies

This table shows updates to the AWS access management policies for DynamoDB.

Change	Description	Date Changed
`AmazonDynamoDBFullAccess` – Deprecated	This policy has been replaced by a scoped-down policy named `AmazonDynamoDBFullAccess_v2` .	April 28, 2025

Change	Description	Date Changed
	The AmazonDynamoDBFullAccess policy is deprecated and is no longer recommended.	
AmazonDynamoDBReadOnlyAccess update to an existing policy	AmazonDynamoDBReadOnlyAccess added the permissions: dynamodb:GetAbacStatus and dynamodb:UpdateAbacStatus. These permissions allow you to view the ABAC status and enable ABAC for your AWS account in the current Region.	November 18, 2024
AmazonDynamoDBReadOnlyAccess update to an existing policy	AmazonDynamoDBReadOnlyAccess added the permission dynamodb:GetResourcePolicy. This permission provides access to read resource-based policies attached to DynamoDB resources.	March 20, 2024
DynamoDBReplicationServiceRolePolicy update to an existing policy	DynamoDBReplicationServiceRolePolicy added the permission dynamodb:GetResourcePolicy. This permission allows the service-linked role to read resource-based policies attached to DynamoDB resources.	December 15, 2023
DynamoDBReplicationServiceRolePolicy update to an existing policy	DynamoDBReplicationServiceRolePolicy added the permission account:ListRegions. This permission allows the service-linked role to evaluate replica accessibility	May 10, 2023

Change	Description	Date Changed
DynamoDBR eplicatio nServiceR olePolicy added to list of managed policies	Added information about the managed policy DynamoDBR eplicationServiceR olePolicy , which is used by the DynamoDB global tables service-l inked role.	May 10, 2023
DynamoDB global tables started tracking changes	DynamoDB global tables started tracking changes for its AWS managed policies.	May 10, 2023

Using resource-based policies for DynamoDB

DynamoDB supports resource-based policies for tables, indexes, and streams. Resource-based policies let you define access permissions by specifying who has access to each resource, and the actions they are allowed to perform on each resource.

You can attach a resource-based policy to DynamoDB resources, such as a table or a stream. In this policy, you specify permissions for Identity and Access Management (IAM) principals that can perform specific actions on these DynamoDB resources. For example, the policy attached to a table will contain permissions for access to the table and its indexes. As a result, resource-based policies can help you simplify access control for your DynamoDB tables, indexes, and streams, by defining permissions at the resource level. The maximum size of a policy you can attach to a DynamoDB resource is 20 KB.

A significant benefit of using resource-based policies is to simplify cross-account access control for providing cross-account access to IAM principals in different AWS accounts. For more information, see Resource-based policy for cross-account access.

Resource-based policies also support integrations with IAM Access Analyzer external access analyzer and Block Public Access (BPA) capabilities. IAM Access Analyzer reports cross-account access to external entities specified in resource-based policies. It also provides visibility to help you refine permissions and conform to the least privilege principle. BPA helps you prevent public access

to your DynamoDB tables, indexes, and streams, and is automatically enabled in the resource-based policies creation and modification workflows.

Topics

- Create a table with a resource-based policy
- Attach a policy to an DynamoDB existing table
- Attach a resource-based policy to a DynamoDB stream
- Remove a resource-based policy from a DynamoDB table
- Cross-account access with resource-based policies in DynamoDB
- Blocking public access with resource-based policies in DynamoDB
- DynamoDB API operations supported by resource-based policies
- Authorization with IAM identity-based policies and DynamoDB resource-based policies
- DynamoDB resource-based policy examples
- DynamoDB resource-based policy considerations
- DynamoDB resource-based policy best practices

Create a table with a resource-based policy

You can add a resource-based policy while you create a table by using the DynamoDB console, CreateTable API, AWS CLI, AWS SDK, or an CloudFormation template.

AWS CLI

The following example creates a table named *MusicCollection* using the `create-table` AWS CLI command. This command also includes the `resource-policy` parameter that adds a resource-based policy to the table. This policy allows the user *John* to perform the RestoreTableToPointInTime, GetItem, and PutItem API actions on the table.

Remember to replace the *italicized* text with your resource-specific information.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S
 AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH
 AttributeName=SongTitle,KeyType=RANGE \
```

```
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --resource-policy \
        "{
            \"Version\": \"2012-10-17\",
            \"Statement\": [
              {
                    \"Effect\": \"Allow\",
                    \"Principal\": {
                        \"AWS\": \"arn:aws:iam::123456789012:user/John\"
                    },
                    \"Action\": [
                        \"dynamodb:RestoreTableToPointInTime\",
                        \"dynamodb:GetItem\",
                        \"dynamodb:DescribeTable\"
                    ],
                    \"Resource\": \"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection\"
                }
            ]
        }"
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. On the dashboard, choose **Create table**.
3. In **Table details**, enter the table name, partition key, and sort key details.
4. In **Table settings**, choose **Customize settings**.
5. (Optional) Specify your options for **Table class**, **Capacity calculator**, **Read/write capacity settings**, **Secondary indexes**, **Encryption at rest**, and **Deletion protection**.
6. In **Resource-based policy**, add a policy to define the access permissions for the table and its indexes. In this policy, you specify who has access to these resources, and the actions they are allowed to perform on each resource. To add a policy, do one of the following:

   - Type or paste a JSON policy document. For details about the IAM policy language, see Creating policies using the JSON editor in the *IAM User Guide*.

> **Tip**
>
> To see examples of resource-based policies in the Amazon DynamoDB Developer Guide, choose **Policy examples**.

- Choose **Add new statement** to add a new statement and enter the information in the provided fields. Repeat this step for as many statements as you would like to add.

> **Important**
>
> Make sure that you resolve any security warnings, errors, or suggestions before you save your policy.

The following IAM policy example allows the user *John* to perform the RestoreTableToPointInTime, GetItem, and PutItem API actions on the table *MusicCollection*.

Remember to replace the *italicized* text with your resource-specific information.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/username"
      },
      "Action": [
        "dynamodb:RestoreTableToPointInTime",
        "dynamodb:GetItem",
        "dynamodb:PutItem"
      ],
      "Resource": "arn:aws:dynamodb:us-
east-1:123456789012:table/MusicCollection"
    }
```

```
  ]
}
```

7. (Optional) Choose **Preview external access** in the lower-right corner to preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to create an account analyzer in IAM Access Analyzer. For more information, see Preview access.
8. Choose **Create table**.

AWS CloudFormation template

Using the AWS::DynamoDB::Table resource

The following CloudFormation template creates a table with a stream using the AWS::DynamoDB::Table resource. This template also includes resource-based policies that are attached to both the table and the stream.

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "MusicCollectionTable": {
            "Type": "AWS::DynamoDB::Table",
            "Properties": {
                "AttributeDefinitions": [
                    {

          }

      }
  }
```

```
}
```

Using the AWS::DynamoDB::GlobalTable resource

The following CloudFormation template creates a table with the AWS::DynamoDB::GlobalTable resource and attaches a resource-based policy to the table and its stream.

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "GlobalMusicCollection": {
            "Type": "AWS::DynamoDB::GlobalTable",
            "Properties": {
                "TableName": "MusicCollection",
                "AttributeDefinitions": [{
                    "AttributeName": "Artist",
                    "AttributeType": "S"
                }],
                "KeySchema": [{
                    "AttributeName": "Artist",
                    "KeyType": "HASH"
                }],
                "BillingMode": "PAY_PER_REQUEST",
                "StreamSpecification": {
                    "StreamViewType": "NEW_AND_OLD_IMAGES"
                },
                "Replicas": [
                    {
                        "Region": "us-east-1",
                        "ResourcePolicy": {
                            "PolicyDocument": {
                                "Version": "2012-10-17",
                                "Statement": [{
                                    "Principal": {
                                        "AWS": [
                                            "arn:aws:iam::111122223333:user/John"
                                        ]
                                    },
                                    "Effect": "Allow",
                                    "Action": "dynamodb:GetItem",
                                    "Resource": "*"
                                }]
                            }
```

```
                        },
                        "ReplicaStreamSpecification": {
                            "ResourcePolicy": {
                                "PolicyDocument": {
                                    "Version": "2012-10-17",
                                    "Statement": [{
                                        "Principal": {
                                            "AWS":
 "arn:aws:iam::111122223333:user/John"
                                        },
                                        "Effect": "Allow",
                                        "Action": [
                                            "dynamodb:GetRecords",
                                            "dynamodb:GetShardIterator",
                                            "dynamodb:DescribeStream"
                                        ],
                                        "Resource": "*"
                                    }]
                                }
                            }
                        }
                    }
                ]
            }
        }
    }
}
```

Attach a policy to an DynamoDB existing table

You can attach a resource-based policy to an existing table or modify an existing policy by using the DynamoDB console, PutResourcePolicy API, the AWS CLI, AWS SDK, or an CloudFormation template.

AWS CLI example to attach a new policy

The following IAM policy example uses the `put-resource-policy` AWS CLI command to attach a resource-based policy to an existing table. This example allows the user *John* to perform the GetItem, PutItem, UpdateItem, and UpdateTable API actions on an existing table named *MusicCollection*.

Remember to replace the *italicized* text with your resource-specific information.

```
aws dynamodb put-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
    --policy \
        "{
            \"Version\": \"2012-10-17\",
            \"Statement\": [
              {
                    \"Effect\": \"Allow\",
                    \"Principal\": {
                        \"AWS\": \"arn:aws:iam::111122223333:user/John\"
                    },
                    \"Action\": [
                        \"dynamodb:GetItem\",
                        \"dynamodb:PutItem\",
                        \"dynamodb:UpdateItem\",
                        \"dynamodb:UpdateTable\"
                    ],
                    \"Resource\": \"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection\"
                }
            ]
        }"
```

AWS CLI example to conditionally update an existing policy

To conditionally update an existing resource-based policy of a table, you can use the optional `expected-revision-id` parameter. The following example will only update the policy if it exists in DynamoDB and its current revision ID matches the provided `expected-revision-id` parameter.

```
aws dynamodb put-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
    --expected-revision-id 1709841168699 \
    --policy \
        "{
            \"Version\": \"2012-10-17\",
            \"Statement\": [
              {
                    \"Effect\": \"Allow\",
                    \"Principal\": {
                        \"AWS\": \"arn:aws:iam::111122223333:user/John\"
                    },
```

```
                    \"Action\": [
                        \"dynamodb:GetItem\",
                        \"dynamodb:UpdateItem\",
                        \"dynamodb:UpdateTable\"
                    ],
                    \"Resource\": \"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection\"
                }
            ]
        }"
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. From the dashboard, choose an existing table.
3. Navigate to the **Permissions** tab, and choose **Create table policy**.
4. In the resource-based policy editor, add the policy you would like to attach and choose **Create policy**.

   The following IAM policy example allows the user *John* to perform the GetItem, PutItem, UpdateItem, and UpdateTable API actions on an existing table named *MusicCollection*.

   Remember to replace the *italicized* text with your resource-specific information.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:user/username"
      },
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:UpdateTable"
```

```
      ],
      "Resource": "arn:aws:dynamodb:us-
east-1:123456789012:table/MusicCollection"
    }
  ]
}
```

AWS SDK for Java 2.x

The following IAM policy example uses the `putResourcePolicy` method to attach a resource-based policy to an existing table. This policy allows a user to perform the GetItem API action on an existing table.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.PutResourcePolicyRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * Get started with the AWS SDK for Java 2.x
 */
public class PutResourcePolicy {

    public static void main(String[] args) {
        final String usage = """

                Usage:
                    <tableArn> <allowedAWSPrincipal>

                Where:
                    tableArn - The Amazon DynamoDB table ARN to attach the policy to.
 For example, arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection.
                    allowedAWSPrincipal - Allowed AWS principal ARN that the example
 policy will give access to. For example, arn:aws:iam::123456789012:user/John.
                """;

        if (args.length != 2) {
```

```
            System.out.println(usage);
            System.exit(1);
        }

        String tableArn = args[0];
        String allowedAWSPrincipal = args[1];
        System.out.println("Attaching a resource-based policy to the Amazon DynamoDB
table with ARN " +
                tableArn);
        Region region = Region.US_WEST_2;
        DynamoDbClient ddb = DynamoDbClient.builder()
                .region(region)
                .build();

        String result = putResourcePolicy(ddb, tableArn, allowedAWSPrincipal);
        System.out.println("Revision ID for the attached policy is " + result);
        ddb.close();
    }

    public static String putResourcePolicy(DynamoDbClient ddb, String tableArn, String
allowedAWSPrincipal) {
        String policy = generatePolicy(tableArn, allowedAWSPrincipal);
        PutResourcePolicyRequest request = PutResourcePolicyRequest.builder()
                .policy(policy)
                .resourceArn(tableArn)
                .build();

        try {
            return ddb.putResourcePolicy(request).revisionId();
        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }

        return "";
    }

    private static String generatePolicy(String tableArn, String allowedAWSPrincipal) {
        return "{\n" +
                "    \"Version\": \"2012-10-17\",\n" +,
                "    \"Statement\": [\n" +
                "        {\n" +
                "            \"Effect\": \"Allow\",\n" +
```

```
                "            \"Principal\": {\"AWS\":\"" + allowedAWSPrincipal + "\"},
\n" +
                "            \"Action\": [\n" +
                "                \"dynamodb:GetItem\"\n" +
                "            ],\n" +
                "            \"Resource\": \"" + tableArn + "\"\n" +
                "        }\n" +
                "    ]\n" +
                "}";
    }
}
```

Attach a resource-based policy to a DynamoDB stream

You can attach a resource-based policy to an existing table's stream or modify an existing policy by using the DynamoDB console, PutResourcePolicy API, the AWS CLI, AWS SDK, or an CloudFormation template.

> **Note**
>
> You can't attach a policy to a stream while creating it using the CreateTable or UpdateTable APIs. However, you can modify or delete a policy after a table is deleted. You can also modify or delete the policy of a disabled stream.

AWS CLI

The following IAM policy example uses the `put-resource-policy` AWS CLI command to attach a resource-based policy to the stream of a table named *`MusicCollection`*. This example allows the user *`John`* to perform the GetRecords, GetShardIterator, and DescribeStream API actions on the stream.

Remember to replace the *`italicized`* text with your resource-specific information.

```
aws dynamodb put-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection/
stream/2024-02-12T18:57:26.492 \
    --policy \
        "{
            \"Version\": \"2012-10-17\",
            \"Statement\": [
```

```
            {
                  \"Effect\": \"Allow\",
                  \"Principal\": {
                      \"AWS\": \"arn:aws:iam::111122223333:user/John\"
                  },
                  \"Action\": [
                      \"dynamodb:GetRecords\",
                      \"dynamodb:GetShardIterator\",
                      \"dynamodb:DescribeStream\"
                  ],
                  \"Resource\": \"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection/stream/2024-02-12T18:57:26.492\"
                }
            ]
        }"
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. On the DynamoDB console dashboard, choose **Tables** and then select an existing table.

   Make sure the table you select has streams turned on. For information about turning on streams for a table, see Enabling a stream.
3. Choose the **Permissions** tab.
4. In **Resource-based policy for active stream**, choose **Create stream policy**.
5. In the **Resource-based policy** editor, add a policy to define the access permissions for the stream. In this policy, you specify who has access to the stream and the actions they are allowed to perform on the stream. To add a policy, do one of the following:

   - Type or paste a JSON policy document. For details about the IAM policy language, see Creating policies using the JSON editor in the *IAM User Guide*.

     > **Tip**
     >
     > To see examples of resource-based policies in the Amazon DynamoDB Developer Guide, choose **Policy examples**.

   - Choose **Add new statement** to add a new statement and enter the information in the provided fields. Repeat this step for as many statements as you would like to add.

> **Important**
>
> Make sure that you resolve any security warnings, errors, or suggestions before you save your policy.

6. (Optional) Choose **Preview external access** in the lower-right corner to preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to create an account analyzer in IAM Access Analyzer. For more information, see Preview access.
7. Choose **Create policy**.

The following IAM policy example attaches a resource-based policy to the stream of a table named *MusicCollection*. This example allows the user *John* to perform the GetRecords, GetShardIterator, and DescribeStream API actions on the stream.

Remember to replace the *italicized* text with your resource-specific information.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:user/username"
      },
      "Action": [
        "dynamodb:GetRecords",
        "dynamodb:GetShardIterator",
        "dynamodb:DescribeStream"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection/
stream/2024-02-12T18:57:26.492"
      ]
    }
```

```
  ]
}
```

Remove a resource-based policy from a DynamoDB table

You can delete a resource-based policy from an existing table by using the DynamoDB console, DeleteResourcePolicy API, the AWS CLI, AWS SDK, or an CloudFormation template.

AWS CLI

The following example uses the `delete-resource-policy` AWS CLI command to remove a resource-based policy from a table named *`MusicCollection`*.

Remember to replace the *`italicized`* text with your resource-specific information.

```
aws dynamodb delete-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. On the DynamoDB console dashboard, choose **Tables** and then select an existing table.
3. Choose **Permissions**.
4. From the **Manage policy** dropdown, choose **Delete policy**.
5. In the **Delete resource-based policy for table** dialog box, type **`confirm`** to confirm the delete action.
6. Choose **Delete**.

Cross-account access with resource-based policies in DynamoDB

Using a resource-based policy, you can provide cross-account access to resources available in different AWS accounts. All cross-account access allowed by the resource-based policies will be reported through IAM Access Analyzer external access findings if you have an analyzer in the same AWS Region as the resource. IAM Access Analyzer runs policy checks to validate your policy against IAM policy grammar and best practices. These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best

practices. You can view the active findings from IAM Access Analyzer in the **Permissions** tab of the DynamoDB console.

For information about validating policies by using IAM Access Analyzer, see IAM Access Analyzer policy validation in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see IAM Access Analyzer policy check reference.

To grant GetItem permission to a user A in account A for accessing a table B in account B, perform the following steps:

1. Attach a resource-based policy to table B that grants permission to user A for performing the `GetItem` action.
2. Attach an identity-based policy to user A that grants it permission to perform the `GetItem` action on table B.

Using the **Preview external access** option available in DynamoDB console, you can preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to create an account analyzer in IAM Access Analyzer. For more information, see Preview access.

The table name parameter in the DynamoDB data plane and control plane APIs accept complete Amazon Resource Name (ARN) of the table to support cross-account operations. If you only provide the table name parameter instead of a complete ARN, the API operation will be performed on the table in the account to which the requestor belongs. For an example of a policy that uses cross-account access, see Resource-based policy for cross-account access.

The resource owner's account will be charged even when a principal from another account is reading from or writing to the DynamoDB table in the owner's account. If the table has provisioned throughput, the sum of all the requests from the owner accounts and the requestors in other accounts will determine if the request will be throttled (if autoscaling is disabled) or scaled up/down if autoscaling is enabled.

The requests will be logged in the CloudTrail logs of both the owner and the requestor accounts so that each of the two accounts can track which account accessed what data.

Share access with cross-account AWS Lambda functions

Lambda functions in account A

1. Go to the IAM console to create an IAM role that will be used as the Lambda execution role for your AWS Lambda function in account A. Add the managed IAM policy `AWSLambdaDynamoDBExecutionRole` which has the required DynamoDB Streams and Lambda invocation permissions. This policy also grants access to all potential DynamoDB Streams resources you may have access to in account A.
2. In the Lambda console, create an AWS Lambda function to process records in a DynamoDB stream and during the setup for the execution role, choose the role you created in the previous step.
3. Provide the Lambda function execution role to the DynamoDB Streams' owner of account B to configure the resource-based policy for cross-account read access.
4. Finish setting up the Lambda function.

DynamoDB Stream in Account B

1. Get the cross-account Lambda execution role from account A that will invoke the Lambda function.
2. On the Amazon DynamoDB console in account B, choose the table for Lambda cross-account trigger. Under the **Exports and streams** tab, locate your DynamoDB stream ARN. Make sure that DynamoDB Stream status is On and note the full stream ARN as you will need it for the resource policy.
3. Under the **Permissions** tab, choose **create stream policy** to start the visual policy editor. Choose **Add new statement** or edit the policy if one already exists.
4. Create a policy that specifies the Lambda execution role in account A as the principal, and grant the required DynamoDB Streams actions. Make sure to include the actions `dynamodb:DescribeStream`, `dynamodb:GetRecords`, and `dynamodb:GetShardIterator`. For more information about example resource policies for DynamoDB Streams, see DynamoDB resource-based policy examples.

> **Note**
>
> The cross-account access of control plane APIs has a lower transactions per second (TPS) limit of 500 requests.

Blocking public access with resource-based policies in DynamoDB

Block Public Access (BPA) is a feature that identifies and prevents the attaching of resource-based policies that grant public access to your DynamoDB tables, indexes, or streams across your Amazon Web Services (AWS) accounts. With BPA, you can prevent public access to your DynamoDB resources. BPA performs checks during the creation or modification of a resource-based policy and helps improve your security posture with DynamoDB. BPA is automatically enforced during these operations; there is no separate setting or configuration to enable it.

BPA uses automated reasoning to analyze the access granted by your resource-based policy and alerts you if such permissions are found at the time of administering a resource-based policy. The analysis verifies access across all resource-based policy statements, actions, and the set of condition keys used in your policies.

> **Important**
>
> BPA helps protect your resources by preventing public access from being granted through the resource-based policies that are directly attached to your DynamoDB resources, such as tables, indexes, and streams. In addition to using BPA, carefully inspect the following policies to confirm that they do not grant public access:
>
> - Identity-based policies attached to associated AWS principals (for example, IAM roles)
> - Resource-based policies attached to associated AWS resources (for example, AWS Key Management Service (KMS) keys)

You must make sure that the principal doesn't include a * entry or that one of the specified condition keys restrict access from principals to the resource. If the resource-based policy grants public access to your table, indexes, or stream across AWS accounts, DynamoDB will block you from creating or modifying the policy until the specification within the policy is corrected and deemed non-public.

You can make a policy non-public by specifying one or more principals inside the `Principal` block. The following resource-based policy example blocks public access by specifying two principals.

```
{
  "Effect": "Allow",
```

```
  "Principal": {
    "AWS": [
      "123456789012",
      "111122223333"
    ]
  },
  "Action": "dynamodb:*",
  "Resource": "*"
}
```

Policies that restrict access by specifying certain condition keys are also not considered public. Along with evaluation of the principal specified in the resource-based policy, the following trusted condition keys are used to complete the evaluation of a resource-based policy for non-public access:

- `aws:PrincipalAccount`
- `aws:PrincipalArn`
- `aws:PrincipalOrgID`
- `aws:PrincipalOrgPaths`
- `aws:SourceAccount`
- `aws:SourceArn`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserId`
- `aws:PrincipalServiceName`
- `aws:PrincipalServiceNamesList`
- `aws:PrincipalIsAWSService`
- `aws:Ec2InstanceSourceVpc`
- `aws:SourceOrgID`
- `aws:SourceOrgPaths`

Additionally, for a resource-based policy to be non-public, the values for Amazon Resource Name (ARN) and string keys must not contain wildcards or variables. If your resource-based policy uses the `aws:PrincipalIsAWSService` key, you must make sure that you've set the key value to true.

The following policy limits access to the user `John` in the specified account. The condition makes the `Principal` constrained and not be considered as public.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "*"
  },
  "Action": "dynamodb:*",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "aws:PrincipalArn": "arn:aws:iam::123456789012:user/John"
    }
  }
}
```

The following example of a non-public resource-based policy constrains `sourceVPC` using the `StringEquals` operator.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "dynamodb:*",
      "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/
MusicCollection",
      "Condition": {
        "StringEquals": {
          "aws:SourceVpc": [
            "vpc-91237329"
          ]
        }
      }
    }
  ]
```

```
}
```

DynamoDB API operations supported by resource-based policies

This topic lists the API operations that are supported by resource-based policies. However, for cross-account access, you can only use a certain set of DynamoDB APIs through resource-based policies. You can't attach resource-based policies to resource types, such as backups and imports. The IAM actions, which correspond with the APIs operating on these resource types, are excluded from the supported IAM actions in resource-based policies. Because table administrators configure internal table settings within the same account, APIs, such as UpdateTimeToLive and DisableKinesisStreamingDestination, don't support cross-account access through resource-based policies.

The DynamoDB data plane and control plane APIs that support cross-account access also support table name overloading, which lets you specify the table ARN instead of the table name. You can specify table ARN in the `TableName` parameter of these APIs. However, not all of these APIs support cross-account access.

Data plane API operations

The following table lists the API-level support provided by data plane API operations for resource-based policies and cross-account access.

Data Plane - Tables/indexes APIs	Resource-based policy support	Cross-account support
DeleteItem	Yes	Yes
GetItem	Yes	Yes
PutItem	Yes	Yes
Query	Yes	Yes
Scan	Yes	Yes
UpdateItem	Yes	Yes
TransactGetItems	Yes	Yes
TransactWriteItems	Yes	Yes
BatchGetItem	Yes	Yes
BatchWriteItem	Yes	Yes

PartiQL API operations

The following table lists the API-level support provided by PartiQL API operations for resource-based policies and cross-account access.

PartiQL APIs	Resource-based policy support	Cross-account support
BatchExecuteStatement	Yes	No

PartiQL APIs	Resource-based policy support	Cross-account support
ExecuteStatement	Yes	No
ExecuteTransaction	Yes	No

Control plane API operations

The following table lists the API-level support provided by control plane API operations for resource-based policies and cross-account access.

Control Plane - Tables APIs	Resource-based policy support	Cross-account support
CreateTable	No	No
DeleteTable	Yes	Yes
DescribeTable	Yes	Yes
UpdateTable	Yes	Yes

Version 2019.11.21 (Current) global tables API operations

The following table lists the API-level support provided by Version 2019.11.21 (Current) global tables API operations for resource-based policies and cross-account access.

Version 2019.11.21 (Current) global tables APIs	Resource-based policy support	Cross-account support
DescribeTableReplicaAutoScaling	Yes	No
UpdateTableReplicaAutoScaling	Yes	No

Version 2017.11.29 (Legacy) global tables API operations

The following table lists the API-level support provided by Version 2017.11.29 (Legacy) global tables API operations for resource-based policies and cross-account access.

Version 2017.11.29 (Legacy) global tables APIs	Resource-based policy support	Cross-account support
CreateGlobalTable	No	No
DescribeGlobalTable	No	No
DescribeGlobalTableSettings	No	No
ListGlobalTables	No	No
UpdateGlobalTable	No	No
UpdateGlobalTableSettings	No	No

Tags API operations

The following table lists the API-level support provided by API operations related to tags for resource-based policies and cross-account access.

Tags APIs	Resource-based policy support	Cross-account support
ListTagsOfResource	Yes	Yes
TagResource	Yes	Yes
UntagResource	Yes	Yes

Backup and Restore API operations

The following table lists the API-level support provided by API operations related to backup and restore for resource-based policies and cross-account access.

Backup and Restore APIs	Resource-based policy support	Cross-account support
CreateBackup	Yes	No
DescribeBackup	No	No
DeleteBackup	No	No
RestoreTableFromBackup	No	No

Continuous Backup/Restore (PITR) API operations

The following table lists the API-level support provided by API operations related to Continuous Backup/Restore (PITR) for resource-based policies and cross-account access.

Continuous Backup/Restore (PITR) APIs	Resource-based policy support	Cross-account support
DescribeContinuousBackups	Yes	No
RestoreTableToPointInTime	Yes	No
UpdateContinuousBackups	Yes	No

Contributor Insights API operations

The following table lists the API-level support provided by API operations related to Continuous Backup/Restore (PITR) for resource-based policies and cross-account access.

Contributor Insights APIs	Resource-based policy support	Cross-account support
DescribeContributorInsights	Yes	No
ListContributorInsights	No	No
UpdateContributorInsights	Yes	No

Export API operations

The following table lists the API-level support provided by Export API operations for resource-based policies and cross-account access.

Export APIs	Resource-based policy support	Cross-account support
DescribeExport	No	No
ExportTableToPointInTime	Yes	No
ListExports	No	No

Import API operations

The following table lists the API-level support provided by Import API operations for resource-based policies and cross-account access.

Import APIs	Resource-based policy support	Cross-account support
DescribeImport	No	No
ImportTable	No	No
ListImports	No	No

Amazon Kinesis Data Streams API operations

The following table lists the API-level support provided by Kinesis Data Streams API operations for resource-based policies and cross-account access.

Kinesis APIs	Resource-based policy support	Cross-account support
DescribeKinesisStreamingDestination	Yes	No
DisableKinesisStreamingDestination	Yes	No
EnableKinesisStreamingDestination	Yes	No
UpdateKinesisStreamingDestination	Yes	No

Resource-based policy API operations

The following table lists the API-level support provided by resource-based policy API operations for resource-based policies and cross-account access.

Resource-based policy APIs	Resource-based policy support	Cross-account support
GetResourcePolicy	Yes	No
PutResourcePolicy	Yes	No
DeleteResourcePolicy	Yes	No

Time-to-Live API operations

The following table lists the API-level support provided by time to live (TTL) API operations for resource-based policies and cross-account access.

TTL APIs	Resource-based policy support	Cross-account support
DescribeTimeToLive	Yes	No
UpdateTimeToLive	Yes	No

Other API operations

The following table lists the API-level support provided by other miscellaneous API operations for resource-based policies and cross-account access.

Other APIs	Resource-based policy support	Cross-account support
DescribeLimits	No	No
DescribeEndpoints	No	No
ListBackups	No	No
ListTables	No	No

DynamoDB Streams API operations

The following table lists the API-level support of DynamoDB Streams APIs for resource-based policies and cross-account access.

DynamoDB Streams APIs	Resource-based policy support	Cross-account support
DescribeStream	Yes	Yes
GetRecords	Yes	Yes
GetShardIterator	Yes	Yes
ListStreams	No	No

Authorization with IAM identity-based policies and DynamoDB resource-based policies

Identity-based policies are attached to an identity, such as IAM users, groups of users, and roles. These are IAM policy documents that control what actions an identity can perform, on which resources, and under what conditions. Identity-based policies can be managed or inline policies.

Resource-based policies are IAM policy documents that you attach to a resource, such as a DynamoDB table. These policies grant the specified principal permission to perform specific actions on that resource and defines under what conditions this applies. For example, the resource-based policy for a DynamoDB table also includes the index associated with the table. Resource-based policies are inline policies. There are no managed resource-based policies.

For more information about these policies, see Identity-based policies and resource-based policies in the *IAM User Guide*.

If the IAM principal is from the same account as the resource owner, a resource-based policy is sufficient to specify access permissions to the resource. You can still choose to have an IAM identity-based policy along with a resource-based policy. For cross-account access, you must explicitly allow access in both the identity and resource policies as specified in Cross-account access with resource-based policies in DynamoDB. When you use both types of policies, a policy is evaluated as described in Determining whether a request is allowed or denied within an account.

> **Important**
>
> If an identity-based policy grants unconditional access to a DynamoDB table (for example, `dynamodb:GetItem` with no conditions), a resource-based policy that allows access with conditions on `dynamodb:Attributes` won't restrict that access. The identity-based policy's unconditional allow takes precedence, and the resource-based policy's conditions are not applied as restrictions. To restrict access to specific attributes, use an explicit `Deny` statement instead of relying solely on conditional `Allow` statements in the resource-based policy.

DynamoDB resource-based policy examples

When you specify an ARN in the `Resource` field of a resource-based policy, the policy takes effect only if the specified ARN matches the ARN of the DynamoDB resource to which it is attached.

> **Note**
>
> Remember to replace the *italicized* text with your resource-specific information.

Resource-based policy for a table

The following resource-based policy attached to a DynamoDB table named *MusicCollection*, gives the IAM users *John* and *Jane* permission to perform GetItem and BatchGetItem actions on the *MusicCollection* resource.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "1111",
        "Effect": "Allow",
        "Principal": {
          "AWS": [
            "arn:aws:iam::111122223333:user/username",
            "arn:aws:iam::111122223333:user/Jane"
          ]
        },
        "Action": [
          "dynamodb:GetItem",
          "dynamodb:BatchGetItem"
        ],
        "Resource": [
          "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection"
        ]
    }
  ]
}
```

Resource-based policy for a stream

The following resource-based policy attached to a DynamoDB stream named `2024-02-12T18:57:26.492` gives the IAM users *John* and *Jane* permission to perform GetRecords, GetShardIterator, and DescribeStream API actions on the `2024-02-12T18:57:26.492` resource.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "1111",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::111122223333:user/username",
          "arn:aws:iam::111122223333:user/Jane"
        ]
      },
      "Action": [
        "dynamodb:DescribeStream",
        "dynamodb:GetRecords",
        "dynamodb:GetShardIterator"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection/
stream/2024-02-12T18:57:26.492"
      ]
    }
  ]
}
```

Resource-based policy for access to perform all actions on specified resources

To allow a user to perform all actions on a table and all associated indexes with a table, you can use a wildcard (*) to represent the actions and the resources associated with the table. Using a

wild card character for the resources, will allow the user access to the DynamoDB table and all its associated indexes, including the ones that haven't yet been created. For example, the following policy will give the user *John* permission to perform any actions on the *MusicCollection* table and all of its indexes, including any indexes that will be created in the future.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "1111",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:user/username"
      },
      "Action": "dynamodb:*",
      "Resource": [
        "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection",
        "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection/
index/index-name"
      ]
    }
  ]
}
```

Resource-based policy for cross-account access

You can specify permissions for a cross-account IAM identity to access DynamoDB resources. For example, you might need a user from a trusted account to get access to read the contents of your table, with the condition that they access only specific items and specific attributes in those items. The following policy allows access to user *John* from a trusted AWS account ID *111111111111* to access data from a table in account *123456789012* by using the GetItem API. The policy ensures that the user can access only items with a primary key *Jane* and that the user can only retrieve the attributes `Artist` and `SongTitle`, but no other attributes.

> **Important**
>
> If you do not specify the `SPECIFIC_ATTRIBUTES` condition, you'll see all attributes for the items returned.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CrossAccountTablePolicy",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111111111111:user/John"
            },
            "Action": "dynamodb:GetItem",
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection"
            ],
            "Condition": {
                "ForAllValues:StringEquals": {
                    "dynamodb:LeadingKeys": "Jane",
                    "dynamodb:Attributes": [
                        "Artist",
                        "SongTitle"
                    ]
                },
                "StringEquals": {
                    "dynamodb:Select": "SPECIFIC_ATTRIBUTES"
                }
            }
        }
    ]
}
```

In addition to the preceding resource-based policy, the identity-based policy attached to the user *John* also needs to allow the `GetItem` API action for the cross-account access to work. The following is an example of an identity-based policy that you must attach to the user *John*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CrossAccountIdentityBasedPolicy",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection"
            ],
            "Condition": {
                "ForAllValues:StringEquals": {
                    "dynamodb:LeadingKeys": "Jane",
                    "dynamodb:Attributes": [
                        "Artist",
                        "SongTitle"
                    ]
                },
                "StringEquals": {
                    "dynamodb:Select": "SPECIFIC_ATTRIBUTES"
                }
            }
        }
    ]
}
```

The user John can make a `GetItem` request by specifying the table ARN in the `table-name` parameter for accessing the table *`MusicCollection`* in the account *`123456789012`*.

```
aws dynamodb get-item \
    --table-name arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
    --key '{"Artist": {"S": "Jane"}' \
    --projection-expression 'Artist, SongTitle' \
    --return-consumed-capacity TOTAL
```

Resource-based policy with IP address conditions

You can apply a condition to restrict source IP addresses, virtual private clouds (VPCs), and VPC endpoint (VPCE). You can specify permissions based on the source addresses of the originating request. For example, you might want to allow a user to access DynamoDB resources only if they are being accessed from a specific IP source, such as a corporate VPN endpoint. Specify these IP addresses in the `Condition` statement.

The following example allows the user *John* access to any DynamoDB resource when the source IPs are `54.240.143.0/24` and `2001:DB8:1234:5678::/64`.

JSON

```
{
  "Id":"PolicyId2",
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowIPmix",
      "Effect":"Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111111111111:user/username"
      },
      "Action":"dynamodb:*",
      "Resource":"*",
      "Condition": {
        "IpAddress": {
          "aws:SourceIp": [
            "54.240.143.0/24",
            "2001:DB8:1234:5678::/64"
          ]
        }
      }
    }
  ]
}
```

You can also deny all access to DynamoDB resources except when the source is a specific VPC endpoint, for example *vpce-1a2b3c4d*.

Important

A resource-based policy that contains only a `Deny` statement with `"Principal": "*"` denies access to every principal, including your own ability to update or delete the policy later. If you attach a policy that would lock you out in this way, DynamoDB rejects it with the following error: *The new resource policy will not allow you to update the resource policy in the future.* Adding a separate `Allow` statement does not resolve this, because an explicit `Deny` always overrides an `Allow`. To deny access to everyone except a specific VPC endpoint while retaining the ability to manage the policy, exempt the administering principal from the `Deny` statement by adding an `ArnNotEquals` condition on `aws:PrincipalArn`, as shown in the following example.

Important

When you use DAX with DynamoDB tables that have IP-based resource policies in IPv6-only environments, you must configure additional access rules. If your resource policy restricts access to the IPv4 address space `0.0.0.0/0` on tables, you must allow access for the IAM role associated with your DAX cluster. Add an `ArnNotEquals` condition to your policy to ensure DAX maintains access to your DynamoDB tables. For more information see, DAX and IPv6.

JSON

```
{
  "Id":"PolicyId",
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToSpecificVPCEOnly",
      "Principal": "*",
      "Action": "dynamodb:*",
      "Effect": "Deny",
      "Resource": "*",
      "Condition": {
        "StringNotEquals":{
          "aws:sourceVpce":"vpce-1a2b3c4d"
```

```
        },
        "ArnNotEquals":{
          "aws:PrincipalArn":"arn:aws:iam::123456789012:role/AdminRole"
        }
      }
    }
  ]
}
```

Resource-based policy using an IAM role

You can also specify an IAM service role in the resource-based policy. IAM entities that assume this role are bounded by the permissible actions specified for the role and to the specific set of resources within the resource-based policy.

The following example allows an IAM entity to perform all DynamoDB actions on the *MusicCollection* and *MusicCollection* DynamoDB resources.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "1111",
      "Effect": "Allow",
      "Principal": { "AWS": "arn:aws:iam::111122223333:role/role-name" },
      "Action": "dynamodb:*",
      "Resource": [
        "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection",
        "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection/*"
      ]
    }
  ]
}
```

DynamoDB resource-based policy considerations

When you define resource-based policies for your DynamoDB resources, the following considerations apply:

General considerations

- The maximum size supported for a resource-based policy document is 20 KB. DynamoDB counts whitespaces when calculating the size of a policy against this limit.
- Subsequent updates to a policy for a given resource are blocked for 15 seconds after a successful update of the policy for the same resource.
- Currently, you can only attach a resource-based policy to existing streams. You can't attach a policy to a stream while creating it.

Global table considerations

- Resource-based policies aren't supported for Global table version 2017.11.29 (Legacy) replicas.
- Within a resource-based policy, if the action for a DynamoDB service-linked role (SLR) to replicate data for a global table is denied, adding or deleting a replica will fail with an error.
- The AWS::DynamoDB::GlobalTable resource doesn’t support creating a replica and adding a resource-based policy to that replica in the same stack update in Regions other than the Region where you deploy the stack update.

Cross-account considerations

- Cross-account access using resource-based policies doesn't support encrypted tables with AWS managed keys because you can't grant cross-account access to the AWS managed KMS policy.

CloudFormation considerations

- Resource-based policies don't support drift detection. If you update a resource-based policy outside of the AWS CloudFormation stack template, you'll need to update the CloudFormation stack with the changes.
- Resource-based policies don't support out of band changes. If you add, update, or delete a policy outside of the CloudFormation template, the change won't be overwritten if there are no changes to the policy within the template.

For example, say that your template contains a resource-based policy which you later update outside of the template. If you don't make any changes to the policy in the template, the updated policy in DynamoDB won't be synced with the policy in the template.

Conversely, say that your template doesn't contain a resource-based policy, but you add a policy outside of the template. This policy won't be removed from DynamoDB as long as you don't add it to the template. When you add a policy to the template and update the stack, the existing policy in DynamoDB will be updated to match the one defined in the template.

DynamoDB resource-based policy best practices

This topic describes the best practices for defining access permissions for your DynamoDB resources and the actions allowed on these resources.

Simplify access control to DynamoDB resources

If the AWS Identity and Access Management principals that need access to a DynamoDB resource are part of the same AWS account as the resource owner, an IAM identity-based policy is not required for each principal. A resource-based policy that is attached to the given resources will suffice. This type of configuration simplifies access control.

Protect your DynamoDB resources with resource-based policies

For all DynamoDB tables and streams, create resource-based policies to enforce access control for these resources. Resource-based policies enable you to centralize permissions at the resource level, simplify access control to DynamoDB tables, indexes, and streams, and reduce administration overhead. If no resource-based policy is specified for a table or a stream, access to the table or stream will be implicitly denied, unless identity-based policies associated with the IAM principals allow access.

Apply least-privilege permissions

When you set permissions with resource-based policies for DynamoDB resources, grant only the permissions required to perform an action. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. You might start with broad permissions while you explore the permissions that are required for your workload or use case. As your use case matures, you can work to reduce the permissions that you grant to work toward least privilege.

Analyze cross-account access activity for generating least-privilege policies

IAM Access Analyzer reports cross-account access to external entities specified in resource-based policies, and provides visibility to help you refine permissions and conform to least privilege. For more information about policy generation, see IAM Access Analyzer policy generation.

Use IAM Access Analyzer to generate least-privilege policies

To grant only the permissions required to perform a task, you can generate policies based on your access activity that is logged in AWS CloudTrail. IAM Access Analyzer analyzes the services and actions that your policies use.

Using attribute-based access control with DynamoDB

Attribute-based access control (ABAC) is an authorization strategy that defines access permissions based on tag conditions in your identity-based policies or other AWS policies, such as resource-based policies and organization IAM policies. You can attach tags to DynamoDB tables, which are then evaluated against the tag-based conditions. The indexes associated with a table inherit the tags you add to the table. You can add up to 50 tags for each DynamoDB table. The maximum size supported for all the tags in a table is 10 KB. For more information about tagging DynamoDB resources and tagging restrictions, see Tagging resources in DynamoDB and the section called "Tagging restrictions in DynamoDB".

For more information about using tags to control access to AWS resources, see the following topics in the IAM User Guide:

- What is ABAC for AWS
- Controlling access to AWS resources using tags

Using ABAC, you can enforce different access levels for your teams and applications to perform actions on DynamoDB tables using fewer policies. You can specify a tag in the condition element of an IAM policy to control access to your DynamoDB tables or indexes. These conditions determine the level of access an IAM principal, a user, or role, has to DynamoDB tables and indexes. When an IAM principal makes an access request to DynamoDB, the resource and identity's tags are evaluated against the tag conditions in the IAM policy. Thereafter, the policy becomes effective only if tag conditions are met. This enables you to create an IAM policy that effectively says one of the following:

- *Allow the user to manage only those resources that have a tag with a key X and a value Y.*
- *Deny access to all users to resources tagged with a key X.*

For example, you can create a policy that allows users to update a table only if it has the tag key-value pair: `"environment": "staging"`. You can use the aws:ResourceTag condition key to allow or deny access to a table based on the tags that are attached to that table.

You can include attribute-based conditions while creating the policy or later using the AWS Management Console, AWS API, AWS Command Line Interface (AWS CLI), AWS SDK, or AWS CloudFormation.

The following example allows the UpdateItem action on a table named `MusicTable` if it includes a tag key with the name `environment` and value `production`.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:UpdateItem"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/MusicTable",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/environment": "production"
        }
      }
    }
  ]
}
```

Topics

- Why should I use ABAC?
- Condition keys to implement ABAC with DynamoDB
- Considerations for using ABAC with DynamoDB

- Using attribute-based access control with DynamoDB tables and indexes
- Using attribute-based access control with DynamoDB Streams

Why should I use ABAC?

- **Simpler policy management:** You use fewer policies because you don't have to create different policies to define the level of access for each IAM principal.
- **Scalable access control:** Scaling access control is easier with ABAC because you don't have to update your policies when you create new DynamoDB resources. You can use tags to authorize access to IAM principals that contain tags matching the resource's tags. You can onboard new IAM principals or DynamoDB resources and apply appropriate tags to automatically grant the necessary permissions without having to make any policy changes.
- **Fine-grained permission management:** It's a best practice to grant least privilege when you create policies. Using ABAC, you can create tags for the IAM principal, and use them to grant access to specific actions and resources that match the tags on the IAM principal.
- **Alignment with corporate directory:** You can map tags with existing employee attributes from your corporate directory to align your access control policies with your organizational structure.

Condition keys to implement ABAC with DynamoDB

You can use the following condition keys in your AWS policies to control the level of access to your DynamoDB tables and indexes:

- aws:ResourceTag/tag-key: Controls access based on whether or not the tag key-value pair on a DynamoDB table or index matches the tag key and value in a policy. This condition key is relevant to all APIs that operate on an existing table or index.

  The `dynamodb:ResourceTag` conditions are evaluated as if you didn't attach any tags to a resource.
- aws:RequestTag/tag-key: Allows comparing the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. This condition key is relevant to APIs that contain tags as part of the request payload. These APIs include CreateTable and TagResource.
- aws:TagKeys: Compares the tag keys in a request with the keys that you specify in the policy. This condition key is relevant to APIs that contain tags as part of the request payload. These APIs include `CreateTable`, `TagResource`, and `UntagResource`.

Considerations for using ABAC with DynamoDB

When you use ABAC with DynamoDB tables or indexes, the following considerations apply:

- For information about using ABAC with DynamoDB Streams, see Using attribute-based access control with DynamoDB Streams.
- Tagging and ABAC aren't supported for DynamoDB backups. To use ABAC with backups, we recommend that you use AWS Backup.
- Tags aren't preserved in restored tables. You need to add tags to restored tables before you can use tag-based conditions in your policies.

Using attribute-based access control with DynamoDB tables and indexes

The following topics describe how to enable, use, and troubleshoot attribute-based access control (ABAC) for DynamoDB tables and indexes.

Topics

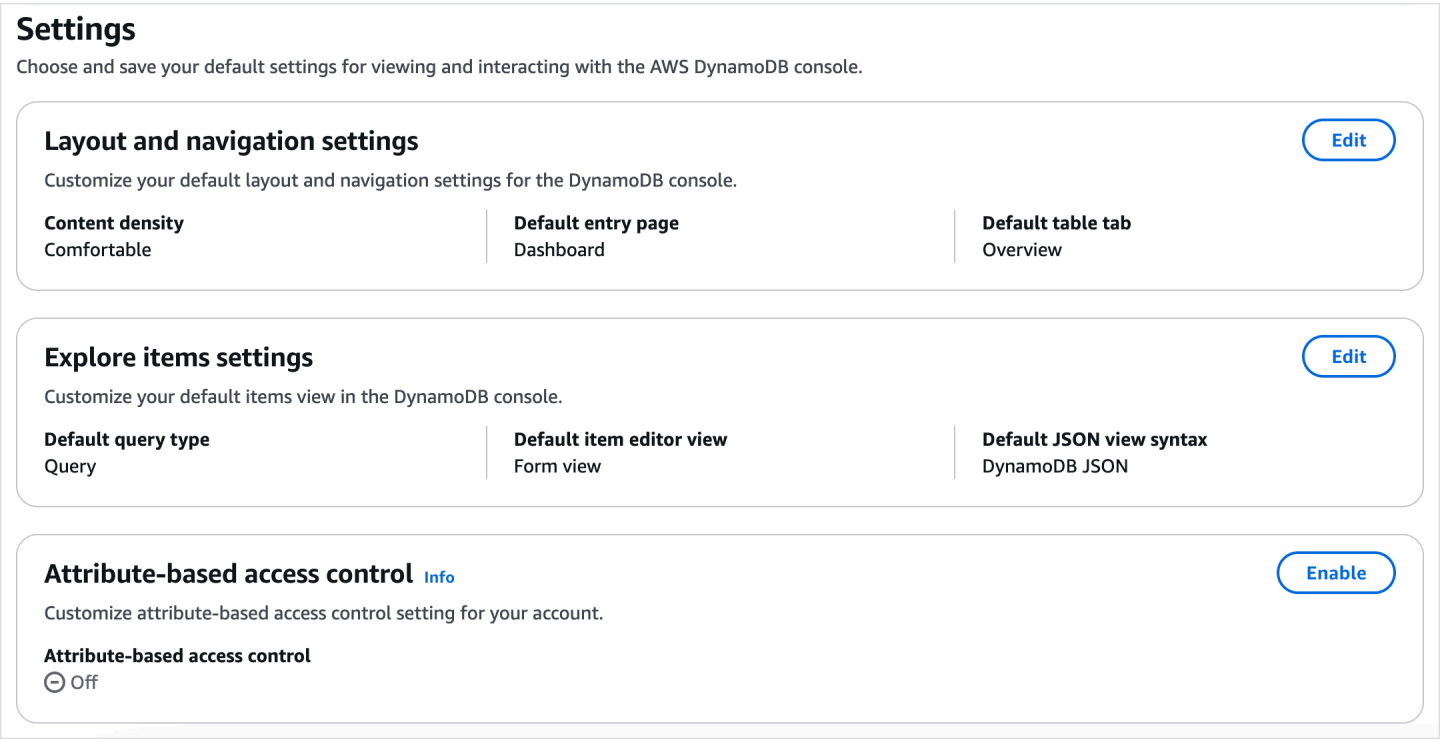
- Enabling ABAC in DynamoDB
- Get started with ABAC for DynamoDB tables and indexes
- Examples for using ABAC with DynamoDB tables and indexes
- Troubleshooting common ABAC errors for DynamoDB tables and indexes

Enabling ABAC in DynamoDB

For most of the AWS accounts, ABAC is enabled by default. Using the DynamoDB console, you can confirm if ABAC is enabled for your account. To do this, make sure that you open the DynamoDB console with a role that has the dynamodb:GetAbacStatus permission. Then, open the **Settings** page of the DynamoDB console.

If you don’t see the **Attribute-based access control** card or if the card displays a status of **On**, it means ABAC is enabled for your account. However, if you see the **Attribute-based access control** card with a status of **Off**, as shown in the following image, ABAC isn’t enabled for your account.

Attribute-based access control – not enabled



ABAC isn't enabled for AWS accounts for which tag-based conditions specified in their identity-based policies or other policies still need to be audited. If ABAC isn't enabled for your account, the tag-based conditions in your policies that are intended to act on DynamoDB tables or indexes are evaluated as if no tags are present for your resources or API requests. When ABAC is enabled for your account, the tag-based conditions in the policies of your account are evaluated considering the tags attached to your tables or API requests.

To enable ABAC for your account, we recommend that you first audit your policies as described in the Policy audit section. Then, include the required permissions for ABAC in your IAM policy. Finally, perform the steps described in Enabling ABAC in console to enable ABAC for your account in the current Region. After you enable ABAC, you can opt out within the next seven calendar days of opting in.

Topics

- Auditing your policies before enabling ABAC
- IAM permissions required to enable ABAC
- Enabling ABAC in console

Auditing your policies before enabling ABAC

Before you enable ABAC for your account, audit your policies to confirm that the tag-based conditions which might exist in the policies within your account are set up as intended. Auditing your policies will help avoid surprises from authorization changes with your DynamoDB workflows after ABAC is enabled. To view examples of using attribute-based conditions with tags, and the before and after behavior of ABAC implementation, see Examples for using ABAC with DynamoDB tables and indexes.

IAM permissions required to enable ABAC

You need the `dynamodb:UpdateAbacStatus` permission to enable ABAC for your account in the current Region. To confirm if ABAC is enabled for your account, you must also have the `dynamodb:GetAbacStatus` permission. With this permission, you can view the ABAC status for an account in any Region. You need these permissions in addition to the permission needed for accessing the DynamoDB console.

The following IAM policy grants the permission to enable ABAC and view its status for an account in the current Region.

```
{
"Version": "2012-10-17",        &TCX5-2025-waiver;
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:UpdateAbacStatus",
                "dynamodb:GetAbacStatus"
             ],
            "Resource": "*"
        }
    ]
}
```

Enabling ABAC in console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. From the top navigation pane, choose the Region for which you want to enable ABAC.
3. On the left navigation pane, choose **Settings**.

4. On the **Settings** page, do the following:

   a. In the **Attribute-based access control** card, choose **Enable**.

   b. In the **Confirm attribute-based access control setting** box, choose **Enable** to confirm your choice.

      This enables ABAC for the current Region and the **Attribute-based access control** card shows the status of **On**.

      If you want to opt out after enabling ABAC on the console, you can do so within the next seven calendar days of opting in. To opt out, choose **Disable** in the **Attribute-based access control** card on the **Settings** page.

      > **Note**
      >
      > Updating the status of ABAC is an asynchronous operation. If the tags in your policies aren't evaluated right away, you might need to wait for some time because the application of the changes is eventually consistent.

Get started with ABAC for DynamoDB tables and indexes

The following steps show how to set up permissions using ABAC. In this example scenario, you'll add tags to a DynamoDB table and create an IAM role with a policy that includes tag-based conditions. Then, you'll test the allowed permissions on the DynamoDB table by matching the tag conditions.

Topics

- Step 1: Add tags to a DynamoDB table
- Step 2: Create an IAM role with a policy including tag-based conditions
- Step 3: Test allowed permissions

Step 1: Add tags to a DynamoDB table

You can add tags to new or existing DynamoDB tables using the AWS Management Console, AWS API, AWS Command Line Interface (AWS CLI), AWS SDK, or AWS CloudFormation. For example, the following tag-resource CLI command adds a tag to a table named `MusicTable`.

```
aws dynamodb tag-resource –resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/
MusicTable –tags Key=environment,Value=staging
```

Step 2: Create an IAM role with a policy including tag-based conditions

Create an IAM policy using the aws:ResourceTag/tag-key condition key to compare the tag key-value pair that's specified in the IAM policy with the key-value pair that's attached to the table. The following example policy allows users to put or update items in tables if these tables contain the tag key-value pair: `"environment": "staging"`. If a table doesn't have the specified tag key-value pair, these actions are denied.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:PutItem",
                "dynamodb:UpdateItem"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/environment": "staging"
                }
            }
        }
    ]
}
```

Step 3: Test allowed permissions

1. Attach the IAM policy to a test user or role in your AWS account. Make sure that the IAM principal you use doesn't already have access to the DynamoDB table through a different policy.
2. Make sure that your DynamoDB table contains the `"environment"` tag key with a value of `"staging"`.

3. Perform the `dynamodb:PutItem` and `dynamodb:UpdateItem` actions on the tagged table. These actions should succeed if the `"environment": "staging"` tag key-value pair is present.

   If you perform these actions on a table that doesn't have the `"environment": "staging"` tag key-value pair, your request will fail with an `AccessDeniedException`.

You can also review the other sample use cases described in the following section to implement ABAC and perform more tests.

Examples for using ABAC with DynamoDB tables and indexes

The following examples depict some use cases to implement attribute-based conditions using tags.

Topics

- Example 1: Allow an action using aws:ResourceTag
- Example 2: Allow an action using aws:RequestTag
- Example 3: Deny an action using aws:TagKeys

Example 1: Allow an action using aws:ResourceTag

Using the `aws:ResourceTag/tag-key` condition key, you can compare the tag key-value pair that's specified in an IAM policy with the key-value pair that's attached in a DynamoDB table. For example, you can allow a specific action, such as PutItem, if the tag conditions match in an IAM policy and a table. To do this, perform the following steps:

Using the AWS CLI

1. Create a table. The following example uses the create-table AWS CLI command to create a table named `myMusicTable`.

```
aws dynamodb create-table \
  --table-name myMusicTable \
  --attribute-definitions AttributeName=id,AttributeType=S \
  --key-schema AttributeName=id,KeyType=HASH \
  --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
  --region us-east-1
```

2. Add a tag to this table. The following tag-resource AWS CLI command example adds the tag key-value pair `Title: ProductManager` to the `myMusicTable`.

```
aws dynamodb tag-resource --region us-east-1 --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/myMusicTable --tags Key=Title,Value=ProductManager
```

3. Create an inline policy and add it to a role which has the AmazonDynamoDBReadOnlyAccess AWS managed policy attached to it, as shown in the following example.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "dynamodb:PutItem",
      "Resource": "arn:aws:dynamodb:*:*:table/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Title": "ProductManager"
        }
      }
    }
  ]
}
```

   This policy allows the `PutItem` action on the table when the tag key and value attached to the table matches with the tags specified in the policy.

4. Assume the role with the policies described in Step 3.

5. Use the put-item AWS CLI command to put an item to the `myMusicTable`.

```
aws dynamodb put-item \
    --table-name myMusicTable --region us-east-1 \
    --item '{
        "id": {"S": "2023"},
        "title": {"S": "Happy Day"},
        "info": {"M": {
```

```
            "rating": {"N": "9"},
            "Artists": {"L": [{"S": "Acme Band"}, {"S": "No One You Know"}]},
            "release_date": {"S": "2023-07-21"}
        }}
    }'
```

6. Scan the table to verify if the item was added to the table.

```
aws dynamodb scan --table-name myMusicTable  --region us-east-1
```

Using the AWS SDK for Java 2.x

1. Create a table. The following example uses the CreateTable API to create a table named `myMusicTable`.

```
DynamoDbClient dynamoDB = DynamoDbClient.builder().region(region).build();
CreateTableRequest createTableRequest = CreateTableRequest.builder()
    .attributeDefinitions(
        Arrays.asList(
            AttributeDefinition.builder()
            .attributeName("id")
            .attributeType(ScalarAttributeType.S)
            .build()
        )
    )
    .keySchema(
        Arrays.asList(
            KeySchemaElement.builder()
            .attributeName("id")
            .keyType(KeyType.HASH)
            .build()
        )
    )
    .provisionedThroughput(ProvisionedThroughput.builder()
        .readCapacityUnits(5L)
        .writeCapacityUnits(5L)
        .build()
    )
    .tableName("myMusicTable")
    .build();
```

```
CreateTableResponse createTableResponse =
 dynamoDB.createTable(createTableRequest);
String tableArn = createTableResponse.tableDescription().tableArn();
String tableName = createTableResponse.tableDescription().tableName();
```

2. Add a tag to this table. The TagResource API in the following example adds the tag key-value pair `Title: ProductManager` to the `myMusicTable`.

```
TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
    .resourceArn(tableArn)
    .tags(
        Arrays.asList(
            Tag.builder()
            .key("Title")
            .value("ProductManager")
            .build()
        )
    )
    .build();
dynamoDB.tagResource(tagResourceRequest);
```

3. Create an inline policy and add it to a role which has the AmazonDynamoDBReadOnlyAccess AWS managed policy attached to it, as shown in the following example.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "dynamodb:PutItem",
      "Resource": "arn:aws:dynamodb:*:*:table/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Title": "ProductManager"
        }
      }
    }
  ]
```

```
}
```

This policy allows the `PutItem` action on the table when the tag key and value attached to the table matches with the tags specified in the policy.

4. Assume the role with the policies described in Step 3.
5. Use the PutItem API to put an item to the `myMusicTable`.

```
HashMap<String, AttributeValue> info = new HashMap<>();
info.put("rating", AttributeValue.builder().s("9").build());
info.put("artists", AttributeValue.builder().ss(List.of("Acme Band","No One You
 Know").build());
info.put("release_date", AttributeValue.builder().s("2023-07-21").build());

HashMap<String, AttributeValue> itemValues = new HashMap<>();
itemValues.put("id", AttributeValue.builder().s("2023").build());
itemValues.put("title", AttributeValue.builder().s("Happy Day").build());
itemValues.put("info", AttributeValue.builder().m(info).build());

PutItemRequest putItemRequest = PutItemRequest.builder()
                .tableName(tableName)
                .item(itemValues)
                .build();
dynamoDB.putItem(putItemRequest);
```

6. Scan the table to verify if the item was added to the table.

```
ScanRequest scanRequest = ScanRequest.builder()
                .tableName(tableName)
                .build();

ScanResponse scanResponse = dynamoDB.scan(scanRequest);
```

Using the AWS SDK for Python (Boto3)

1. Create a table. The following example uses the CreateTable API to create a table named `myMusicTable`.

```
create_table_response = ddb_client.create_table(
```

```
    AttributeDefinitions=[
        {
            'AttributeName': 'id',
            'AttributeType': 'S'
        },
    ],
    TableName='myMusicTable',
    KeySchema=[
        {
            'AttributeName': 'id',
            'KeyType': 'HASH'
        },
    ],
        ProvisionedThroughput={
        'ReadCapacityUnits': 5,
        'WriteCapacityUnits': 5
    },
)

table_arn = create_table_response['TableDescription']['TableArn']
```

2. Add a tag to this table. The TagResource API in the following example adds the tag key-value pair `Title: ProductManager` to the `myMusicTable`.

```
tag_resouce_response = ddb_client.tag_resource(
    ResourceArn=table_arn,
    Tags=[
        {
            'Key': 'Title',
            'Value': 'ProductManager'
        },
    ]
)
```

3. Create an inline policy and add it to a role which has the AmazonDynamoDBReadOnlyAccess AWS managed policy attached to it, as shown in the following example.

   JSON

```
{
    "Version":"2012-10-17",
```

```
    "Statement": [
        {
        "Effect": "Allow",
        "Action": "dynamodb:PutItem",
        "Resource": "arn:aws:dynamodb:*:*:table/*",
        "Condition": {
            "StringEquals": {
            "aws:ResourceTag/Title": "ProductManager"
            }
        }
        }
    ]
    }
```

This policy allows the `PutItem` action on the table when the tag key and value attached to the table matches with the tags specified in the policy.

4. Assume the role with the policies described in Step 3.
5. Use the PutItem API to put an item to the `myMusicTable`.

```
put_item_response = client.put_item(
    TableName = 'myMusicTable'
    Item = {
        'id': '2023',
        'title': 'Happy Day',
        'info': {
            'rating': '9',
            'artists': ['Acme Band','No One You Know'],
            'release_date': '2023-07-21'
        }
    }
)
```

6. Scan the table to verify if the item was added to the table.

```
scan_response = client.scan(
    TableName='myMusicTable'
)
```

Without ABAC

If ABAC isn't enabled for your AWS account, the tag conditions in the IAM policy and the DynamoDB table aren't matched. Consequently, the `PutItem` action returns an `AccessDeniedException` because of the effect of the `AmazonDynamoDBReadOnlyAccess` policy.

```
An error occurred (AccessDeniedException) when calling the PutItem operation:
 User: arn:aws:sts::123456789012:assumed-role/DynamoDBReadOnlyAccess/Alice is
 not authorized to perform: dynamodb:PutItem on resource: arn:aws:dynamodb:us-
east-1:123456789012:table/myMusicTable because no identity-based policy allows the
 dynamodb:PutItem action.
```

With ABAC

If ABAC is enabled for your AWS account, the `put-item` action completes successfully and adds a new item to your table. This is because the inline policy on the table allows the `PutItem` action if the tag conditions in the IAM policy and the table match.

Example 2: Allow an action using aws:RequestTag

Using the aws:RequestTag/tag-key condition key, you can compare the tag key-value pair that's passed in your request with the tag pair that's specified in the IAM policy. For example, you can allow a specific action, such as `CreateTable`, using the `aws:RequestTag` if the tag conditions don't match. To do this, perform the following steps:

Using the AWS CLI

1. Create an inline policy and add it to a role which has the AmazonDynamoDBReadOnlyAccess AWS managed policy attached to it, as shown in the following example.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:CreateTable",
                "dynamodb:TagResource"
```

```
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/Owner": "John"
                }
            }
        }
    ]
}
```

2. Create a table that contains the tag key-value pair of `"Owner": "John"`.

```
aws dynamodb create-table \
--attribute-definitions AttributeName=ID,AttributeType=S \
--key-schema AttributeName=ID,KeyType=HASH  \
--provisioned-throughput ReadCapacityUnits=1000,WriteCapacityUnits=500 \
--region us-east-1 \
--tags Key=Owner,Value=John \
--table-name myMusicTable
```

Using the AWS SDK for Python (Boto3)

1. Create an inline policy and add it to a role which has the AmazonDynamoDBReadOnlyAccess AWS managed policy attached to it, as shown in the following example.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:CreateTable",
                "dynamodb:TagResource"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*",
            "Condition": {
                "StringEquals": {
```

```
                    "aws:RequestTag/Owner": "John"
                }
            }
        }
    ]
}
```

2. Create a table that contains the tag key-value pair of `"Owner": "John"`.

```
ddb_client = boto3.client('dynamodb')

create_table_response = ddb_client.create_table(
    AttributeDefinitions=[
        {
            'AttributeName': 'id',
            'AttributeType': 'S'
        },
    ],
    TableName='myMusicTable',
    KeySchema=[
        {
            'AttributeName': 'id',
            'KeyType': 'HASH'
        },
    ],
        ProvisionedThroughput={
        'ReadCapacityUnits': 1000,
        'WriteCapacityUnits': 500
    },
    Tags=[
        {
            'Key': 'Owner',
            'Value': 'John'
        },
    ],
)
```

Without ABAC

If ABAC isn't enabled for your AWS account, the tag conditions in the inline policy and the DynamoDB table aren’t matched. Consequently, the `CreateTable` request fails and your table isn’t created.

```
An error occurred (AccessDeniedException) when calling the CreateTable operation:
 User: arn:aws:sts::123456789012:assumed-role/Admin/John is not authorized to perform:
 dynamodb:CreateTable on resource: arn:aws:dynamodb:us-east-1:123456789012:table/
myMusicTable because no identity-based policy allows the dynamodb:CreateTable action.
```

With ABAC

If ABAC is enabled for your AWS account, your table creation request completes successfully. Because the tag key-value pair of `"Owner": "John"` is present in the `CreateTable` request, the inline policy allows the user `John` to perform the `CreateTable` action.

Example 3: Deny an action using aws:TagKeys

Using the aws:TagKeys condition key, you can compare the tag keys in a request with the keys that are specified in the IAM policy. For example, you can deny a specific action, such as `CreateTable`, using `aws:TagKeys` if a specific tag key is *not* present in the request. To do this, perform the following steps:

Using the AWS CLI

1. Add a customer managed policy to a role which has the AmazonDynamoDBFullAccess AWS managed policy attached to it, as shown in the following example.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:CreateTable",
                "dynamodb:TagResource"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*",
            "Condition": {
                "Null": {
                    "aws:TagKeys": "false"
                },
                "ForAllValues:StringNotEquals": {
                    "aws:TagKeys": "CostCenter"
```

```
                }
            }
        }
    ]
}
```

2. Assume the role to which the policy was attached, and create a table with the tag key `Title`.

```
aws dynamodb create-table \
--attribute-definitions AttributeName=ID,AttributeType=S \
--key-schema AttributeName=ID,KeyType=HASH  \
--provisioned-throughput ReadCapacityUnits=1000,WriteCapacityUnits=500 \
--region us-east-1 \
--tags Key=Title,Value=ProductManager \
--table-name myMusicTable
```

Using the AWS SDK for Python (Boto3)

1. Add a customer managed policy to a role which has the AmazonDynamoDBFullAccess AWS managed policy attached to it, as shown in the following example.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:CreateTable",
                "dynamodb:TagResource"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*",
            "Condition": {
                "Null": {
                    "aws:TagKeys": "false"
                },
                "ForAllValues:StringNotEquals": {
                    "aws:TagKeys": "CostCenter"
                }
```

```
            }
        }
    ]
}
```

2. Assume the role to which the policy was attached, and create a table with the tag key `Title`.

```
ddb_client = boto3.client('dynamodb')

create_table_response = ddb_client.create_table(
    AttributeDefinitions=[
        {
            'AttributeName': 'id',
            'AttributeType': 'S'
        },
    ],
    TableName='myMusicTable',
    KeySchema=[
        {
            'AttributeName': 'id',
            'KeyType': 'HASH'
        },
    ],
        ProvisionedThroughput={
        'ReadCapacityUnits': 1000,
        'WriteCapacityUnits': 500
    },
    Tags=[
        {
            'Key': 'Title',
            'Value': 'ProductManager'
        },
    ],
)
```

Without ABAC

If ABAC isn't enabled for your AWS account, DynamoDB doesn't send the tag keys in the `create-table` command to IAM. The `Null` condition ensures that the condition evaluates to `false` if

there are no tag keys in the request. Because the Deny policy doesn't match, the `create-table` command completes successfully.

With ABAC

If ABAC is enabled for your AWS account, the tag keys passed in the `create-table` command are passed to IAM. The tag key `Title` is evaluated against the condition-based tag key, `CostCenter`, present in the Deny policy. The tag key `Title` doesn't match the tag key present in the Deny policy because of the `StringNotEquals` operator. Therefore, the `CreateTable` action fails and your table isn't created. Running the `create-table` command returns an `AccessDeniedException`.

```
An error occurred (AccessDeniedException) when calling the CreateTable operation:
 User: arn:aws:sts::123456789012:assumed-role/DynamoFullAccessRole/ProductManager is
 not authorized to perform: dynamodb:CreateTable on resource: arn:aws:dynamodb:us-
east-1:123456789012:table/myMusicTable with an explicit deny in an identity-based
 policy.
```

Troubleshooting common ABAC errors for DynamoDB tables and indexes

This topic provides troubleshooting advice for common errors and issues that you might encounter while implementing ABAC in DynamoDB tables or indexes.

Service-specific condition keys in policies result in an error

Service-specific condition keys aren't considered as valid condition keys. If you've used such keys in your policies, these will result in an error. To fix this issue, you must replace the service-specific condition keys with an appropriate condition key to implement ABAC in DynamoDB.

For example, say that you've used the `dynamodb:ResourceTag` condition key in an inline policy that performs the PutItem request. Imagine that the request fails with an `AccessDeniedException`. The following example shows the erroneous inline policy with the `dynamodb:ResourceTag` condition key.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

```
            "Action": [
                "dynamodb:PutItem"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*",
            "Condition": {
                "StringEquals": {
                    "dynamodb:ResourceTag/Owner": "John"
                }
            }
        }
    ]
}
```

To fix this issue, replace the `dynamodb:ResourceTag` condition key with `aws:ResourceTag`, as shown in the following example.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:PutItem"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/Owner": "John"
                }
            }
        }
    ]
}
```

Unable to opt out of ABAC

If ABAC was enabled for your account through Support, you won't be able to opt out of ABAC through the DynamoDB console. To opt out, contact Support.

You can opt out of ABAC yourself *only if* the following are true:

- You used the self-service way of opting in through the DynamoDB console.
- You're opting out within seven calendar days of opting in.

Using attribute-based access control with DynamoDB Streams

DynamoDB Streams supports attribute-based access control (ABAC), the same authorization strategy described in Using resource-based policies for DynamoDB. With DynamoDB Streams ABAC, you attach tags to your streams and use tag-based conditions in your IAM policies to control access to them.

Stream resources do not inherit tags from their parent table, and you can manage tags on streams independently. You can add up to 50 tags for each DynamoDB stream. The maximum size supported for all the tags on a stream is 10 KB. For more information about tagging DynamoDB resources and tagging restrictions, see Adding tags and labels to resources in DynamoDB and Tagging restrictions in DynamoDB.

You can use the aws:ResourceTag condition key to allow or deny access to a stream based on the tags that are attached to that stream. For example, the following policy allows the `GetRecords` action on any stream that includes the tag key `environment` with the value `production`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetRecords"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*/stream/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/environment": "production"
        }
      }
    }
  ]
}
```

Condition keys to implement ABAC with DynamoDB Streams

DynamoDB Streams ABAC uses the same condition keys as DynamoDB tables: `aws:ResourceTag/tag-key`, `aws:RequestTag/tag-key`, and `aws:TagKeys`. For a description of each condition key, see Condition keys to implement ABAC with DynamoDB. The following behavior is specific to DynamoDB Streams:

- The condition keys apply to the DynamoDB Streams APIs that operate on a stream, including TagResource, `UntagResource`, and read APIs such as `GetRecords`.
- When DynamoDB Streams ABAC is not enabled for your account, `aws:ResourceTag` conditions are evaluated as if no tags are attached to the stream resource.

Considerations for using ABAC with DynamoDB Streams

When you use ABAC with DynamoDB Streams, the following considerations apply:

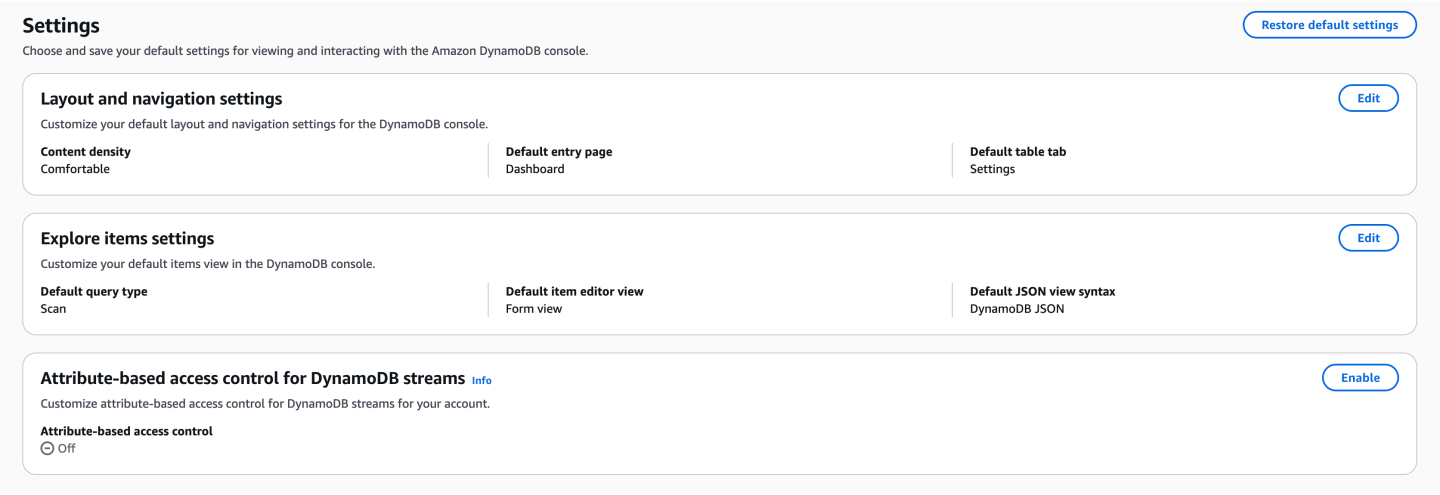
- ABAC for DynamoDB Streams is separate from ABAC for DynamoDB tables. Enabling ABAC for tables does not automatically enable it for streams in your account. You must enable each independently.
- You can tag or untag a stream after its parent table is deleted, using the CLI or SDK `tag-resource`, `untag-resource`, and `list-tags-of-resource` commands on the stream ARN. The stream continues to exist for 24 hours after table deletion before being removed. This capability is not available through the Console or CloudFormation after table deletion.
- If you use CloudFormation to manage your DynamoDB resources, make sure your service role has `dynamodb:TagResource`, `dynamodb:UntagResource` and `dynamodb:ListTagsOfResource` permissions for stream resources.

Enabling ABAC for DynamoDB Streams

DynamoDB Streams ABAC is enabled by default for most AWS accounts. For existing customers, Streams ABAC is disabled by default, and you enable it after you audit your policies. Using the DynamoDB console, you can confirm whether Streams ABAC is enabled for your account. Open the DynamoDB console using a role that has the `dynamodb:GetAbacStatus` permission. Then, open the **Settings** page of the DynamoDB console.

The **Attribute-based access control for Streams** card appears on the **Settings** page only if you have a DynamoDB table in the current AWS Region. If you have a table, a status of **On** (or no card) means Streams ABAC is enabled, and **Off** (shown in the following image) means it isn't. Without a table in the Region, the card's absence doesn't indicate the status.

Attribute-based access control for Streams – not enabled



To enable Streams ABAC for your account, we recommend that you first audit your policies as described in the Auditing your policies before enabling Streams ABAC section. Then, include the required permissions for Streams ABAC in your IAM policy. Finally, perform the steps described in Enabling Streams ABAC in console to enable Streams ABAC for your account in the current AWS Region. After you enable Streams ABAC, you can opt out within the next seven calendar days of opting in.

Topics

- Auditing your policies before enabling Streams ABAC
- IAM permissions required to enable Streams ABAC
- Enabling Streams ABAC in console

Auditing your policies before enabling Streams ABAC

Before you enable Streams ABAC, audit your policies. Confirm that any tag-based conditions in your account policies are set up as intended for stream resources. Auditing your policies helps you avoid unexpected authorization changes in your DynamoDB Streams workflows after you enable Streams ABAC.

When auditing, look for policies that:

- Use `aws:ResourceTag` conditions on stream ARNs (format: `arn:aws:dynamodb:*:*:table/*/stream/*`)
- Use `aws:RequestTag` or `aws:TagKeys` conditions with `dynamodb:TagResource` or `dynamodb:UntagResource` actions on stream resources
- Use wildcard resource ARNs (`arn:aws:dynamodb:*:*:*`) with tag-based conditions that might unintentionally apply to streams

To view examples of using attribute-based conditions with tags, and the before and after behavior of ABAC implementation, see Examples for using ABAC with DynamoDB Streams.

IAM permissions required to enable Streams ABAC

You need the `dynamodb:UpdateAbacStatus` permission to enable Streams ABAC for your account in the current Region. To confirm whether Streams ABAC is enabled for your account, you must also have the `dynamodb:GetAbacStatus` permission. With this permission, you can view the Streams ABAC status for an account in any Region. You need these permissions in addition to the permission needed for accessing the DynamoDB console.

The following IAM policy grants the permission to enable Streams ABAC and view its status for an account in the current Region.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:UpdateAbacStatus",
        "dynamodb:GetAbacStatus"
      ],
```

```
      "Resource": "*"
    }
  ]
}
```

Enabling Streams ABAC in console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. From the top navigation pane, choose the Region for which you want to enable Streams ABAC.
3. On the left navigation pane, choose **Settings**.
4. On the **Settings** page, do the following:

   a. In the **Attribute-based access control for Streams** card, choose **Enable**.

   b. In the **Confirm attribute-based access control for Streams setting** box, choose **Enable** to confirm your choice.

   This enables Streams ABAC for the current Region and the **Attribute-based access control for Streams** card shows the status of **On**.

   If you want to opt out after enabling Streams ABAC on the console, you can do so within the next seven calendar days of opting in. To opt out, choose **Disable** in the **Attribute-based access control for Streams** card on the **Settings** page.

   > **Note**
   >
   > Updating the status of Streams ABAC is an asynchronous operation. If DynamoDB doesn't evaluate the tags in your policies right away, wait a few minutes and try again. Tag evaluation changes are eventually consistent.

Using ABAC with DynamoDB Streams

The following steps show how to set up permissions using ABAC for DynamoDB Streams. In this example scenario, you add tags to a DynamoDB stream and create an IAM role with a policy that includes tag-based conditions. Then, you test the allowed permissions on the DynamoDB stream by matching the tag conditions.

Topics

- Step 1: Add tags to a DynamoDB stream
- Step 2: Create an IAM role with a policy including tag-based conditions
- Step 3: Test allowed permissions

Step 1: Add tags to a DynamoDB stream

You can add tags to DynamoDB Streams using the AWS CLI or SDK. The following `tag-resource` CLI command adds a tag to a stream.

```
aws dynamodb tag-resource \
  --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/MusicTable/
stream/2024-01-01T00:00:00.000 \
  --tags Key=environment,Value=staging
```

> **Note**
>
> To find your stream ARN, use the `describe-table` command and look for the `LatestStreamArn` field in the response.

Step 2: Create an IAM role with a policy including tag-based conditions

Create an IAM policy using the `aws:ResourceTag/{{tag-key}}` condition key to compare the tag key-value pair that's specified in the IAM policy with the key-value pair that's attached to the stream. The following example policy allows users to get records and describe a stream if the stream contains the tag key-value pair: `"environment": "staging"`. If a stream doesn't have the specified tag key-value pair, these actions are denied.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeStream",
        "dynamodb:GetRecords",
        "dynamodb:GetShardIterator"
      ],
```

```
      "Resource": "arn:aws:dynamodb:*:*:table/*/stream/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/environment": "staging"
        }
      }
    }
  ]
}
```

Step 3: Test allowed permissions

1. Attach the IAM policy to a test user or role in your AWS account. Make sure that the IAM principal you use doesn't already have access to the DynamoDB stream through a different policy.
2. Make sure that your DynamoDB stream contains the `"environment"` tag key with a value of `"staging"`.
3. Perform the `dynamodb:DescribeStream` and `dynamodb:GetRecords` actions on the tagged stream. These actions succeed if the `"environment": "staging"` tag key-value pair is present.

   If you perform these actions on a stream that doesn't have the `"environment": "staging"` tag key-value pair, your request fails with an `AccessDeniedException`.

Examples for using ABAC with DynamoDB Streams

The following examples depict use cases for implementing attribute-based conditions using tags with DynamoDB Streams.

Topics

- Example 1: Allow stream read access using aws:ResourceTag
- Example 2: Allow tagging a stream using aws:RequestTag
- Example 3: Deny stream access unless a specific tag is present
- Example 4: Tagging streams using CloudFormation

Example 1: Allow stream read access using aws:ResourceTag

Using the `aws:ResourceTag/tag-key` condition key, you can compare the tag key-value pair specified in an IAM policy with the key-value pair attached to a DynamoDB stream. For example, you can allow stream `GetRecords` operations if the tag conditions match.

Using the AWS CLI

1. Create a table with a stream enabled and add a tag.

```
aws dynamodb create-table \
  --table-name myMusicTable \
  --attribute-definitions AttributeName=id,AttributeType=S \
  --key-schema AttributeName=id,KeyType=HASH \
  --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
  --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
  --region us-east-1
```

2. Add a tag to the stream. First, get the stream ARN from the table description.

```
STREAM_ARN=$(aws dynamodb describe-table \
  --table-name myMusicTable \
  --query "Table.LatestStreamArn" \
  --output text \
  --region us-east-1)

aws dynamodb tag-resource \
  --resource-arn $STREAM_ARN \
  --tags Key=Team,Value=Analytics \
  --region us-east-1
```

3. Create an inline policy and add it to a role, as shown in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeStream",
        "dynamodb:GetRecords"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*/stream/*",
```

```
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Team": "Analytics"
        }
      }
    }
  ]
}
```

This policy allows the `DescribeStream` and `GetRecords` operations when the stream's tag matches the key "Team" and value "Analytics" specified in the policy.

4. Assume the role with the policy described in Step 3.
5. Use the `describe-stream` AWS CLI command on the stream.

```
aws dynamodb describe-stream \
  --stream-arn $STREAM_ARN \
  --region us-east-1
```

Behavior with and without Streams ABAC

Without Streams ABAC

If Streams ABAC isn't enabled for your AWS account, the tag conditions in the IAM policy and the DynamoDB stream aren't matched. The `DescribeStream` action returns an `AccessDeniedException` because no policy allows the action without matching tag conditions.

With Streams ABAC

If Streams ABAC is enabled for your AWS account, the `DescribeStream` action completes successfully. This is because the inline policy allows the action when the tag conditions in the IAM policy and the stream match.

Example 2: Allow tagging a stream using aws:RequestTag

Using the `aws:RequestTag/tag-key` condition key, you can compare the tag key-value pair that's passed in your request with the tag pair specified in the IAM policy. For example, you can allow tagging a stream only if the request includes a specific tag.

Using the AWS CLI

1. Create an inline policy and add it to a role, as shown in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:TagResource"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*/stream/*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/CostCenter": "12345"
        }
      }
    }
  ]
}
```

2. Tag the stream with the required tag key-value pair.

```
aws dynamodb tag-resource \
  --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/myMusicTable/
stream/2024-01-01T00:00:00.000 \
  --tags Key=CostCenter,Value=12345
```

Behavior with and without Streams ABAC

Without Streams ABAC

If Streams ABAC isn't enabled for your AWS account, the tag conditions in the inline policy and the request aren't matched. The `TagResource` action returns an `AccessDeniedException`.

With Streams ABAC

If Streams ABAC is enabled for your AWS account, the tag request completes successfully. Because the tag key-value pair of `"CostCenter": "12345"` is present in the `TagResource` request, the inline policy allows the action.

Example 3: Deny stream access unless a specific tag is present

Using the `aws:TagKeys` condition key, you can deny tagging a stream unless a required tag key is included in the request.

Using the AWS CLI

1. Add a customer managed policy to a role which has DynamoDB access, as shown in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "dynamodb:TagResource"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*/stream/*",
      "Condition": {
        "Null": {
          "aws:TagKeys": "false"
        },
        "ForAllValues:StringNotEquals": {
          "aws:TagKeys": "CostCenter"
        }
      }
    }
  ]
}
```

2. Assume the role and attempt to tag a stream with a tag key that is not `CostCenter`.

```
aws dynamodb tag-resource \
  --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/myMusicTable/
stream/2024-01-01T00:00:00.000 \
  --tags Key=Department,Value=Engineering
```

Behavior with and without Streams ABAC

Without Streams ABAC

If Streams ABAC isn't enabled for your AWS account, DynamoDB doesn't send the tag keys in the request to IAM. The `Null` condition ensures that the condition evaluates to false if there are no tag keys in the request. Because the Deny policy doesn't match, the `tag-resource` command completes successfully.

With Streams ABAC

If Streams ABAC is enabled for your AWS account, the tag key `Department` is evaluated against the condition-based tag key `CostCenter` present in the Deny policy. The tag key `Department` doesn't match the tag key present in the Deny policy because of the `StringNotEquals` operator. Therefore, the `TagResource` action fails and returns an `AccessDeniedException`.

Example 4: Tagging streams using CloudFormation

You can specify tags on DynamoDB Streams directly in your CloudFormation templates. Stream tags are defined within the `StreamSpecification` property for standard tables, and within the `ReplicaStreamSpecification` property for global tables.

AWS::DynamoDB::Table

```
Resources:
  MyTable:
    Type: AWS::DynamoDB::Table
    Properties:
      TableName: MyTable
      AttributeDefinitions:
        - AttributeName: id
          AttributeType: S
      KeySchema:
        - AttributeName: id
          KeyType: HASH
      BillingMode: PAY_PER_REQUEST
      Tags:
        - Key: TableEnv
          Value: Production
      StreamSpecification:
        StreamViewType: NEW_AND_OLD_IMAGES
        Tags:
```

```
          - Key: StreamEnv
            Value: Production
          - Key: StreamTeam
            Value: Payments
```

AWS::DynamoDB::GlobalTable

```
Resources:
  MyGlobalTable:
    Type: AWS::DynamoDB::GlobalTable
    Properties:
      TableName: MyGlobalTable
      AttributeDefinitions:
        - AttributeName: id
          AttributeType: S
      KeySchema:
        - AttributeName: id
          KeyType: HASH
      BillingMode: PAY_PER_REQUEST
      StreamSpecification:
        StreamViewType: NEW_AND_OLD_IMAGES
      Replicas:
        - Region: us-east-1
          Tags:
            - Key: TableEnv
              Value: Production
          ReplicaStreamSpecification:
            Tags:
              - Key: StreamEnv
                Value: Production
              - Key: StreamTeam
                Value: Payments
        - Region: eu-west-1
          Tags:
            - Key: TableEnv
              Value: Production
          ReplicaStreamSpecification:
            Tags:
              - Key: StreamEnv
                Value: Production
              - Key: StreamTeam
                Value: Payments
```

In addition to explicit stream tags, CloudFormation also propagates stack-level tags to streams. If your stack has tags configured, those tags are automatically applied to all resources in the stack, including streams.

> **Important**
>
> The IAM role used for your CloudFormation deployment must have `dynamodb:TagResource` and `dynamodb:UntagResource` permissions on stream resources (`arn:aws:dynamodb:*:*:table/*/stream/*`) to apply tags to streams. If these permissions are missing, see CloudFormation deployments fail when tagging streams for details.

Troubleshooting common ABAC errors for DynamoDB Streams

If you receive an `AccessDeniedException` or your tag-based conditions don't behave as expected after you enable ABAC for DynamoDB Streams, use this topic to diagnose and resolve the most common causes.

Service-specific condition keys in policies result in an error

Service-specific condition keys aren't considered as valid condition keys. If you've used such keys in your policies, these keys result in an error. You must replace the service-specific condition keys with an appropriate condition key to implement ABAC for DynamoDB Streams.

For example, say that you've used the `dynamodb:ResourceTag` condition key in a policy that performs the `GetRecords` request on a stream. The request fails with an `AccessDeniedException`. The following example shows the erroneous policy with the `dynamodb:ResourceTag` condition key.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetRecords"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*/stream/*",
      "Condition": {
```

```
        "StringEquals": {
          "dynamodb:ResourceTag/Team": "Analytics"
        }
      }
    }
  ]
}
```

To fix this issue, replace the `dynamodb:ResourceTag` condition key with `aws:ResourceTag`, as shown in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetRecords"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*/stream/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Team": "Analytics"
        }
      }
    }
  ]
}
```

Streams ABAC is enabled but tag conditions are not evaluated

If you recently enabled Streams ABAC, the change might not have propagated yet. Updating the status of Streams ABAC is an asynchronous operation. Wait a few minutes and retry your request.

Unable to tag a stream after parent table is deleted

After a parent table is deleted, the stream continues to exist for 24 hours before being removed. During this 24-hour window, you can manage stream tags using the CLI or SDK commands (`tag-resource`, `untag-resource`, and `list-tags-of-resource`) with the stream ARN. You can't use the console or CloudFormation to modify tags on a stream whose parent table no longer exists.

If you receive an error when attempting to tag through the console, use the CLI instead:

```
aws dynamodb tag-resource \
  --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/DeletedTable/
stream/2024-01-01T00:00:00.000 \
  --tags Key=environment,Value=production
```

To verify existing tags on the stream with parent table deleted:

```
aws dynamodb list-tags-of-resource \
  --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/DeletedTable/
stream/2024-01-01T00:00:00.000
```

If you receive a `ResourceNotFoundException`, the 24-hour retention period has expired and the stream no longer exists.

Unable to opt out of Streams ABAC

You can opt out of Streams ABAC yourself only if the following are true:

- You used the self-service way of opting in through the DynamoDB console.
- You're opting out within seven calendar days of opting in.

If Streams ABAC was enabled for your account through Support, you won't be able to opt out through the DynamoDB console. To opt out, contact Support.

CloudFormation deployments fail when tagging streams

CloudFormation deployments that create or update a table with a stream might fail if the IAM role is missing required permissions. Specifically, the role must have `dynamodb:TagResource` and `dynamodb:UntagResource` permissions for stream resources. This applies to both `AWS::DynamoDB::Table` and `AWS::DynamoDB::GlobalTable` resource types, and affects both explicit stream tags and inherited stack-level tags.

To resolve this, update your CloudFormation service role's IAM policy to include stream tagging permissions:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
      "Effect": "Allow",
      "Action": [
        "dynamodb:TagResource",
        "dynamodb:UntagResource"
      ],
      "Resource": [
        "arn:aws:dynamodb:*:*:table/*/stream/*"
      ]
    }
  ]
}
```

Data protection in DynamoDB

Amazon DynamoDB provides a highly durable storage infrastructure designed for mission-critical and primary data storage. Data is redundantly stored on multiple devices across multiple facilities in an Amazon DynamoDB Region.

DynamoDB protects user data stored at rest and also data in transit between on-premises clients and DynamoDB, and between DynamoDB and other AWS resources within the same AWS Region.

Avoid sensitive data in resource names

We strongly recommend that you never put sensitive identifying information, such as your customers' account numbers, into free-form fields such as a *Name* field, including DynamoDB table names and DynamoDB Accelerator (DAX) cluster names. This guidance applies when you work with DynamoDB or other AWS services using the console, API, AWS CLI, or AWS SDKs. Diagnostic logs might capture information that you enter into free-form fields, and for DAX clusters that use encryption in transit, public Certificate Transparency (CT) logs also record the cluster name. For more information, see DAX access control. When you provide a URL to an external server, don't include credentials in the URL that validate your request to that server.

Topics

- DynamoDB encryption at rest
- Securing DynamoDB connections using VPC endpoints and IAM policies"

DynamoDB encryption at rest

All user data stored in Amazon DynamoDB is fully encrypted at rest. DynamoDB encryption at rest provides enhanced security by encrypting all your data at rest using encryption keys stored in AWS Key Management Service (AWS KMS). This functionality helps reduce the operational burden and complexity involved in protecting sensitive data. With encryption at rest, you can build security-sensitive applications that meet strict encryption compliance and regulatory requirements.

DynamoDB encryption at rest provides an additional layer of data protection by always securing your data in an encrypted table—including its primary key, local and global secondary indexes, streams, global tables, backups, and DynamoDB Accelerator (DAX) clusters whenever the data is stored in durable media. Organizational policies, industry or government regulations, and compliance requirements often require the use of encryption at rest to increase the data security of your applications. For more information about encryption for database applications, see AWS Database Encryption SDK.

Encryption at rest integrates with AWS KMS for managing the encryption keys that are used to encrypt your tables. For more information about key types and states, see AWS Key Management Service concepts in the *AWS Key Management Service Developer Guide*.

When creating a new table, you can choose one of the following AWS KMS key types to encrypt your table. You can switch between these key types at any time.

- **AWS owned key –** Default encryption type. The key is owned by DynamoDB (no additional charge).
- **AWS managed key –** The key is stored in your account and is managed by AWS KMS (AWS KMS charges apply).
- **Customer managed key –** The key is stored in your account and is created, owned, and managed by you. You have full control over the KMS key (AWS KMS charges apply).

For more information about key types, see Customer keys and AWS keys.

Note

- When creating a new DAX cluster with encryption at rest enabled, an AWS managed key will be used to encrypt data at rest in the cluster.

- If your table has a sort key, some of the sort keys that mark range boundaries are stored in plaintext in the table metadata.

When you access an encrypted table, DynamoDB decrypts the table data transparently. You don't have to change any code or applications to use or manage encrypted tables. DynamoDB continues to deliver the same single-digit millisecond latency that you have come to expect, and all DynamoDB queries work seamlessly on your encrypted data.

You can specify an encryption key when you create a new table or switch the encryption keys on an existing table by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or the Amazon DynamoDB API. To learn how, see Managing encrypted tables in DynamoDB.

Encryption at rest using the AWS owned key is offered at no additional charge. However, AWS KMS charges apply for an AWS managed key and for a customer managed key. For more information about pricing, see AWS KMS pricing.

DynamoDB encryption at rest is available in all AWS Regions, including the AWS China (Beijing) and AWS China (Ningxia) Regions and the AWS GovCloud (US) Regions. For more information, see DynamoDB encryption at rest: How it works and DynamoDB encryption at rest usage notes.

DynamoDB encryption at rest: How it works

Amazon DynamoDB encryption at rest encrypts your data using 256-bit Advanced Encryption Standard (AES-256), which helps secure your data from unauthorized access to the underlying storage.

Encryption at rest integrates with AWS Key Management Service (AWS KMS) for managing the encryption keys that are used to encrypt your tables.

Note

In May 2022, AWS KMS changed the rotation schedule for AWS managed keys from every three years (approximately 1,095 days) to every year (approximately 365 days).
New AWS managed keys are automatically rotated one year after they are created, and approximately every year thereafter.
Existing AWS managed keys are automatically rotated one year after their most recent rotation, and every year thereafter.

AWS owned keys

AWS owned keys are not stored in your AWS account. They are part of a collection of KMS keys that AWS owns and manages for use in multiple AWS accounts. AWS services can use AWS owned keys to protect your data. AWS owned keys used by DynamoDB are rotated every year (approximately 365 days).

You cannot view, manage, or use AWS owned keys, or audit their use. However, you do not need to do any work or change any programs to protect the keys that encrypt your data.

You are not charged a monthly fee or a usage fee for use of AWS owned keys, and they do not count against AWS KMS quotas for your account.

AWS managed keys

AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. You can view the AWS managed keys in your account, view their key policies, and audit their use in AWS CloudTrail logs. However, you cannot manage these KMS keys or change their permissions.

Encryption at rest automatically integrates with AWS KMS for managing the AWS managed keys for DynamoDB (`aws/dynamodb`) that are used to encrypt your tables. If an AWS managed key doesn't exist when you create your encrypted DynamoDB table, AWS KMS automatically creates a new key for you. This key is used with encrypted tables that are created in the future. AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud.

For more information about managing permissions of the AWS managed key, see Authorizing use of the AWS managed key in the *AWS Key Management Service Developer Guide*.

Customer managed keys

Customer managed keys are KMS keys in your AWS account that you create, own, and manage. You have full control over these KMS keys, including establishing and maintaining their key policies, IAM policies, and grants; enabling and disabling them; rotating their cryptographic material; adding tags; creating aliases that refer to them; and scheduling them for deletion. For more information about managing permissions of a customer managed key, see Customer managed keys.

When you specify a customer managed key as the table-level encryption key, the DynamoDB table, local and global secondary indexes, and streams are encrypted with the same customer managed

key. On-demand backups are encrypted with the table-level encryption key that is specified at the time the backup is created. Updating the table-level encryption key does not change the encryption key that is associated with existing on-demand backups.

Setting the state of the customer managed key to disabled or scheduling it for deletion prevents all users and the DynamoDB service from being able to encrypt or decrypt data and to perform read and write operations on the table. DynamoDB must have access to your encryption key to make sure that you can continue to access your table and to prevent data loss.

If you disable your customer managed key or schedule it for deletion, your table status becomes **Inaccessible**. To make sure that you can continue working with the table, you must provide DynamoDB access to the specified encryption key within seven days. As soon as the service detects that your encryption key is inaccessible, DynamoDB sends you an email notification to alert you.

Note

- If your customer managed key remains inaccessible to the DynamoDB service for longer than seven days, the table is archived and can no longer be accessed. DynamoDB creates an on-demand backup of your table, and you are billed for it. You can use this on-demand backup to restore your data to a new table. To initiate the restore, the last customer managed key on the table must be enabled, and DynamoDB must have access to it.
- If your customer managed key that was used to encrypt a global table replica is inaccessible DynamoDB will remove this replica from the replication group. The replica will not be deleted and replication will stop from and to this region, 20 hours after detecting the customer managed key as inaccessible.

For more information, see enabling keys and deleting keys.

Notes on using AWS managed keys

Amazon DynamoDB can't read your table data unless it has access to the KMS key stored in your AWS KMS account. DynamoDB uses envelope encryption and key hierarchy to encrypt data. Your AWS KMS encryption key is used to encrypt the root key of this key hierarchy. For more information, see Envelope encryption in the *AWS Key Management Service Developer Guide*.

DynamoDB doesn't call AWS KMS for every DynamoDB operation. The key is refreshed once every 5 minutes per caller with active traffic.

Make sure that you have configured the SDK to reuse connections. Otherwise, you will experience latencies from DynamoDB having to reestablish new AWS KMS cache entries for each DynamoDB operation. In addition, you might potentially have to face higher AWS KMS and CloudTrail costs. For example, to do this using the Node.js SDK, you can create a new HTTPS agent with `keepAlive` turned on. For more information, see Configuring keepAlive in Node.js in the *AWS SDK for JavaScript Developer Guide*.

DynamoDB encryption at rest usage notes

Consider the following when you are using encryption at rest in Amazon DynamoDB.

All table data is encrypted

Server-side encryption at rest is enabled on all DynamoDB table data and cannot be disabled. You cannot encrypt only a subset of items in a table.

Encryption at rest only encrypts data while it is static (at rest) on a persistent storage media. If data security is a concern for data in transit or data in use, you might need to take additional measures:

- Data in transit: All your data in DynamoDB is encrypted in transit. By default, communications to and from DynamoDB use the HTTPS protocol, which protects network traffic by using Secure Sockets Layer (SSL)/Transport Layer Security (TLS) encryption.
- Data in use: Protect your data before sending it to DynamoDB using client-side encryption. For more information, see Client-side and server-side encryption in the *Amazon DynamoDB Encryption Client Developer Guide*.

You can use streams with encrypted tables. DynamoDB streams are always encrypted with a table-level encryption key. For more information, see Change data capture for DynamoDB Streams.

DynamoDB backups are encrypted, and the table that is restored from a backup also has encryption enabled. You can use the AWS owned key, AWS managed key, or customer managed key to encrypt your backup data. For more information, see Backup and restore for DynamoDB.

Local secondary indexes and global secondary indexes are encrypted using the same key as the base table.

Encryption types

> **Note**
>
> Customer managed keys are not supported in Global Table Version 2017. If you want to use a customer managed key in a DynamoDB Global Table, you need to upgrade the table to Global Table Version 2019 and then enable it.

On the AWS Management Console, the encryption type is `KMS` when you use the AWS managed key or customer managed key to encrypt your data. The encryption type is `DEFAULT` when you use the AWS owned key. In the Amazon DynamoDB API, the encryption type is `KMS` when you use the AWS managed key or customer managed key. In the absence of encryption type, your data is encrypted using the AWS owned key. You can switch between the AWS owned key, AWS managed key, and customer managed key at any given time. You can use the console, the AWS Command Line Interface (AWS CLI), or the Amazon DynamoDB API to switch the encryption keys.

Note the following limitations when using customer managed keys:

- You cannot use a customer managed key with DynamoDB Accelerator (DAX) clusters. For more information, see DAX encryption at rest.
- You can use a customer managed key to encrypt tables that use transactions. However, to achieve durability for propagation of transactions, a copy of the transaction request is temporarily stored by the service and encrypted using an AWS owned key. Committed data in your tables and secondary indexes is always encrypted at rest using your customer managed key.
- You can use a customer managed key to encrypt tables that use Contributor Insights. However, data that is transmitted to Amazon CloudWatch is encrypted with an AWS owned key.
- When you transition to a new customer managed key, be sure to keep the original key enabled until the process is complete. AWS will still need the original key to decrypt the data before encrypting it with the new key. The process will be complete when the table's SSEDescription Status is ENABLED and the KMSMasterKeyArn of the new customer managed key is displayed. At this point the original key can be disabled or scheduled for deletion.
- After the new customer managed key is displayed, the table and any new on-demand backups are encrypted with the new key.
- Any existing on-demand backups remain encrypted with the customer managed key that was used when those backups were created. You will need that same key to restore those

backups. You can identify the key for the period when each backup was created by using the DescribeBackup API to view that backup's SSEDescription.

- If you disable your customer managed key or schedule it for deletion, any data in DynamoDB Streams is still subject to a 24-hour lifetime. Any unretrieved activity data is eligible for trimming when it is older than 24 hours.
- If you disable your customer managed key or schedule it for deletion, Time to Live (TTL) deletes continue for 30 minutes. These TTL deletes continue to be emitted to DynamoDB Streams and are subject to the standard trimming/retention interval.

  For more information, see enabling keys and deleting keys.

Using KMS keys and data keys

The DynamoDB encryption at rest feature uses an AWS KMS key and a hierarchy of data keys to protect your table data. DynamoDB uses the same key hierarchy to protect DynamoDB streams, global tables, and backups when they are written to durable media.

We recommend that you plan your encryption strategy before implementing your table in DynamoDB. If you store sensitive or confidential data in DynamoDB, consider including client-side encryption in your plan. This way you can encrypt data as close as possible to its origin, and make sure that it is protected throughout its lifecycle. For more information see the DynamoDB encryption client documentation.

AWS KMS key

Encryption at rest protects your DynamoDB tables under an AWS KMS key. By default, DynamoDB uses an AWS owned key, a multi-tenant encryption key that is created and managed in a DynamoDB service account. But you can encrypt your DynamoDB tables under a customer managed key for DynamoDB (`aws/dynamodb`) in your AWS account. You can select a different KMS key for each table. The KMS key you select for a table is also used to encrypt its local and global secondary indexes, streams, and backups.

You select the KMS key for a table when you create or update the table. You can change the KMS key for a table at any time, either in the DynamoDB console or by using the UpdateTable operation. The process of switching keys is seamless and does not require downtime or degrade service.

> **Note**
>
> When you specify a KMS key by using a key alias, DynamoDB resolves the alias to the underlying KMS key ID at the time you set it and associates that KMS key with the table. If you later change the alias to point to a different KMS key, the table continues to use the originally resolved KMS key; updating the alias does not change the KMS key that protects the table. To protect the table with a different KMS key, change the table's encryption key directly in the DynamoDB console or by using the UpdateTable operation.

> **Important**
>
> DynamoDB supports only symmetric KMS keys. You cannot use an asymmetric KMS key to encrypt your DynamoDB tables.

Use a customer managed key to get the following features:

- You create and manage the KMS key, including setting the key policies, IAM policies and grants to control access to the KMS key. You can enable and disable the KMS key, enable and disable automatic key rotation, and delete the KMS key when it is no longer in use.
- You can use a customer managed key with imported key material or a customer managed key in a custom key store that you own and manage.
- You can audit the encryption and decryption of your DynamoDB table by examining the DynamoDB API calls to AWS KMS in AWS CloudTrail logs.

Use the AWS managed key if you need any of the following features:

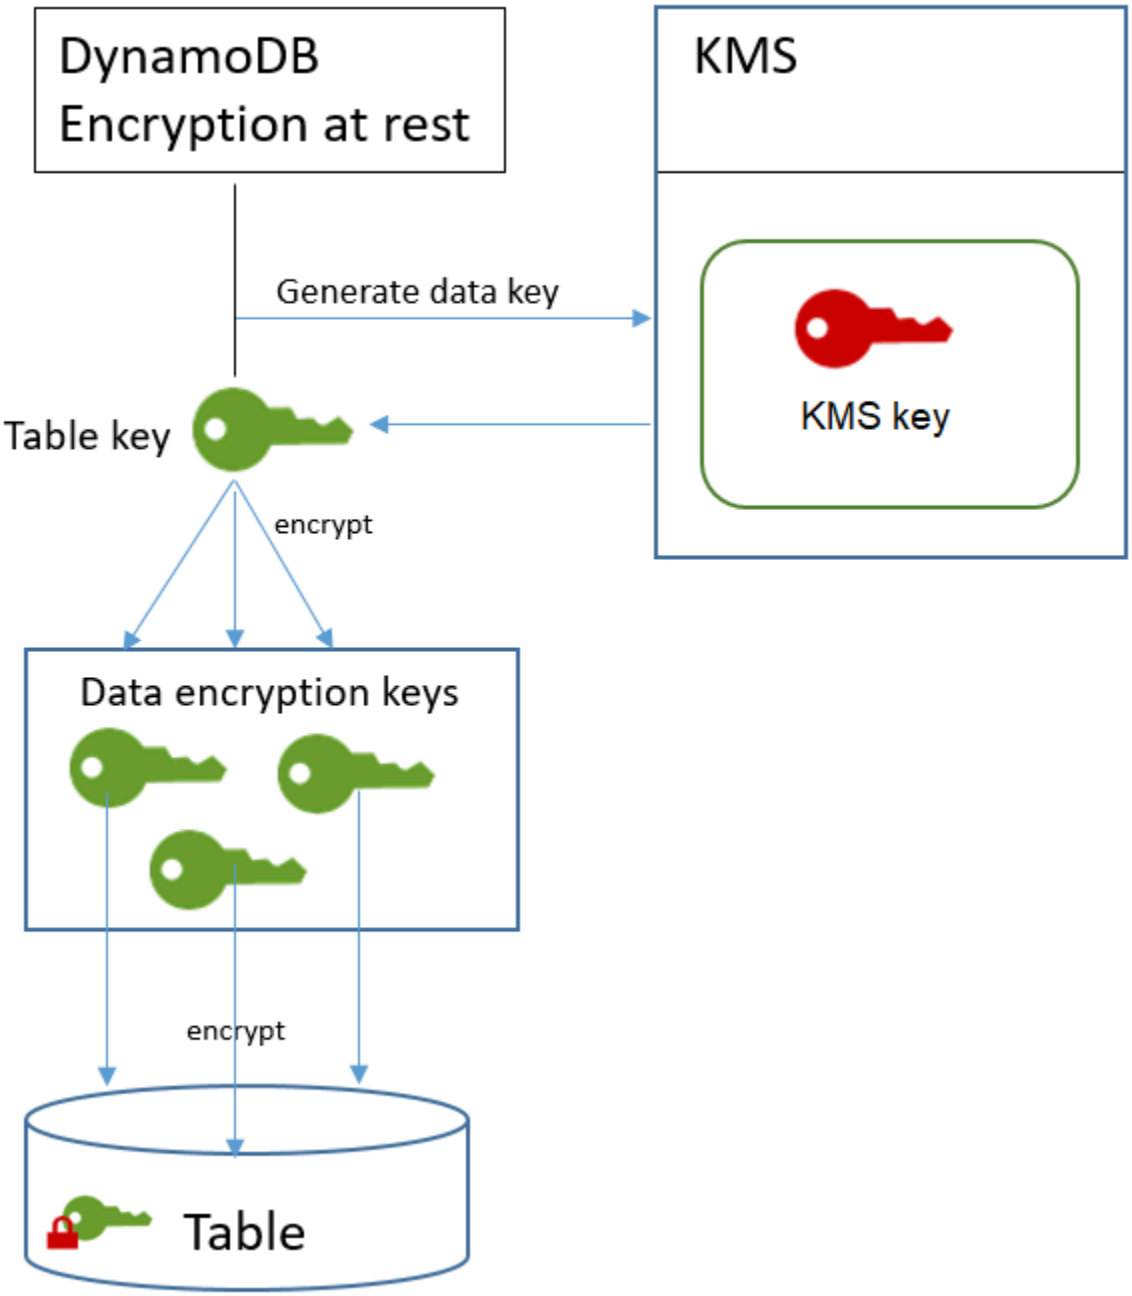
- You can view the KMS key and view its key policy. (You cannot change the key policy.)
- You can audit the encryption and decryption of your DynamoDB table by examining the DynamoDB API calls to AWS KMS in AWS CloudTrail logs.

However, the AWS owned key is free of charge and its use does not count against AWS KMS resource or request quotas. Customer managed keys and AWS managed keys incur a charge for each API call and AWS KMS quotas apply to these KMS keys.

Table keys

DynamoDB uses the KMS key for the table to generate and encrypt a unique data key for the table, known as the *table key*. The table key persists for the lifetime of the encrypted table.

The table key is used as a key encryption key. DynamoDB uses this table key to protect data encryption keys that are used to encrypt the table data. DynamoDB generates a unique data encryption key for each underlying structure in a table, but multiple table items might be protected by the same data encryption key.



When you first access an encrypted table, DynamoDB sends a request to AWS KMS to use the KMS key to decrypt the table key. Then, it uses the plaintext table key to decrypt the data encryption keys, and uses the plaintext data encryption keys to decrypt table data.

DynamoDB stores and uses the table key and data encryption keys outside of AWS KMS. It protects all keys with Advanced Encryption Standard (AES) encryption and 256-bit encryption

keys. Then, it stores the encrypted keys with the encrypted data so they are available to decrypt the table data on demand.

If you change the KMS key for your table, DynamoDB generates a new table key. Then, it uses the new table key to re-encrypt the data encryption keys.

Table key caching

To avoid calling AWS KMS for every DynamoDB operation, DynamoDB caches the plaintext table keys for each caller in memory. If DynamoDB gets a request for the cached table key after five minutes of inactivity, it sends a new request to AWS KMS to decrypt the table key. This call will capture any changes made to the access policies of the KMS key in AWS KMS or AWS Identity and Access Management (IAM) since the last request to decrypt the table key.

Authorizing use of your KMS key

If you use a customer managed key or the AWS managed key in your account to protect your DynamoDB table, the policies on that KMS key must give DynamoDB permission to use it on your behalf. The authorization context on the AWS managed key for DynamoDB includes its key policy and grants that delegate the permissions to use it.

You have full control over the policies and grants on a customer managed key Because the AWS managed key is in your account, you can view its policies and grants. But, because it is managed by AWS, you cannot change the policies.

DynamoDB does not need additional authorization to use the default AWS owned key to protect the DynamoDB tables in your AWS account.

Topics

- Key policy for an AWS managed key
- Key policy for a customer managed key
- Using grants to authorize DynamoDB

Key policy for an AWS managed key

When DynamoDB uses the AWS managed key for DynamoDB (`aws/dynamodb`) in cryptographic operations, it does so on behalf of the user who is accessing the DynamoDB resource. The key policy on the AWS managed key gives all users in the account permission to use the AWS managed key for specified operations. But permission is granted only when DynamoDB makes the request on

the user's behalf. The ViaService condition in the key policy does not allow any user to use the AWS managed key unless the request originates with the DynamoDB service.

This key policy, like the policies of all AWS managed keys, is established by AWS. You cannot change it, but you can view it at any time. For details, see Viewing a key policy.

The policy statements in the key policy have the following effect:

- Allow users in the account to use the AWS managed key for DynamoDB in cryptographic operations when the request comes from DynamoDB on their behalf. The policy also allows users to create grants for the KMS key.
- Allows authorized IAM identities in the account to view the properties of the AWS managed key for DynamoDB and to revoke the grant that allows DynamoDB to use the KMS key. DynamoDB uses grants for ongoing maintenance operations.
- Allows DynamoDB to perform read-only operations to find the AWS managed key for DynamoDB in your account.

```

Key policy for a customer managed key

When you select a customer managed key to protect a DynamoDB table, DynamoDB gets permission to use the KMS key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the KMS key that DynamoDB requires. You can provide these permissions in a key policy, an IAM policy, or a grant.

At a minimum, DynamoDB requires the following permissions on a customer managed key:

- kms:Encrypt
- kms:Decrypt
- kms:ReEncrypt* (for kms:ReEncryptFrom and kms:ReEncryptTo)
- kms:GenerateDataKey* (for kms:GenerateDataKey and kms:GenerateDataKeyWithoutPlaintext)
- kms:DescribeKey
- kms:CreateGrant

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows DynamoDB to use the KMS key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use DynamoDB. If

the principals specified in the policy statement don't have permission to use DynamoDB, the call fails, even when it comes from the DynamoDB service.

- The kms:ViaService condition key allows the permissions only when the request comes from DynamoDB on behalf of the principals listed in the policy statement. These principals can't call these operations directly. Note that the `kms:ViaService` value, `dynamodb.*.amazonaws.com`, has an asterisk (*) in the Region position. DynamoDB requires the permission to be independent of any particular AWS Region so it can make cross-Region calls to support DynamoDB global tables.
- Gives the KMS key administrators (users who can assume the `db-team` role) read-only access to the KMS key and permission to revoke grants, including the grants that DynamoDB requires to protect the table.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

    }
  ]
}
```

Using grants to authorize DynamoDB

In addition to key policies, DynamoDB uses grants to set permissions on a customer managed key or the AWS managed key for DynamoDB (`aws/dynamodb`). To view the grants on a KMS key in your account, use the ListGrants operation. DynamoDB does not need grants, or any additional permissions, to use the AWS owned key to protect your table.

DynamoDB uses the grant permissions when it performs background system maintenance and continuous data protection tasks. It also uses grants to generate table keys.

Each grant is specific to a table. If the account includes multiple tables encrypted under the same KMS key, there is a grant of each type for each table. The grant is constrained by the DynamoDB encryption context, which includes the table name and the AWS account ID, and it includes permission to the retire the grant if it is no longer needed.

To create the grants, DynamoDB must have permission to call `CreateGrant` on behalf of the user who created the encrypted table. For AWS managed keys, DynamoDB gets `kms:CreateGrant` permission from the key policy, which allows account users to call CreateGrant on the KMS key only when DynamoDB makes the request on an authorized user's behalf.

The key policy can also allow the account to revoke the grant on the KMS key. However, if you revoke the grant on an active encrypted table, DynamoDB will not be able to protect and maintain the table.

DynamoDB encryption context

An encryption context is a set of key–value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds the encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

DynamoDB uses the same encryption context in all AWS KMS cryptographic operations. If you use a customer managed key or an AWS managed key to protect your DynamoDB table, you can use the encryption context to identify use of the KMS key in audit records and logs. It also appears in plaintext in logs, such as AWS CloudTrail and Amazon CloudWatch Logs.

The encryption context can also be used as a condition for authorization in policies and grants. DynamoDB uses the encryption context to constrain the grants that allow access to the customer managed key or AWS managed key in your account and region.

In its requests to AWS KMS, DynamoDB uses an encryption context with two key–value pairs.

```
"encryptionContextSubset": {
    "aws:dynamodb:tableName": "Books"
    "aws:dynamodb:subscriberId": "111122223333"
}
```

- **Table** – The first key–value pair identifies the table that DynamoDB is encrypting. The key is `aws:dynamodb:tableName`. The value is the name of the table.

  ```
  "aws:dynamodb:tableName": "<table-name>"
  ```

  For example:

  ```
  "aws:dynamodb:tableName": "Books"
  ```

- **Account** – The second key–value pair identifies the AWS account. The key is `aws:dynamodb:subscriberId`. The value is the account ID.

  ```
  "aws:dynamodb:subscriberId": "<account-id>"
  ```

For example:

```
"aws:dynamodb:subscriberId": "111122223333"
```

Monitoring DynamoDB interaction with AWS KMS

If you use a customer managed key or an AWS managed key to protect your DynamoDB tables, you can use AWS CloudTrail logs to track the requests that DynamoDB sends to AWS KMS on your behalf.

The `GenerateDataKey`, `Decrypt`, and `CreateGrant` requests are discussed in this section. In addition, DynamoDB uses a DescribeKey operation to determine whether the KMS key you selected exists in the account and region. It also uses a RetireGrant operation to remove a grant when you delete a table.

GenerateDataKey

When you enable encryption at rest on a table, DynamoDB creates a unique table key. It sends a GenerateDataKey request to AWS KMS that specifies the KMS key for the table.

The event that records the `GenerateDataKey` operation is similar to the following example event. The user is the DynamoDB service account. The parameters include the Amazon Resource Name (ARN) of the KMS key, a key specifier that requires a 256-bit key, and the encryption context that identifies the table and the AWS account.

    "sharedEventID": "bf915fa6-6ceb-4659-8912-e36b69846aad"
}
```

Decrypt

When you access an encrypted DynamoDB table, DynamoDB needs to decrypt the table key so that it can decrypt the keys below it in the hierarchy. It then decrypts the data in the table. To decrypt the table key. DynamoDB sends a Decrypt request to AWS KMS that specifies the KMS key for the table.

The event that records the `Decrypt` operation is similar to the following example event. The user is the principal in your AWS account who is accessing the table. The parameters include the encrypted table key (as a ciphertext blob) and the encryption context that identifies the table and the AWS account. AWS KMS derives the ID of the KMS key from the ciphertext.

```
{

                "principalId": "AROAIGDT3HGFQZX4RY6RU",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "Admin"
            }
        },
        "invokedBy": "dynamodb.amazonaws.com"
    },
    "eventTime": "2018-02-14T16:42:39Z",
    "eventSource": "kms.amazonaws.com",
    "eventName": "Decrypt",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "dynamodb.amazonaws.com",
    "userAgent": "dynamodb.amazonaws.com",
    "requestParameters":
    {
        "encryptionContext":
        {
            "aws:dynamodb:tableName": "Books",
            "aws:dynamodb:subscriberId": "111122223333"
        }
    },
    "responseElements": null,
    "requestID": "11cab293-11a6-11e8-8386-13160d3e5db5",
    "eventID": "b7d16574-e887-4b5b-a064-bf92f8ec9ad3",
    "readOnly": true,
    "resources": [
        {
            "ARN": "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
            "accountId": "111122223333",
            "type": "AWS::KMS::Key"
        }
    ],
    "eventType": "AwsApiCall",
    "recipientAccountId": "111122223333"
}
```

CreateGrant

When you use a customer managed key or an AWS managed key to protect your DynamoDB table, DynamoDB uses grants to allow the service to perform continuous data protection and maintenance and durability tasks. These grants are not required on AWS owned key.

The grants that DynamoDB creates are specific to a table. The principal in the CreateGrant request is the user who created the table.

The event that records the `CreateGrant` operation is similar to the following example event. The parameters include the Amazon Resource Name (ARN) of the KMS key for the table, the grantee principal and retiring principal (the DynamoDB service), and the operations that the grant covers. It also includes a constraint that requires all encryption operation use the specified encryption context.

```
{
    "eventVersion": "1.05",
    "userIdentity":
    {
        "type": "AssumedRole",
        "principalId": "AROAIGDTESTANDEXAMPLE:user01",
        "arn": "arn:aws:sts::111122223333:assumed-role/Admin/user01",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2018-02-14T00:12:02Z"
            },
            "sessionIssuer": {

```

Managing encrypted tables in DynamoDB

You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to specify the encryption key on new tables and update the encryption keys on existing tables in Amazon DynamoDB.

Topics

- Specifying the encryption key for a new table
- Updating an encryption key

Specifying the encryption key for a new table

Follow these steps to specify the encryption key on a new table using the Amazon DynamoDB console or the AWS CLI.

Creating an encrypted table (console)

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose **Create Table**. For the **Table name**, enter **`Music`**. For the primary key, enter **`Artist`**, and for the sort key, enter **`SongTitle`**, both as strings.
4. In **Settings**, make sure that **Customize settings** is selected.

   > **Note**
   >
   > If **Use default settings** is selected, tables are encrypted at rest with the AWS owned key at no additional cost.

5. Under **Encryption at rest**, choose an encryption type - AWS owned key, AWS managed key, or customer managed key.

   - **Owned by Amazon DynamoDB.** AWS owned key, specifically owned and managed by DynamoDB. You are not charged an additional fee for using this key.
   - **AWS managed key**. Key alias: `aws/dynamodb`. The key is stored in your account and is managed by AWS Key Management Service (AWS KMS). AWS KMS charges apply.

- **Stored in your account, and owned and managed by you.** Customer managed key. The key is stored in your account and is managed by AWS Key Management Service (AWS KMS). AWS KMS charges apply.

> **Note**
>
> If you select to own and manage your own key, make sure the KMS Key Policy is appropriately set. For more information including examples, see Key policy for a customer managed key.

6. Choose **Create table** to create the encrypted table. To confirm the encryption type, select the table details on the **Overview** tab and review the **Additional details** section.

Creating an encrypted table (AWS CLI)

Use the AWS CLI to create a table with the default AWS owned key, the AWS managed key, or a customer managed key for Amazon DynamoDB.

To create an encrypted table with the default AWS owned key

- Create the encrypted `Music` table as follows.

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
      AttributeName=Artist,AttributeType=S \
      AttributeName=SongTitle,AttributeType=S \
  --key-schema \
      AttributeName=Artist,KeyType=HASH \
      AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput \
      ReadCapacityUnits=10,WriteCapacityUnits=5
```

> **Note**
>
> This table is now encrypted using the default AWS owned key in the DynamoDB service account.

To create an encrypted table with the AWS managed key for DynamoDB

- Create the encrypted `Music` table as follows.

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
      AttributeName=Artist,AttributeType=S \
      AttributeName=SongTitle,AttributeType=S \
  --key-schema \
      AttributeName=Artist,KeyType=HASH \
      AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput \
      ReadCapacityUnits=10,WriteCapacityUnits=5 \
  --sse-specification Enabled=true,SSEType=KMS
```

The `SSEDescription` status of the table description is set to `ENABLED` and the `SSEType` is `KMS`.

```
"SSEDescription": {
  "SSEType": "KMS",
  "Status": "ENABLED",
  "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-
a123-ab1234a1b234",
}
```

To create an encrypted table with a customer managed key for DynamoDB

- Create the encrypted `Music` table as follows.

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
      AttributeName=Artist,AttributeType=S \
      AttributeName=SongTitle,AttributeType=S \
  --key-schema \
      AttributeName=Artist,KeyType=HASH \
      AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput \
      ReadCapacityUnits=10,WriteCapacityUnits=5 \
```

```
  --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-
a123-ab1234a1b234
```

> **Note**
>
> For the `KMSMasterKeyId`, you can use a key ID, key ARN, or key alias. If you use a key alias (for example, `alias/my-key`), DynamoDB resolves the alias and associates the underlying AWS KMS key with the table. In the table description, the `KMSMasterKeyArn` will always show the key ARN of the resolved key, not the alias. For more information about key identifiers, see Key identifiers (KeyId) in the *AWS Key Management Service Developer Guide*.

The `SSEDescription` status of the table description is set to `ENABLED` and the `SSEType` is `KMS`.

```
"SSEDescription": {
  "SSEType": "KMS",
  "Status": "ENABLED",
  "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-
a123-ab1234a1b234",
}
```

Updating an encryption key

You can also use the DynamoDB console or the AWS CLI to update the encryption keys of an existing table between an AWS owned key, AWS managed key, and customer managed key at any time.

Updating an encryption key (console)

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the table that you want to update.
4. Select the **Actions** dropdown, and then select the **Update settings** option.
5. Go to the **Additional settings** tab.

6. Under **Encryption**, choose **Manage encryption**.
7. Choose an encryption type:

   - **Owned by Amazon DynamoDB.** The AWS KMS key is owned and managed by DynamoDB. You are not charged an additional fee for using this key.
   - **AWS managed key** Key alias: `aws/dynamodb`. The key is stored in your account and is managed by AWS Key Management Service. (AWS KMS). AWS KMS charges apply.
   - **Stored in your account, and owned and managed by you.** The key is stored in your account and is managed by AWS Key Management Service. (AWS KMS). AWS KMS charges apply.

   > **Note**
   >
   > If you select to own and manage your own key, make sure the KMS Key Policy is appropriately set. For more information see Key policy for a customer managed key.

   Then choose **Save** to update the encrypted table. To confirm the encryption type, check the table details under the **Overview** tab.

Updating an encryption key (AWS CLI)

The following examples show how to update an encrypted table using the AWS CLI.

To update an encrypted table with the default AWS owned key

- Update the encrypted `Music` table, as in the following example.

```
aws dynamodb update-table \
  --table-name Music \
  --sse-specification Enabled=false
```

> **Note**
>
> This table is now encrypted using the default AWS owned key in the DynamoDB service account.

To update an encrypted table with the AWS managed key for DynamoDB

- Update the encrypted `Music` table, as in the following example.

```
aws dynamodb update-table \
  --table-name Music \
  --sse-specification Enabled=true
```

The `SSEDescription` status of the table description is set to `ENABLED` and the `SSEType` is `KMS`.

```
"SSEDescription": {
  "SSEType": "KMS",
  "Status": "ENABLED",
  "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-
a123-ab1234a1b234",
}
```

To update an encrypted table with a customer managed key for DynamoDB

- Update the encrypted `Music` table, as in the following example.

```
aws dynamodb update-table \
  --table-name Music \
  --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-
a123-ab1234a1b234
```

> **Note**
>
> For the `KMSMasterKeyId`, you can use a key ID, key ARN, or key alias. If you use a key alias (for example, `alias/my-key`), DynamoDB resolves the alias and associates the underlying AWS KMS key with the table. In the table description, the `KMSMasterKeyArn` will always show the key ARN of the resolved key, not the alias.

The `SSEDescription` status of the table description is set to `ENABLED` and the `SSEType` is `KMS`.

```
"SSEDescription": {
  "SSEType": "KMS",
  "Status": "ENABLED",
  "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-
a123-ab1234a1b234",
}
```

Securing DynamoDB connections using VPC endpoints and IAM policies"

Connections are protected both between Amazon DynamoDB and on-premises applications and between DynamoDB and other AWS resources within the same AWS Region.

Required policy for endpoints

Amazon DynamoDB provides a DescribeEndpoints API that enables you to enumerate regional endpoint information. For requests to the public DynamoDB endpoints, the API responds regardless of the configured DynamoDB IAM policy, even if there is an explicit or implicit deny in the IAM or VPC endpoint policy. This is because DynamoDB intentionally skips authorization for the `DescribeEndpoints` API.

For requests from a VPC endpoint, both the IAM and Virtual Private Cloud (VPC) endpoint policies must authorize the `DescribeEndpoints` API call for the requesting Identity and Access Management (IAM) principal(s) using the IAM `dynamodb:DescribeEndpoints` action. Otherwise, access to the `DescribeEndpoints` API will be denied.

The following is an example of an endpoints policy.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
```

```
            },
            "Action": "dynamodb:DescribeEndpoints",
            "Resource": "*"
        }
    ]
}
```

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN? in the *AWS Site-to-Site VPN User Guide*.
- An Direct Connect connection. For more information, see What is Direct Connect? in the *Direct Connect User Guide*.

Access to DynamoDB over the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend TLS 1.3. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the AWS Security Token Service (STS) to generate temporary security credentials to sign requests.

Traffic between AWS resources in the same Region

An Amazon Virtual Private Cloud (Amazon VPC) endpoint for DynamoDB is a logical entity within a VPC that allows connectivity only to DynamoDB. The Amazon VPC routes requests to DynamoDB and routes responses back to the VPC. For more information, see VPC endpoints in the *Amazon VPC User Guide*. For example policies that you can use to control access from VPC endpoints, see Using IAM policies to control access to DynamoDB.

> **Note**
>
> Amazon VPC endpoints are not accessible through AWS Site-to-Site VPN or Direct Connect.

AWS Identity and Access Management (IAM) and DynamoDB

AWS Identity and Access Management is an AWS service that helps an administrator securely control access to AWS resources. Administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon DynamoDB and DynamoDB Accelerator resources. You can use IAM to manage access permissions and implement security policies for both Amazon DynamoDB and DynamoDB Accelerator. IAM is an AWS service that you can use with no additional charge.

Topics

- Identity and Access Management for Amazon DynamoDB
- Using IAM policy conditions for fine-grained access control

Identity and Access Management for Amazon DynamoDB

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use DynamoDB resources. IAM is an AWS service that you can use with no additional charge.

Topics

- Audience
- Authenticating with identities
- Managing access using policies
- How Amazon DynamoDB works with IAM
- Identity-based policy examples for Amazon DynamoDB
- Troubleshooting Amazon DynamoDB identity and access
- IAM policy to prevent the purchase of DynamoDB reserved capacity

Audience

How you use AWS Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see Troubleshooting Amazon DynamoDB identity and access)
- **Service administrator** - determine user access and submit permission requests (see How Amazon DynamoDB works with IAM)
- **IAM administrator** - write policies to manage access (see Identity-based policy examples for Amazon DynamoDB)

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see AWS Signature Version 4 for API requests in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see Require human users to use federation with an identity provider to access AWS using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity with specific permissions that provides temporary credentials. You can assume a role by switching from a user to an IAM role (console) or by calling an AWS CLI or AWS API operation. For more information, see Methods to assume a role in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see Choose between managed policies and inline policies in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must specify a principal in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see Service control policies in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon DynamoDB works with IAM

Before you use IAM to manage access to DynamoDB, learn what IAM features are available to use with DynamoDB.

IAM feature	DynamoDB support
Identity-based policies	Yes
Resource-based policies	Yes
Policy actions	Yes
Policy resources	Yes
Policy condition keys	Yes
ACLs	No
ABAC (tags in policies)	Yes
Temporary credentials	Yes
Principal permissions	Yes
Service roles	Yes
Service-linked roles	Yes

To get a high-level view of how DynamoDB and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

Identity-based policies for DynamoDB

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for DynamoDB

To view examples of DynamoDB identity-based policies, see Identity-based policy examples for Amazon DynamoDB.

Resource-based policies within DynamoDB

Supports resource-based policies: Yes

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for DynamoDB

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

To see a list of DynamoDB actions, see Actions defined by Amazon DynamoDB in the *Service Authorization Reference*.

Policy actions in DynamoDB use the following prefix before the action:

```
aws
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "aws:action1",
      "aws:action2"
         ]
```

To view examples of DynamoDB identity-based policies, see Identity-based policy examples for Amazon DynamoDB.

Policy resources for DynamoDB

Supports policy resources: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of DynamoDB resource types and their ARNs, see Resources defined by Amazon DynamoDB in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Amazon DynamoDB.

To view examples of DynamoDB identity-based policies, see Identity-based policy examples for Amazon DynamoDB.

Policy condition keys for DynamoDB

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

To see a list of DynamoDB condition keys, see Condition keys for Amazon DynamoDB in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon DynamoDB.

To view examples of DynamoDB identity-based policies, see Identity-based policy examples for Amazon DynamoDB.

Access control lists (ACLs) in DynamoDB

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) with DynamoDB

Supports ABAC (tags in policies): Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using Temporary credentials with DynamoDB

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

Cross-service principal permissions for DynamoDB

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

Service roles for DynamoDB

Supports service roles: Yes

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break DynamoDB functionality. Edit service roles only when DynamoDB provides guidance to do so.

Service-linked roles for DynamoDB

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing service-linked roles, see AWS services that work with IAM. Find a service in the table that includes a `Yes` in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Supported service-linked roles in DynamoDB

The following service-linked roles are supported in DynamoDB.

- DynamoDB uses the service-linked role **AWSServiceRoleForDynamoDBReplication** for global tables replication across AWS Regions. See DynamoDB global tables security for more information about the **AWSServiceRoleForDynamoDBReplication** service-linked role.
- DynamoDB Accelerator (DAX) uses the service-linked role **AWSServiceRoleForDAX** for configuring and maintaining a DAX cluster. See the section called "Using service-linked roles for DAX" for more information about the **AWSServiceRoleForDAX** service-linked role.

In addition to these DynamoDB service-linked roles, DynamoDB uses the Application Auto Scaling service for automatically managing throughput settings on provisioned capacity mode tables. The Application Auto Scaling service uses the service-linked role **AWSServiceRoleForApplicationAutoScaling_DynamoDBTable** to manage throughput settings on DynamoDB tables that have auto scaling enabled. See Service-linked roles for Application Auto Scaling for more information.

Identity-based policy examples for Amazon DynamoDB

By default, users and roles don't have permission to create or modify DynamoDB resources. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Create IAM policies (console) in the *IAM User Guide*.

For details about actions and resource types defined by DynamoDB, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon DynamoDB in the *Service Authorization Reference*.

Topics

- Policy best practices
- Using the DynamoDB console
- Allow users to view their own permissions
- Using identity-based policies with Amazon DynamoDB

Policy best practices

Identity-based policies determine whether someone can create, access, or delete DynamoDB resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the DynamoDB console

To access the Amazon DynamoDB console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the DynamoDB resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To make sure that users and roles can still use the DynamoDB console, also attach the DynamoDB `ConsoleAccess` or `ReadOnly` AWS managed policy to the entities. For more information, see Adding permissions to a user in the *IAM User Guide*.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
```

```
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Using identity-based policies with Amazon DynamoDB

This topic covers using identity-based AWS Identity and Access Management (IAM) policies with Amazon DynamoDB and provides examples. The examples show how an account administrator can attach permissions policies to IAM identities (users, groups, and roles) and thereby grant permissions to perform operations on Amazon DynamoDB resources.

The sections in this topic cover the following:

- IAM permissions required to use the Amazon DynamoDB console
- AWS managed (predefined) IAM policies for Amazon DynamoDB
- Customer managed policy examples

The following is an example of a permissions policy.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DescribeQueryScanBooksTable",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeTable",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:111122223333:table/Books"
```

```
        }
    ]
}
```

The preceding policy has one statement that grants permissions for three DynamoDB actions (`dynamodb:DescribeTable`, `dynamodb:Query`, and `dynamodb:Scan`) on a table in the `us-west-2` AWS Region, which is owned by the AWS account specified by *`account-id`*. The *Amazon Resource Name (ARN)* in the `Resource` value specifies the table that the permissions apply to.

IAM permissions required to use the Amazon DynamoDB console

To work with the DynamoDB console, a user must have a minimum set of permissions that allow the user to work with their AWS account's DynamoDB resources. In addition to these DynamoDB permissions, the console requires permissions:

- Amazon CloudWatch permissions to display metrics and graphs.
- AWS Data Pipeline permissions to export and import DynamoDB data.
- AWS Identity and Access Management permissions to access roles necessary for exports and imports.
- Amazon Simple Notification Service permissions to notify you whenever a CloudWatch alarm is triggered.
- AWS Lambda permissions to process DynamoDB Streams records.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console won't function as intended for users with that IAM policy. To make sure that those users can still use the DynamoDB console, also attach the `AmazonDynamoDBReadOnlyAccess` AWS managed policy to the user, as described in AWS managed (predefined) IAM policies for Amazon DynamoDB.

You don't need to allow minimum console permissions for users who are making calls only to the AWS CLI or the Amazon DynamoDB API.

> **Note**
>
> If you refer to a VPC endpoint, you will also need to authorize the DescribeEndpoints API call for the requesting IAM principal(s) with the IAM action (dynamodb:DescribeEndpoints). For more information see Required policy for endpoints.

AWS managed (predefined) IAM policies for Amazon DynamoDB

AWS addresses some common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate which permissions are needed. For more information, see AWS Managed Policies in the *IAM User Guide*.

The following AWS managed policies, which you can attach to users in your account, are specific to DynamoDB and are grouped by use-case scenario:

- **AmazonDynamoDBReadOnlyAccess** – Grants read-only access to DynamoDB resources through the AWS Management Console.
- **AmazonDynamoDBFullAccess** – Grants full access to DynamoDB resources through the AWS Management Console.

You can review these AWS managed permissions policies by signing in to the IAM console and searching for specific policies there.

> **Important**
>
> The best practice is to create custom IAM policies that grant least-privilege to the users, roles, or groups that require them.

Customer managed policy examples

In this section, you can find policy examples that grant permissions for various DynamoDB actions. These policies work when you use AWS SDKs or the AWS CLI. When you use the console, you need to grant additional permissions that are specific to the console. For more information, see IAM permissions required to use the Amazon DynamoDB console.

> **Note**
>
> All of the following policy examples use one of the AWS Regions and contain fictitious account IDs and table names.

Examples:

- IAM policy to grant permissions to all DynamoDB actions on a table
- IAM policy to grant read-only permissions on items in a DynamoDB table
- IAM policy to grant access to a specific DynamoDB table and its indexes
- IAM policy to read, write, update, and delete access on a DynamoDB table
- IAM policy to separate DynamoDB environments in the same AWS account
- IAM policy to prevent the purchase of DynamoDB reserved capacity
- IAM policy to grant read access for a DynamoDB stream only (not for the table)
- IAM policy to allow an AWS Lambda function to access DynamoDB stream records
- IAM policy for read and write access to a DynamoDB Accelerator (DAX) cluster
- IAM policy to grant access to search a vector index

The *IAM User Guide*, includes three additional DynamoDB examples:

- Amazon DynamoDB: Allows Access to a Specific Table
- Amazon DynamoDB: Allows Access to Specific Columns
- Amazon DynamoDB: Allows Row-Level Access to DynamoDB Based on an Amazon Cognito ID

IAM policy to grant permissions to all DynamoDB actions on a table

The following policy grants permissions for *all* DynamoDB actions on a table called `Books`. The resource ARN specified in the `Resource` identifies a table in a specific AWS Region. If you replace the table name `Books` in the `Resource` ARN with a wildcard character (*), *all* DynamoDB actions are allowed on *all* tables in the account. Carefully consider the possible security implications before using a wildcard character on this or any IAM policy.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllAPIActionsOnBooks",
            "Effect": "Allow",
            "Action": "dynamodb:*",
```

```
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

> **Note**
>
> This is an example of using a wildcard character (*) to allow *all* actions, including administration, data operations, monitoring, and purchase of DynamoDB reserved capacity. Instead, it is a best practice to explicitly specify each action to be granted and only what that user, role, or group needs.

IAM policy to grant read-only permissions on items in a DynamoDB table

The following permissions policy grants permissions for the `GetItem`, `BatchGetItem`, `Scan`, `Query`, and `ConditionCheckItem` DynamoDB actions only, and as a result, sets read-only access on the `Books` table.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ReadOnlyAPIActionsOnBooks",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

IAM policy to grant access to a specific DynamoDB table and its indexes

The following policy grants permissions for data modification actions on a DynamoDB table called Books and all of that table's indexes. For more information about how indexes work, see Improving data access with secondary indexes in DynamoDB.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AccessTableAllIndexesOnBooks",
            "Effect": "Allow",
            "Action": [
              "dynamodb:PutItem",
              "dynamodb:UpdateItem",
              "dynamodb:DeleteItem",
              "dynamodb:BatchWriteItem",
              "dynamodb:GetItem",
              "dynamodb:BatchGetItem",
              "dynamodb:Scan",
              "dynamodb:Query",
              "dynamodb:ConditionCheckItem"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books",
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*"
            ]
        }
    ]
}
```

IAM policy to read, write, update, and delete access on a DynamoDB table

Use this policy if you need to allow your application to create, read, update, and delete data in Amazon DynamoDB tables, indexes, and streams. Substitute the AWS Region name, your account ID, and the table name or wildcard character (*) where appropriate.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBIndexAndStreamAccess",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetShardIterator",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:DescribeStream",
                "dynamodb:GetRecords",
                "dynamodb:ListStreams"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*",
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/stream/*"
            ]
        },
        {
            "Sid": "DynamoDBTableAccess",
            "Effect": "Allow",
            "Action": [
                "dynamodb:BatchGetItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:ConditionCheckItem",
                "dynamodb:PutItem",
                "dynamodb:DescribeTable",
                "dynamodb:DeleteItem",
                "dynamodb:GetItem",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:UpdateItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        },
        {
            "Sid": "DynamoDBDescribeLimitsAccess",
            "Effect": "Allow",
            "Action": "dynamodb:DescribeLimits",
            "Resource": [
```

```
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books",
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*"
            ]
        }
    ]
}
```

To expand this policy to cover all DynamoDB tables in all AWS Regions for this account, use a wildcard (*) for the Region and table name. For example:

```
"Resource":[
               "arn:aws:dynamodb:*:123456789012:table/*",
               "arn:aws:dynamodb:*:123456789012:table/*/index/*"
               ]
```

IAM policy to separate DynamoDB environments in the same AWS account

Suppose that you have separate environments where each environment maintains its own version of a table named `ProductCatalog`. If you create two `ProductCatalog` tables in the same AWS account, work in one environment might affect the other environment because of the way that permissions are set up. For example, quotas on the number of concurrent control plane operations (such as `CreateTable`) are set at the AWS account level.

As a result, each action in one environment reduces the number of operations available in the other environment. There is also a risk that the code in one environment might accidentally access tables in the other environment.

> **Note**
>
> If you want to separate production and test workloads to help control an event's potential "blast radius," the best practice is to create separate AWS accounts for test and production workloads. For more information, see AWS Account Management and Separation.

Suppose further that you have two developers, Amit and Alice, who are testing the `ProductCatalog` table. Instead of each developer requiring a separate AWS account, your developers can share the same test AWS account. In this test account, you can create a copy of the same table for each developer to work on, such as `Alice_ProductCatalog` and

`Amit_ProductCatalog`. In this case, you can create users Alice and Amit in the AWS account that you created for the test environment. You then can grant permissions to these users to perform DynamoDB actions on the tables that they own.

To grant these IAM user permissions, you can do either of the following:

- Create a separate policy for each user, and then attach each policy to its user separately. For example, you can attach the following policy to user Alice to allow her access to DynamoDB actions on the `Alice_ProductCatalog` table:

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllAPIActionsOnAliceTable",
            "Effect": "Allow",
            "Action": [
              "dynamodb:DeleteItem",
              "dynamodb:DescribeContributorInsights",
              "dynamodb:RestoreTableToPointInTime",
              "dynamodb:ListTagsOfResource",
              "dynamodb:CreateTableReplica",
              "dynamodb:UpdateContributorInsights",
              "dynamodb:CreateBackup",
              "dynamodb:DeleteTable",
              "dynamodb:UpdateTableReplicaAutoScaling",
              "dynamodb:UpdateContinuousBackups",
              "dynamodb:TagResource",
              "dynamodb:DescribeTable",
              "dynamodb:GetItem",
              "dynamodb:DescribeContinuousBackups",
              "dynamodb:BatchGetItem",
              "dynamodb:UpdateTimeToLive",
              "dynamodb:BatchWriteItem",
              "dynamodb:ConditionCheckItem",
              "dynamodb:UntagResource",
              "dynamodb:PutItem",
              "dynamodb:Scan",
              "dynamodb:Query",
              "dynamodb:UpdateItem",
              "dynamodb:DeleteTableReplica",
```

```
                "dynamodb:DescribeTimeToLive",
                "dynamodb:RestoreTableFromBackup",
                "dynamodb:UpdateTable",
                "dynamodb:DescribeTableReplicaAutoScaling",
                "dynamodb:GetShardIterator",
                "dynamodb:DescribeStream",
                "dynamodb:GetRecords",
                "dynamodb:DescribeLimits",
                "dynamodb:ListStreams"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/
Alice_ProductCatalog/*"
        }
    ]
}
```

Then, you can create a similar policy with a different resource (the `Amit_ProductCatalog` table) for user Amit.

- Instead of attaching policies to individual users, you can use IAM policy variables to write a single policy and attach it to a group. You need to create a group and, for this example, add both users Alice and Amit to the group. The following example grants permissions to perform all DynamoDB actions on the `${aws:username}_ProductCatalog` table. The policy variable `${aws:username}` is replaced by the requester's user name when the policy is evaluated. For example, if Alice sends a request to add an item, the action is allowed only if Alice is adding items to the `Alice_ProductCatalog` table.

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ActionsOnUserSpecificTable",
            "Effect": "Allow",
            "Action": [
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Scan",
```

```
                "dynamodb:Query",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/
${aws:username}_ProductCatalog"
        },
        {
            "Sid": "AdditionalPrivileges",
            "Effect": "Allow",
            "Action": [
                "dynamodb:ListTables",
                "dynamodb:DescribeTable",
                "dynamodb:DescribeContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/*"
        }
    ]
}
```

Note

When using IAM policy variables, you must explicitly specify the `2012-10-17` version of the IAM policy language in the policy. The default version of the IAM policy language (`2008-10-17`) does not support policy variables.

Instead of identifying a specific table as a resource as you normally would, you could use a wildcard character (*) to grant permissions on all tables where the table name is prefixed with the user that is making the request, as shown in the following example.

```
"Resource":"arn:aws:dynamodb:us-west-2:123456789012:table/${aws:username}_*"
```

IAM policy to prevent the purchase of DynamoDB reserved capacity

With Amazon DynamoDB reserved capacity, you pay a one-time, upfront fee and commit to paying for a minimum usage level at significant savings over a period of time. You can use the AWS Management Console to view and purchase reserved capacity. However, you might not want all of the users in your organization to be able to purchase reserved capacity. For more information about reserved capacity, see Amazon DynamoDB pricing.

DynamoDB provides the following API operations for controlling access to reserved capacity management:

- `dynamodb:DescribeReservedCapacity` – Returns the reserved capacity purchases that are currently in effect.
- `dynamodb:DescribeReservedCapacityOfferings` – Returns details about the reserved capacity plans that are currently offered by AWS.
- `dynamodb:PurchaseReservedCapacityOfferings` – Performs an actual purchase of reserved capacity.

The AWS Management Console uses these API actions to display reserved capacity information and make purchases. You cannot call these operations from an application program because they can be accessed only from the console. However, you can allow or deny access to these operations in an IAM permissions policy.

The following policy allows users to view reserved capacity purchases and offerings by using the AWS Management Console — but new purchases are denied.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowReservedCapacityDescriptions",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeReservedCapacity",
                "dynamodb:DescribeReservedCapacityOfferings"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
        },
        {
            "Sid": "DenyReservedCapacityPurchases",
            "Effect": "Deny",
            "Action": "dynamodb:PurchaseReservedCapacityOfferings",
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
        }
    ]
```

```
}
```

Note that this policy uses the wildcard character (*) to allow describe permissions for all, and to deny the purchase of DynamoDB reserved capacity for all.

IAM policy to grant read access for a DynamoDB stream only (not for the table)

When you enable DynamoDB Streams on a table, information is captured about every modification to items in the table. For more information, see Change data capture for DynamoDB Streams.

In some cases, you might want to prevent an application from reading data from a DynamoDB table, but still allow access to that table's streams. For example, you can configure AWS Lambda to poll a stream and invoke a Lambda function when item updates are detected, and then perform additional processing.

The following actions are available for controlling access to DynamoDB streams:

- `dynamodb:DescribeStream`
- `dynamodb:GetRecords`
- `dynamodb:GetShardIterator`
- `dynamodb:ListStreams`

The following example policy grants users permissions to access the streams of a table named `GameScores`. The wildcard character (*) in the ARN matches any stream associated with that table.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AccessGameScoresStreamOnly",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeStream",
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator",
                "dynamodb:ListStreams"
```

```
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/stream/*"
        }
    ]
}
```

Note that this policy grants access to the `GameScores` table's streams, but not to the table itself.

IAM policy to allow an AWS Lambda function to access DynamoDB stream records

If you want certain actions to be performed based on events in a DynamoDB stream, you can write an AWS Lambda function that is triggered by these events. A Lambda function such as this needs permissions to read data from a DynamoDB stream. For more information about using Lambda with DynamoDB Streams, see DynamoDB Streams and AWS Lambda triggers.

To grant permissions to Lambda, use the permissions policy that is associated with the Lambda function's IAM role (also known as an execution role). Specify this policy when you create the Lambda function.

For example, you can associate the following permissions policy with an execution role to grant Lambda permissions to perform the DynamoDB Streams actions listed.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "APIAccessForDynamoDBStreams",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator",
                "dynamodb:DescribeStream",
                "dynamodb:ListStreams"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/stream/*"
        }
    ]
```

```
}
```

For more information, see AWS Lambda permissions in the *AWS Lambda Developer Guide*.

IAM policy for read and write access to a DynamoDB Accelerator (DAX) cluster

The following policy allows read, write, update, and delete access to a DynamoDB Accelerator (DAX) cluster, but not to the associated DynamoDB table. To use this policy, substitute the AWS Region name, your account ID, and the name of your DAX cluster.

> **Note**
>
> This policy gives access to DAX cluster, but not to the associated DynamoDB table. Make sure that your DAX cluster has the correct policy to perform these same operations on the DynamoDB table on your behalf.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AmazonDynamoDBDAXDataOperations",
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:PutItem",
                "dax:ConditionCheckItem",
                "dax:BatchGetItem",
                "dax:BatchWriteItem",
                "dax:DeleteItem",
                "dax:Query",
                "dax:UpdateItem",
                "dax:Scan"
            ],
            "Resource": "arn:aws:dax:eu-west-1:123456789012:cache/MyDAXCluster"
        }
    ]
}
```

To expand this policy to cover DAX access for all AWS Regions for an account, use a wildcard character (*) for the Region name.

```
"Resource": "arn:aws:dax:*:123456789012:cache/MyDAXCluster"
```

IAM policy to grant access to search a vector index

The following policy grants permissions to perform `SearchVectors` operations on a specific vector index. The resource ARN for a vector index uses the same format as other DynamoDB indexes.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dynamodb:SearchVectors",
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Products/index/
ProductEmbeddingIndex"
        }
    ]
}
```

To grant `SearchVectors` access to all indexes on a table, use a wildcard character (*) for the index name.

```
"Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Products/index/*"
```

No additional permissions required

No additional IAM permissions are required to create or delete vector indexes. The existing `dynamodb:CreateTable` and `dynamodb:UpdateTable` permissions are sufficient.

FGAC condition keys not supported for SearchVectors

Fine-grained access control (FGAC) condition keys are not supported for the `SearchVectors` API. You cannot use `dynamodb:LeadingKeys`, `dynamodb:Attributes`, or `dynamodb:Select` condition keys to restrict `SearchVectors` access.

Troubleshooting Amazon DynamoDB identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with DynamoDB and IAM.

Topics

- I am not authorized to perform an action in DynamoDB
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my DynamoDB resources

I am not authorized to perform an action in DynamoDB

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a fictional *`my-example-widget`* resource but does not have the fictional `aws:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 aws:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *`my-example-widget`* resource using the `aws:`*`GetWidget`* action.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to DynamoDB.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in DynamoDB. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my DynamoDB resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether DynamoDB supports these features, see How Amazon DynamoDB works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

IAM policy to prevent the purchase of DynamoDB reserved capacity

With Amazon DynamoDB reserved capacity, you pay a one-time, upfront fee and commit to paying for a minimum usage level at significant savings over a period of time. You can use the AWS Management Console to view and purchase reserved capacity. However, you might not want all of the users in your organization to be able to purchase reserved capacity. For more information about reserved capacity, see Amazon DynamoDB pricing.

DynamoDB provides the following API operations for controlling access to reserved capacity management:

- dynamodb:DescribeReservedCapacity – Returns the reserved capacity purchases that are currently in effect.
- dynamodb:DescribeReservedCapacityOfferings – Returns details about the reserved capacity plans that are currently offered by AWS.
- dynamodb:PurchaseReservedCapacityOfferings – Performs an actual purchase of reserved capacity.

The AWS Management Console uses these API actions to display reserved capacity information and make purchases. You cannot call these operations from an application program because they can be accessed only from the console. However, you can allow or deny access to these operations in an IAM permissions policy.

The following policy allows users to view reserved capacity purchases and offerings by using the AWS Management Console — but new purchases are denied.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowReservedCapacityDescriptions",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeReservedCapacity",
                "dynamodb:DescribeReservedCapacityOfferings"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
        },
        {
            "Sid": "DenyReservedCapacityPurchases",
            "Effect": "Deny",
            "Action": "dynamodb:PurchaseReservedCapacityOfferings",
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
        }
    ]
}
```

Note that this policy uses the wildcard character (*) to allow describe permissions for all, and to deny the purchase of DynamoDB reserved capacity for all.

Using IAM policy conditions for fine-grained access control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect.

Overview

In DynamoDB, you have the option to specify conditions when granting permissions using an IAM policy (see Identity and Access Management for Amazon DynamoDB). For example, you can:

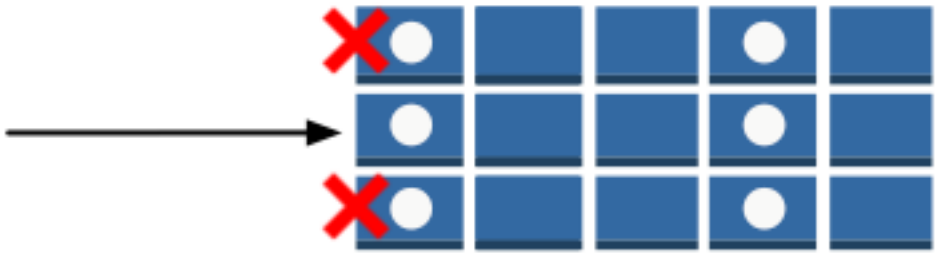
- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

In DynamoDB, you can specify conditions in an IAM policy using condition keys, as illustrated in the use case in the following section.

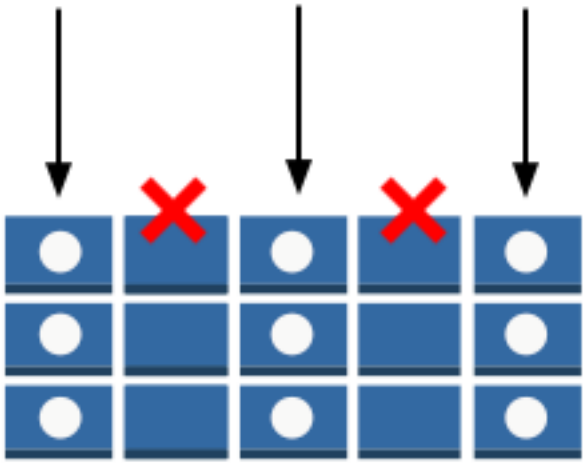
Permissions use case

In addition to controlling access to DynamoDB API actions, you can also control access to individual data items and attributes. For example, you can do the following:

- Grant permissions on a table, but restrict access to specific items in that table based on certain primary key values. An example might be a social networking app for games, where all users' saved game data is stored in a single table, but no users can access data items that they do not own, as shown in the following illustration:



- Hide information so that only a subset of attributes is visible to the user. An example might be an app that displays flight data for nearby airports, based on the user's location. Airline names, arrival and departure times, and flight numbers are all displayed. However, attributes such as pilot names or the number of passengers are hidden, as shown in the following illustration:



To implement this kind of fine-grained access control, you write an IAM permissions policy that specifies conditions for accessing security credentials and the associated permissions. You then apply the policy to users, groups, or roles that you create using the IAM console. Your IAM policy can restrict access to individual items in a table, access to the attributes in those items, or both at the same time.

You can optionally use web identity federation to control access by users who are authenticated by Login with Amazon, Facebook, or Google. For more information, see Using web identity federation.

You use the IAM `Condition` element to implement a fine-grained access control policy. By adding a `Condition` element to a permissions policy, you can allow or deny access to items and attributes in DynamoDB tables and indexes, based upon your particular business requirements.

The video below explains fine-grained access control in DynamoDB using IAM policy conditions.

Understanding Fine-Grained Access Control in DynamoDB

Fine-grained access control in DynamoDB allows you to create precise permissions boundaries at multiple levels:

1. **Item-level access control:** Restrict users to only access items that contain specific key values, typically matching their identity or permission scope.
2. **Attribute-level access control:** Limit which attributes (columns) users can view or modify, enabling you to protect sensitive information while allowing access to non-sensitive data within the same items.
3. **Operation-specific controls:** Apply different permission rules based on the type of operation being performed.

These controls are implemented through IAM policies using DynamoDB-specific condition keys.

Specifying conditions: Using condition keys

AWS provides a set of predefined condition keys (AWS-wide condition keys) for all AWS services that support IAM for access control. For example, you can use the `aws:SourceIp` condition key to check the requester's IP address before allowing an action to be performed. For more information and a list of the AWS-wide keys, see Available Keys for Conditions in the IAM User Guide.

The following are the DynamoDB service-specific condition keys that apply to DynamoDB.

`dynamodb:LeadingKeys`

Represents the first key attribute of a table—in other words, the partition key. The key name `LeadingKeys` is plural, even if the key is used with single-item actions. In addition, you must use the `ForAllValues` modifier when using `LeadingKeys` in a condition.

`dynamodb:Select`

Represents the `Select` parameter of a request. `Select` can be any of the following values:

- `ALL_ATTRIBUTES`

- `ALL_PROJECTED_ATTRIBUTES`
- `SPECIFIC_ATTRIBUTES`
- `COUNT`

> **Note**
>
> While often associated with Query and Scan operations, this condition key applies to all DynamoDB operations that return item attributes and is essential for controlling attribute access across all API actions. Using StringEqualsIfExists or similar constraints on this condition key will apply constraints on operations where this condition key applies, while ignoring it on operations where it does not apply.

`dynamodb:Attributes`

Represents a list of the *top-level* attributes accessed by a request. A top-level attribute is accessed by a request if it, or any nested attribute that it contains, is specified in the request parameters. For example, a `GetItem` request that specifies a `ProjectionExpression` of `"Name, Address.City"`, the `dynamodb:Attributes` list would include "Name" and "Address". If the `Attributes` parameter is enumerated in a fine grained access control policy then consider also restricting `ReturnValues` and `Select` parameters to ensure restricted access to specified attributes across multiple API actions like `GetItem`, `Query`, and `Scan`.

> **Note**
>
> This condition is evaluated only on the attributes specified in the request (such as in a ProjectionExpression), not on attributes in the response. If no ProjectionExpression is provided in the request, all attributes will be returned regardless of any attribute restrictions in the policy. See the section "Ensuring attribute-based restrictions are enforced" below for details on how to properly secure attribute access.

`dynamodb:ReturnValues`

Represents the `ReturnValues` parameter of a request. Depending on the API action, `ReturnValues` could be any of the following values:

- `ALL_OLD`

- UPDATED_OLD
- ALL_NEW
- UPDATED_NEW
- NONE

dynamodb:ReturnConsumedCapacity

Represents the ReturnConsumedCapacity parameter of a request. ReturnConsumedCapacity can be one of the following values:

- TOTAL
- NONE

dynamodb:FirstPartitionKeyValues

Represents the first key attribute of a table—in other words, the first partition key. The key name FirstPartitionKeyValues is plural, even if the key is used with single-item actions. In addition, you must use the ForAllValues modifier when using FirstPartitionKeyValues in a condition. FirstPartitionKeyValues and LeadingKeys can used exchangeable.

dynamodb:SecondPartitionKeyValues

Similar to dynamodb:FirstPartitionKeyValues. Represents resources' second partition key. The key name SecondPartitionKeyValues is plural, even if the key is used with single-item actions.

dynamodb:ThirdPartitionKeyValues

Similar to dynamodb:FirstPartitionKeyValues. Represents resources' third partition key. The key name ThirdPartitionKeyValues is plural, even if the key is used with single-item actions.

dynamodb:FourthPartitionKeyValues

Similar to dynamodb:FirstPartitionKeyValues. Represents resources' fourth partition key. The key name FourthPartitionKeyValues is plural, even if the key is used with single-item actions.

Ensuring attribute-based restrictions are enforced

When using attribute-based conditions to restrict access to specific attributes, it's important to understand how these conditions are evaluated:

- **Attribute conditions are evaluated only on attributes specified in the request**, not on attributes in the response.
- **For read operations without a ProjectionExpression** (GetItem, Query, Scan, etc.), all attributes will be returned regardless of attribute restrictions in your policy. To prevent this potential exposure of sensitive data, implement both attribute conditions (`dynamodb:Attributes`) and a condition requiring specific attributes must be requested (`dynamodb:Select`).
- **For write operations** (PutItem, UpdateItem, DeleteItem), the ReturnValues parameter can return complete items, potentially exposing restricted attributes even when the write operation itself complies with your policy. To prevent this exposure, implement both attribute conditions (`dynamodb:Attributes`) and restrictions on ReturnValues (`dynamodb:ReturnValues`) in your policy.

Limiting user access

Many IAM permissions policies allow users to access only those items in a table where the partition key value matches the user identifier. For example, the game app preceding limits access in this way so that users can only access game data that is associated with their user ID. The IAM substitution variables `${www.amazon.com:user_id}`, `${graph.facebook.com:id}`, and `${accounts.google.com:sub}` contain user identifiers for Login with Amazon, Facebook, and Google. To learn how an application logs in to one of these identity providers and obtains these identifiers, see Using web identity federation.

Important

Fine-grained access control isn't supported for restricting global tables replication. Applying policy conditions for fine-grained access control to DynamoDB service principals or service-linked roles used for global tables replication may interrupt replication within a global table.

Note

Each of the examples in the following section sets the `Effect` clause to `Allow` and specifies only the actions, resources, and parameters that are allowed. Access is permitted only to what is explicitly listed in the IAM policy.
In some cases, it is possible to rewrite these policies so that they are deny-based (that is, setting the `Effect` clause to `Deny` and inverting all of the logic in the policy). However,

we recommend that you avoid using deny-based policies with DynamoDB because they're difficult to write correctly, compared to allow-based policies. In addition, future changes to the DynamoDB API (or changes to existing API inputs) can render a deny-based policy ineffective.

Example policies: Using conditions for fine-grained access control

This section shows several policies for implementing fine-grained access control on DynamoDB tables and indexes.

Note

All examples use the us-west-2 Region and contain fictitious account IDs.

Example 1. Basic partition key-based access control with attribute restrictions

As an example, consider a mobile gaming app that lets players select from and play a variety of different games. The app uses a DynamoDB table named `GameScores` to keep track of high scores and other user data. Each item in the table is uniquely identified by a user ID and the name of the game that the user played. The `GameScores` table has a primary key consisting of a partition key (`UserId`) and sort key (`GameTitle`). Users only have access to game data associated with their user ID. A user who wants to play a game must belong to an IAM role named `GameRole`, which has a security policy attached to it.

To manage user permissions in this app, you could write a permissions policy such as the following:

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAccessToOnlyItemsMatchingUserID",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
```

```
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:BatchWriteItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ],
               "dynamodb:Attributes":[
                  "UserId",
                  "GameTitle",
                  "Wins",
                  "Losses",
                  "TopScore",
                  "TopScoreDateTime"
               ]
            },
            "StringEqualsIfExists":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES",
               "dynamodb:ReturnValues":[
                  "NONE",
                  "UPDATED_OLD",
                  "UPDATED_NEW"
               ]
            }
         }
      }
   ]
}
```

In addition to granting permissions for specific DynamoDB actions (`Action` element) on the `GameScores` table (`Resource` element), the `Condition` element uses the following condition keys specific to DynamoDB that limit the permissions as follows:

- `dynamodb:LeadingKeys` – This condition key allows users to access only the items where the partition key value matches their user ID. This ID, `${www.amazon.com:user_id}`, is a

substitution variable. For more information about substitution variables, see Using web identity federation.

- dynamodb:Attributes – This condition key limits access to the specified attributes so that only the actions listed in the permissions policy can return values for these attributes. In addition, the StringEqualsIfExists clause ensures that the app must always provide a list of specific attributes to act upon and that the app can't request all attributes.
- dynamodb:ReturnValues – This condition key restricts the ReturnValues parameter to NONE, UPDATED_OLD, or UPDATED_NEW. Write actions such as UpdateItem perform an implicit read to check whether an item exists before replacing it, and can return attribute values from before or after the update. Excluding ALL_OLD and ALL_NEW prevents the app from reading attributes that are not in the dynamodb:Attributes list.

When an IAM policy is evaluated, the result is always either true (access is allowed) or false (access is denied). If any part of the Condition element is false, the entire policy evaluates to false and access is denied.

> **Important**
>
> If you use dynamodb:Attributes, you must specify the names of all of the primary key and index key attributes for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can't use these key attributes to perform the requested action.

IAM policy documents can contain only the following Unicode characters: horizontal tab (U+0009), linefeed (U+000A), carriage return (U+000D), and characters in the range U+0020 to U+00FF.

Example 2: Grant permissions that limit access to items with a specific partition key value

The following permissions policy grants permissions that allow a set of DynamoDB actions on the GamesScore table. It uses the dynamodb:LeadingKeys condition key to limit user actions only on the items whose UserID partition key value matches the Login with Amazon unique user ID for this app.

> **Important**
>
> The list of actions does not include permissions for `Scan` because `Scan` returns all items regardless of the leading keys.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"FullAccessToUserItems",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:BatchWriteItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ]
            }
         }
      }
   ]
}
```

> **Note**
>
> When using policy variables, you must explicitly specify version 2012-10-17 in the policy. The default version of the access policy language, 2008-10-17, does not support policy variables.

To implement read-only access, you can remove any actions that can modify the data. In the following policy, only those actions that provide read-only access are included in the condition.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"ReadOnlyAccessToUserItems",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ]
            }
         }
      }
   ]
}
```

> **Important**
>
> If you use `dynamodb:Attributes`, you must specify the names of all of the primary key and index key attributes, for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can't use these key attributes to perform the requested action.

Example 3: Grant permissions that limit access to specific attributes in a table

The following permissions policy allows access to only two specific attributes in a table by adding the `dynamodb:Attributes` condition key. These attributes can be read, written, or evaluated in a conditional write or scan filter.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"LimitAccessToSpecificAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:UpdateItem",
            "dynamodb:GetItem",
            "dynamodb:Query",
            "dynamodb:BatchGetItem",
            "dynamodb:Scan"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:Attributes":[
                  "UserId",
                  "TopScore"
               ]
            },
            "StringEqualsIfExists":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES",
```

```
                "dynamodb:ReturnValues":[
                   "NONE",
                   "UPDATED_OLD",
                   "UPDATED_NEW"
                ]
             }
          }
       }
    ]
}
```

Note

The policy takes an allow list approach, which allows access to a named set of attributes. You can write an equivalent policy that denies access to other attributes instead. We don't recommend this deny list approach. Users can determine the names of these denied attributes by follow the principle of least privilege, as explained in Wikipedia at http://en.wikipedia.org/wiki/Principle_of_least_privilege, and use an allow list approach to enumerate all of the allowed values, rather than specifying the denied attributes.

This policy doesn't permit `PutItem`, `DeleteItem`, or `BatchWriteItem`. These actions always replace the entire previous item, which would allow users to delete the previous values for attributes that they are not allowed to access.

The `StringEqualsIfExists` clause in the permissions policy ensures the following:

- If the user specifies the `Select` parameter, then its value must be `SPECIFIC_ATTRIBUTES`. This requirement prevents the API action from returning any attributes that aren't allowed, such as from an index projection.
- If the user specifies the `ReturnValues` parameter, then its value must be `NONE`, `UPDATED_OLD`, or `UPDATED_NEW`. This is required because the `UpdateItem` action also performs implicit read operations to check whether an item exists before replacing it, and so that previous attribute values can be returned if requested. Restricting `ReturnValues` in this way ensures that users can only read or write the allowed attributes.
- The `StringEqualsIfExists` clause assures that only one of these parameters — `Select` or `ReturnValues` — can be used per request, in the context of the allowed actions.

The following are some variations on this policy:

- To allow only read actions, you can remove `UpdateItem` from the list of allowed actions. Because none of the remaining actions accept `ReturnValues`, you can remove `ReturnValues` from the condition. You can also change `StringEqualsIfExists` to `StringEquals` because the `Select` parameter always has a value (`ALL_ATTRIBUTES`, unless otherwise specified).
- To allow only write actions, you can remove everything except `UpdateItem` from the list of allowed actions. Because `UpdateItem` does not use the `Select` parameter, you can remove `Select` from the condition. You must also change `StringEqualsIfExists` to `StringEquals` because the `ReturnValues` parameter always has a value (`NONE` unless otherwise specified).
- To allow all attributes whose name matches a pattern, use `StringLike` instead of `StringEquals`, and use a multi-character pattern match wildcard character (*).

Example 4: Grant permissions to prevent updates on certain attributes

The following permissions policy limits user access to updating only the specific attributes identified by the `dynamodb:Attributes` condition key. The `StringNotLike` condition prevents an application from updating the attributes specified using the `dynamodb:Attributes` condition key.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"PreventUpdatesOnCertainAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:UpdateItem"
         ],
         "Resource":"arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
         "Condition":{
            "ForAllValues:StringNotLike":{
               "dynamodb:Attributes":[
                  "FreeGamesAvailable",
                  "BossLevelUnlocked"
               ]
            },
```

```
            "StringEqualsIfExists":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES",
               "dynamodb:ReturnValues":[
                  "NONE",
                  "UPDATED_OLD",
                  "UPDATED_NEW"
               ]
            }
         }
      }
   ]
}
```

Note the following:

- The `UpdateItem` action, like other write actions, requires read access to the items so that it can return values before and after the update. In the policy, you limit the action to accessing only the attributes that are allowed to be updated by specifying the `dynamodb:ReturnValues` condition key. The condition key restricts `ReturnValues` in the request to specify only `NONE`, `UPDATED_OLD`, or `UPDATED_NEW` and doesn't include `ALL_OLD` or `ALL_NEW`.
- The `StringEqualsIfExists` operator ensures that if `dynamodb:Select` or `dynamodb:ReturnValues` is present in the request, it must match the specified values. This prevents operations from returning complete items.
- When restricting attribute updates, you should also control what data can be returned to prevent information disclosure of protected attributes.
- The `PutItem` and `DeleteItem` actions replace an entire item, and thus allows applications to modify any attributes. So when limiting an application to updating only specific attributes, you should not grant permission for these APIs.

Example 5: Grant permissions to query only projected attributes in an index

The following permissions policy allows queries on a secondary index (`TopScoreDateTimeIndex`) by using the `dynamodb:Attributes` condition key. The policy also limits queries to requesting only specific attributes that have been projected into the index.

To require the application to specify a list of attributes in the query, the policy also specifies the `dynamodb:Select` condition key to require that the `Select` parameter of the DynamoDB `Query`

action is SPECIFIC_ATTRIBUTES. The list of attributes is limited to a specific list that is provided using the dynamodb:Attributes condition key.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"QueryOnlyProjectedIndexAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:Query"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/
TopScoreDateTimeIndex"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:Attributes":[
                  "TopScoreDateTime",
                  "GameTitle",
                  "Wins",
                  "Losses",
                  "Attempts"
               ]
            },
            "StringEquals":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES"
            }
         }
      }
   ]
}
```

The following permissions policy is similar, but the query must request all of the attributes that have been projected into the index.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"QueryAllIndexAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:Query"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/
TopScoreDateTimeIndex"
         ],
         "Condition":{
            "StringEquals":{
               "dynamodb:Select":"ALL_PROJECTED_ATTRIBUTES"
            }
         }
      }
   ]
}
```

Example 6: Grant permissions to limit access to certain attributes and partition key values

The following permissions policy allows specific DynamoDB actions (specified in the `Action` element) on a table and a table index (specified in the `Resource` element). The policy uses the `dynamodb:LeadingKeys` condition key to restrict permissions to only the items whose partition key value matches the user's Facebook ID.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"LimitAccessToCertainAttributesAndKeyValues",
         "Effect":"Allow",
         "Action":[
```

```
            "dynamodb:UpdateItem",
            "dynamodb:GetItem",
            "dynamodb:Query",
            "dynamodb:BatchGetItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/
TopScoreDateTimeIndex"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${graph.facebook.com:id}"
               ],
               "dynamodb:Attributes":[
                  "attribute-A",
                  "attribute-B"
               ]
            },
            "StringEqualsIfExists":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES",
               "dynamodb:ReturnValues":[
                  "NONE",
                  "UPDATED_OLD",
                  "UPDATED_NEW"
               ]
            }
         }
      }
   ]
}
```

Note the following:

- Write actions allowed by the policy (`UpdateItem`) can only modify attribute-A or attribute-B.
- Because the policy allows `UpdateItem`, an application can insert new items, and the hidden attributes will be null in the new items. If these attributes are projected into `TopScoreDateTimeIndex`, the policy has the added benefit of preventing queries that cause fetches from the table.

- Applications cannot read any attributes other than those listed in dynamodb:Attributes. With this policy in place, an application must set the Select parameter to SPECIFIC_ATTRIBUTES in read requests, and only attributes in the allow list can be requested. For write requests, the application cannot set ReturnValues to ALL_OLD or ALL_NEW and it cannot perform conditional write operations based on any other attributes.

Example 7: Deny permissions to limit access to specific attributes in a table

The following policy denies access to sensitive attributes and ensures this restriction cannot be bypassed by omitting a projection expression. It allows general access to the CustomerData table while explicitly denying access to SSN and CreditCardNumber attributes.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:Query",
            "dynamodb:Scan"
         ],
         "Resource":"arn:aws:dynamodb:us-west-2:123456789012:table/CustomerData"
      },
      {
         "Effect":"Deny",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:Query",
            "dynamodb:Scan"
         ],
         "Resource":"arn:aws:dynamodb:us-west-2:123456789012:table/CustomerData",
         "Condition":{
            "ForAnyValue:StringEquals":{
               "dynamodb:Attributes":[
                  "SSN",
                  "CreditCardNumber"
               ]
            }
```

```
            }
         },
         {
            "Effect":"Deny",
            "Action":[
               "dynamodb:GetItem",
               "dynamodb:Query",
               "dynamodb:Scan"
            ],
            "Resource":"arn:aws:dynamodb:us-west-2:123456789012:table/CustomerData",
            "Condition":{
               "StringNotEqualsIfExists":{
                  "dynamodb:Select":"SPECIFIC_ATTRIBUTES"
               }
            }
         }
      ]
}
```

Using web identity federation

If you are writing an application targeted at large numbers of users, you can optionally use *web identity federation* for authentication and authorization. Web identity federation removes the need for creating individual users. Instead, users can sign in to an identity provider and then obtain temporary security credentials from AWS Security Token Service (AWS STS). The app can then use these credentials to access AWS services.

Web identity federation supports the following identity providers:

- Login with Amazon
- Facebook
- Google

Additional resources for web identity federation

The following resources can help you learn more about web identity federation:

- The post Web Identity Federation using the AWS SDK for .NET on the AWS Developer blog walks through how to use web identity federation with Facebook. It includes code snippets in C# that show how to assume an IAM role with web identity and how to use temporary security credentials to access an AWS resource.
- The AWS Mobile SDK for iOS and the AWS Mobile SDK for Android contain sample apps. They include code that shows how to invoke the identity providers, and then how to use the information from these providers to get and use temporary security credentials.
- The article Web Identity Federation with Mobile Applications discusses web identity federation and shows an example of how to use web identity federation to access an AWS resource.

Example policy for web identity federation

To show how you can use web identity federation with DynamoDB, revisit the *GameScores* table that was introduced in Using IAM policy conditions for fine-grained access control. Here is the primary key for *GameScores*.

Table Name	Primary Key Type	Partition Key Name and Type	Sort Key Name and Type
GameScores (UserId, GameTitle, ...)	Composite	Attribute Name: UserId Type: String	Attribute Name: GameTitle Type: String

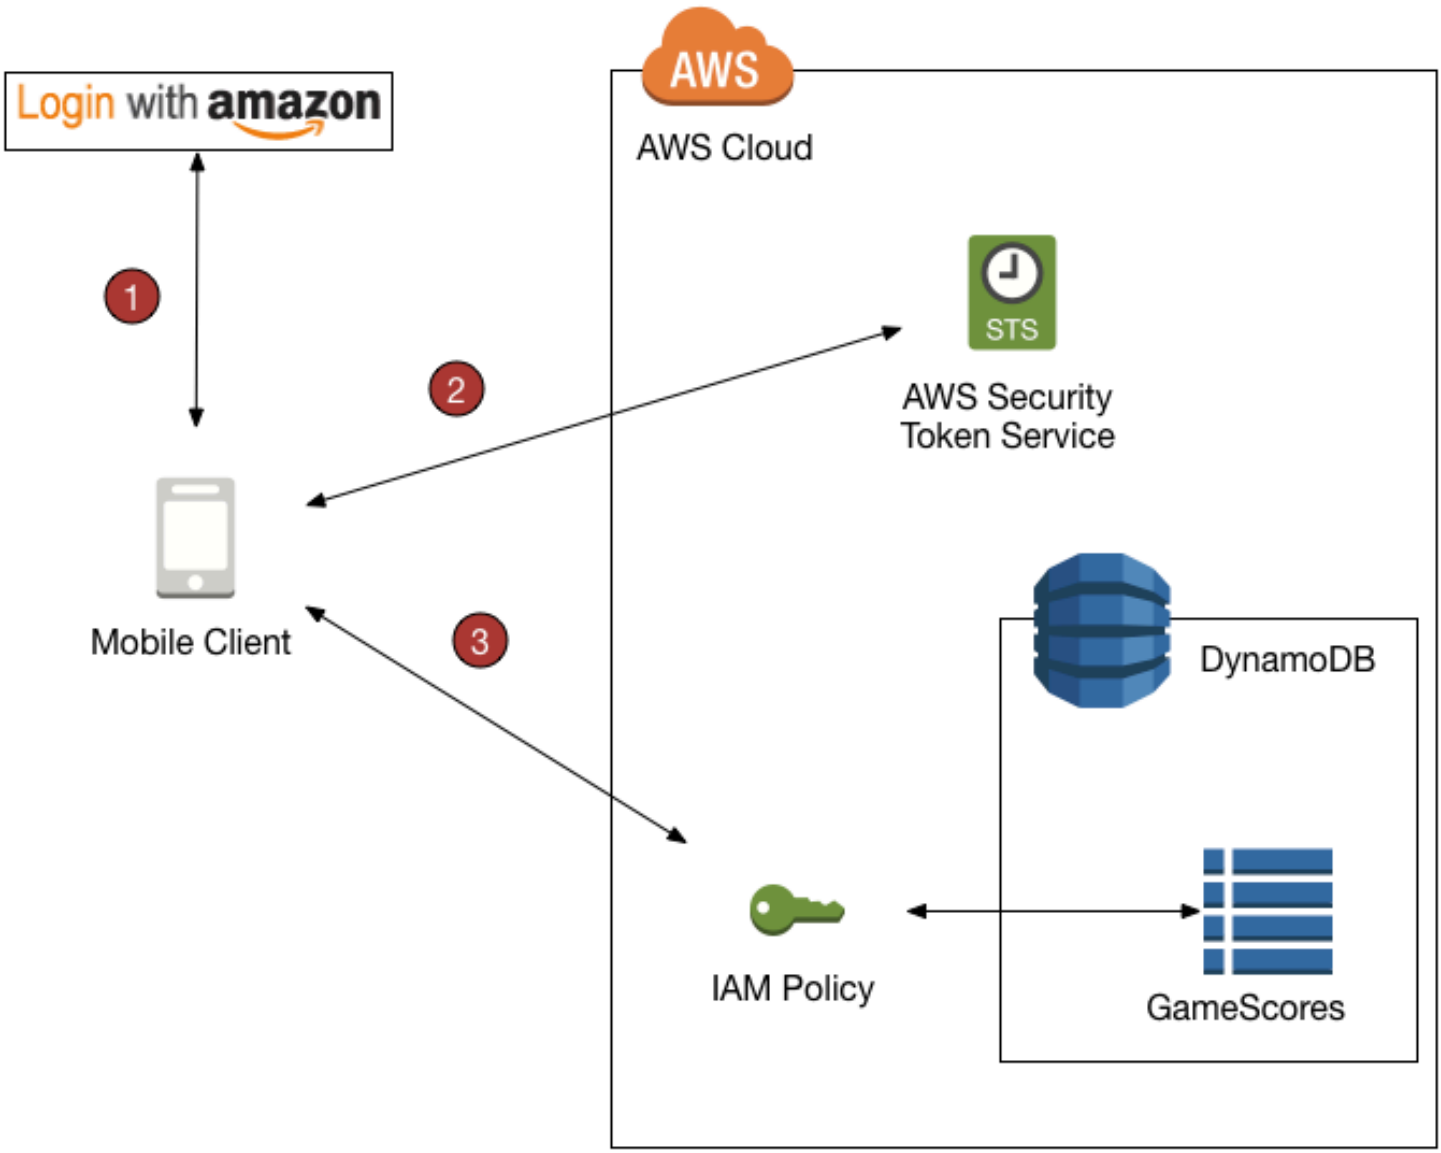
Now suppose that a mobile gaming app uses this table, and that app needs to support thousands, or even millions, of users. At this scale, it becomes very difficult to manage individual app users, and to guarantee that each user can only access their own data in the *GameScores* table. Fortunately, many users already have accounts with a third-party identity provider, such as Facebook, Google, or Login with Amazon. So it makes sense to use one of these providers for authentication tasks.

To do this using web identity federation, the app developer must register the app with an identity provider (such as Login with Amazon) and obtain a unique app ID. Next, the developer needs

to create an IAM role. (For this example, this role is named *GameRole*.) The role must have an IAM policy document attached to it, specifying the conditions under which the app can access *GameScores* table.

When a user wants to play a game, they sign in to their Login with Amazon account from within the gaming app. The app then calls AWS Security Token Service (AWS STS), providing the Login with Amazon app ID and requesting membership in *GameRole*. AWS STS returns temporary AWS credentials to the app and allows it to access the *GameScores* table, subject to the *GameRole* policy document.

The following diagram shows how these pieces fit together.



Web identity federation overview

1. The app calls a third-party identity provider to authenticate the user and the app. The identity provider returns a web identity token to the app.
2. The app calls AWS STS and passes the web identity token as input. AWS STS authorizes the app and gives it temporary AWS access credentials. The app is allowed to assume an IAM role (*GameRole*) and access AWS resources in accordance with the role's security policy.
3. The app calls DynamoDB to access the *GameScores* table. Because it has assumed the *GameRole*, the app is subject to the security policy associated with that role. The policy document prevents the app from accessing data that does not belong to the user.

Once again, here is the security policy for *GameRole* that was shown in Using IAM policy conditions for fine-grained access control:

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAccessToOnlyItemsMatchingUserID",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:BatchWriteItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ],
               "dynamodb:Attributes":[
```

```
                "UserId",
                "GameTitle",
                "Wins",
                "Losses",
                "TopScore",
                "TopScoreDateTime"
            ]
         },
         "StringEqualsIfExists":{
            "dynamodb:Select":"SPECIFIC_ATTRIBUTES",
            "dynamodb:ReturnValues":[
                "NONE",
                "UPDATED_OLD",
                "UPDATED_NEW"
            ]
         }
      }
   ]
}
```

The `Condition` clause determines which items in *GameScores* are visible to the app. It does this by comparing the Login with Amazon ID to the `UserId` partition key values in `GameScores`. Only the items belonging to the current user can be processed using one of DynamoDB actions that are listed in this policy. Other items in the table cannot be accessed. Furthermore, only the specific attributes listed in the policy can be accessed.

Preparing to use web identity federation

If you are an application developer and want to use web identity federation for your app, follow these steps:

1. **Sign up as a developer with a third-party identity provider.** The following external links provide information about signing up with supported identity providers:
   - Login with Amazon Developer Center
   - Registration on the Facebook site
   - Using OAuth 2.0 to Access Google APIs on the Google site

2. **Register your app with the identity provider.** When you do this, the provider gives you an ID that's unique to your app. If you want your app to work with multiple identity providers, you need to obtain an app ID from each provider.
3. **Create one or more IAM roles.** You need one role for each identity provider for each app. For example, you might create a role that can be assumed by an app where the user signed in using Login with Amazon, a second role for the same app where the user has signed in using Facebook, and a third role for the app where users sign in using Google.

   As part of the role creation process, you need to attach an IAM policy to the role. Your policy document should define the DynamoDB resources required by your app, and the permissions for accessing those resources.

For more information, see About Web Identity Federation in *IAM User Guide*.

> **Note**
>
> As an alternative to AWS Security Token Service, you can use Amazon Cognito. Amazon Cognito is the preferred service for managing temporary credentials for mobile apps. For more information, see Getting credentials in the *Amazon Cognito Developer Guide.*

Generating an IAM policy using the DynamoDB console

The DynamoDB console can help you create an IAM policy for use with web identity federation. To do this, you choose a DynamoDB table and specify the identity provider, actions, and attributes to be included in the policy. The DynamoDB console then generates a policy that you can attach to an IAM role.

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane, choose **Tables**.
3. In the list of tables, choose the table for which you want to create the IAM policy.
4. Select the **Actions** button, and choose **Create Access Control Policy**.
5. Choose the identity provider, actions, and attributes for the policy.

   When the settings are as you want them, choose **Generate Policy**. The generated policy appears.

6. Choose **See Documentation**, and follow the steps required to attach the generated policy to an IAM role.

Writing your app to use web identity federation

To use web identity federation, your app must assume the IAM role that you created. From that point on, the app honors the access policy that you attached to the role.

At runtime, if your app uses web identity federation, it must follow these steps:

1. **Authenticate with a third-party identity provider.** Your app must call the identity provider using an interface that they provide. The exact way in which you authenticate the user depends on the provider and on what platform your app is running. Typically, if the user is not already signed in, the identity provider takes care of displaying a sign-in page for that provider.

   After the identity provider authenticates the user, the provider returns a web identity token to your app. The format of this token depends on the provider, but is typically a very long string of characters.
2. **Obtain temporary AWS security credentials.** To do this, your app sends a `AssumeRoleWithWebIdentity` request to AWS Security Token Service (AWS STS). This request contains the following:
   - The web identity token from the previous step
   - The app ID from the identity provider
   - The Amazon Resource Name (ARN) of the IAM role that you created for this identity provider for this app

   AWS STS returns a set of AWS security credentials that expire after a certain amount of time (3,600 seconds, by default).

   The following is a sample request and response from a `AssumeRoleWithWebIdentity` action in AWS STS. The web identity token was obtained from the Login with Amazon identity provider.

```
GET / HTTP/1.1
Host: sts.amazonaws.com
Content-Type: application/json; charset=utf-8
URL: https://sts.amazonaws.com/?ProviderId=www.amazon.com
&DurationSeconds=900&Action=AssumeRoleWithWebIdentity
&Version=2011-06-15&RoleSessionName=web-identity-federation
&RoleArn=arn:aws:iam::123456789012:role/GameRole
```

```
&WebIdentityToken=Atza|IQEBLjAsAhQluyKqyBiYZ8-kclvGTYM81e...(remaining characters
 omitted)
```

```
<AssumeRoleWithWebIdentityResponse
  xmlns="https://sts.amazonaws.com/doc/2011-06-15/">
  <AssumeRoleWithWebIdentityResult>
    <SubjectFromWebIdentityToken>amzn1.account.AGJZDKHJKAUUSW6C44CHPEXAMPLE</
SubjectFromWebIdentityToken>
    <Credentials>
      <SessionToken>AQoDYXdzEMf//////////wEa8AP6nNDwcSLnf+cHupC...(remaining
 characters omitted)</SessionToken>
      <SecretAccessKey>8Jhi60+EWUUbbUShTEsjTxqQtM8UKvsM6XAjdA==</SecretAccessKey>
      <Expiration>2013-10-01T22:14:35Z</Expiration>
      <AccessKeyId>06198791C436IEXAMPLE</AccessKeyId>
    </Credentials>
    <AssumedRoleUser>
      <Arn>arn:aws:sts::123456789012:assumed-role/GameRole/web-identity-federation</
Arn>
      <AssumedRoleId>AROAJU4SA2VW5SZRF2YMG:web-identity-federation</AssumedRoleId>
    </AssumedRoleUser>
  </AssumeRoleWithWebIdentityResult>
  <ResponseMetadata>
    <RequestId>c265ac8e-2ae4-11e3-8775-6969323a932d</RequestId>
  </ResponseMetadata>
</AssumeRoleWithWebIdentityResponse>
```

3. **Access AWS resources.** The response from AWS STS contains information that your app requires in order to access DynamoDB resources:

   - The `AccessKeyID`, `SecretAccessKey`, and `SessionToken` fields contain security credentials that are valid for this user and this app only.
   - The `Expiration` field signifies the time limit for these credentials, after which they are no longer valid.
   - The `AssumedRoleId` field contains the name of a session-specific IAM role that has been assumed by the app. The app honors the access controls in the IAM policy document for the duration of this session.
   - The `SubjectFromWebIdentityToken` field contains the unique ID that appears in an IAM policy variable for this particular identity provider. The following are the IAM policy variables for supported providers, and some example values for them:

Policy Variable	Example Value
`${www.amazon.com:user_id}`	`amzn1.account.AGJZDKHJKAUUSW6C44CHPEXAMPLE`
`${graph.facebook.com:id}`	`123456789`
`${accounts.google.com:sub}`	`12345678901234567890 1`

For example IAM policies where these policy variables are used, see Example policies: Using conditions for fine-grained access control.

For more information about how AWS STS generates temporary access credentials, see Requesting Temporary Security Credentials in *IAM User Guide*.

DynamoDB API permissions: Actions, resources, and conditions reference

When you are setting up Identity and Access Management for Amazon DynamoDB and writing a permissions policy that you can attach to an IAM identity (identity-based policies), you can use the list of Actions, resources, and condition keys for Amazon DynamoDB in the *IAM User Guide* as a reference. The page lists each DynamoDB API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's `Action` field, and you specify the resource value in the policy's `Resource` field.

You can use AWS-wide condition keys in your DynamoDB policies to express conditions. For a complete list of AWS-wide keys, see the IAM JSON policy elements reference in the *IAM User Guide*.

In addition to the AWS-wide condition keys, DynamoDB has its own specific keys that you can use in conditions. For more information, see Using IAM policy conditions for fine-grained access control.

Compliance validation by industry for DynamoDB

Our new AWS sign-up experience is not designed for regulated workloads. If you're using our new AWS sign-up experience, but you want to use AWS for regulated workloads, you can sign up for AWS (advanced) or activate advanced features for your AWS environment.

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. For more information about your compliance responsibility when using AWS services, see AWS Security Documentation.

Resilience and disaster recovery in Amazon DynamoDB

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

Amazon DynamoDB automatically replicates your data across three Availability Zones in a Region, providing built-in high durability and a 99.99% availability SLA. In addition, DynamoDB offers several features to help support your data resiliency and backup needs.

On-demand backup and restore

DynamoDB provides on-demand backup capability. It allows you to create full backups of your tables for long-term retention and archival. For more information, see On-Demand backup and restore for DynamoDB.

Point-in-time recovery

Point-in-time recovery helps protect your DynamoDB tables from accidental write or delete operations. With point in time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For more information, see Point-in-time recovery for DynamoDB.

Global tables that sync across AWS regions

DynamoDB automatically spreads the data and traffic for your tables over a sufficient number of servers to handle your throughput and storage requirements, while maintaining consistent and fast performance. All of your data is stored on solid-state disks (SSDs) and is automatically replicated across multiple Availability Zones in an AWS Region, providing built-in high availability and data durability. You can use global tables to keep DynamoDB tables in sync across AWS Regions.

Infrastructure security in Amazon DynamoDB

As a managed service, Amazon DynamoDB is protected by the AWS global network security procedures that are described in Infrastructure protection located in the AWS Well-Architected Framework.

You use AWS published API calls to access DynamoDB through the network. Clients can use TLS (Transport Layer Security) version 1.2 or 1.3. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, requests must be signed using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

You can also use a virtual private cloud (VPC) endpoint for DynamoDB to enable Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. For more information, see Using Amazon VPC endpoints to access DynamoDB.

Using Amazon VPC endpoints to access DynamoDB

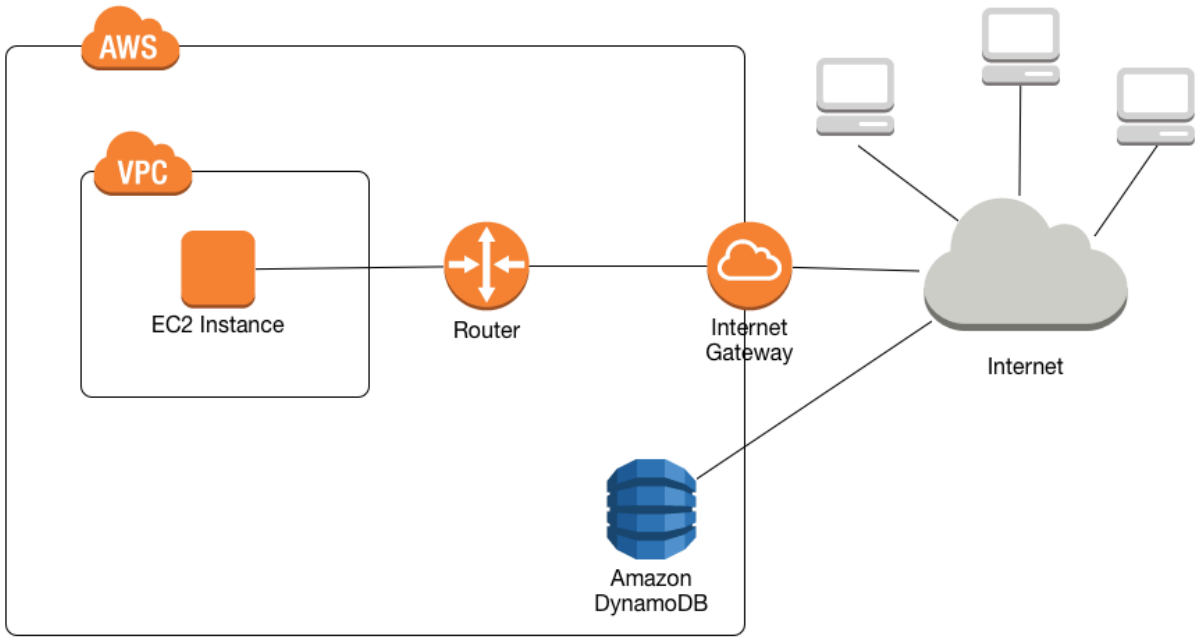
For security reasons, many AWS customers run their applications within an Amazon Virtual Private Cloud environment (Amazon VPC). With Amazon VPC, you can launch Amazon EC2 instances into a

virtual private cloud, which is logically isolated from other networks—including the public internet. With an Amazon VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings.

> **Note**
>
> If you created your AWS account after December 4, 2013, then you already have a default VPC in each AWS Region. A default VPC is ready for you to use—you can immediately start using it without having to perform any additional configuration steps.
> For more information, see Default VPC and Default Subnets in the *Amazon VPC User Guide*.

To access the public internet, your VPC must have an internet gateway—a virtual router that connects your VPC to the internet. This allows applications running on Amazon EC2 in your VPC to access internet resources, such as Amazon DynamoDB.

By default, communications to and from DynamoDB use the HTTPS protocol, which protects network traffic by using SSL/TLS encryption. The following diagram shows an Amazon EC2 instance in a VPC accessing DynamoDB, by having DynamoDB use an internet gateway rather than VPC endpoints.



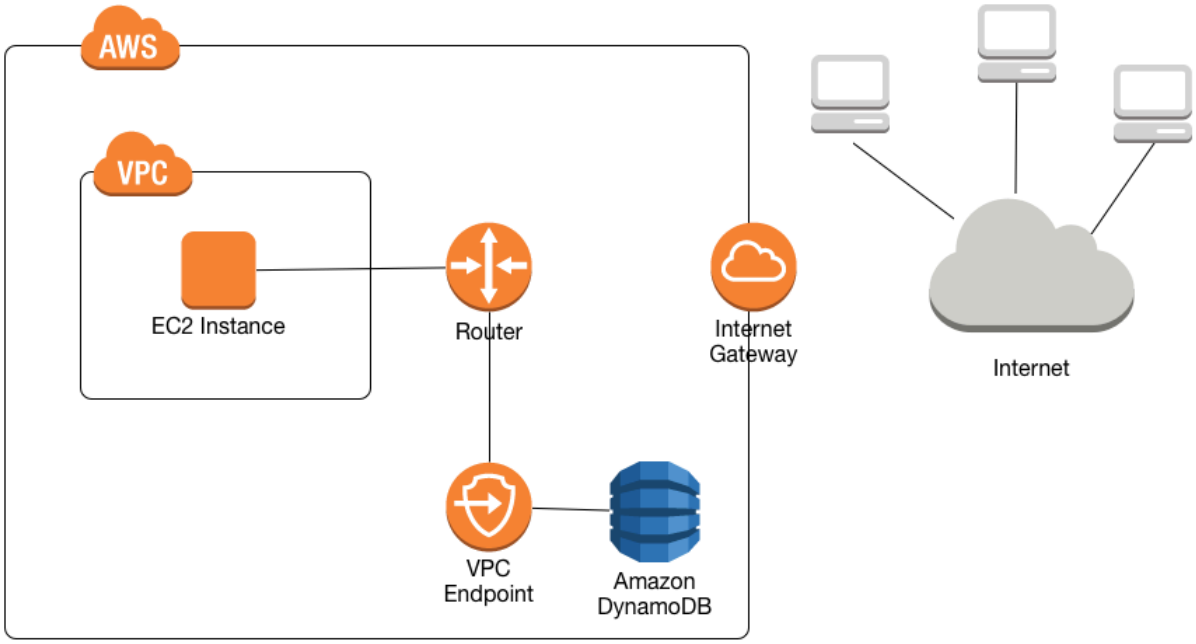
Many customers have legitimate privacy and security concerns about sending and receiving data across the public internet. You can address these concerns by using a virtual private network (VPN) to route all DynamoDB network traffic through your own corporate network infrastructure. However, this approach can introduce bandwidth and availability challenges.

VPC endpoints for DynamoDB can alleviate these challenges. A *VPC endpoint* for DynamoDB enables Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. Your EC2 instances do not require public IP addresses, and you don't need an internet gateway, a NAT device, or a virtual private gateway in your VPC. You use endpoint policies to control access to DynamoDB. Traffic between your VPC and the AWS service does not leave the Amazon network.

> **Note**
>
> Even when you use public IP addresses, all VPC communication between instances and services hosted in AWS is kept private within the AWS network. Packets that originate from the AWS network with a destination on the AWS network stay on the AWS global network, except traffic to or from AWS China Regions.

When you create a VPC endpoint for DynamoDB, any requests to a DynamoDB endpoint within the Region (for example, *dynamodb.us-west-2.amazonaws.com*) are routed to a private DynamoDB endpoint within the Amazon network. You don't need to modify your applications running on EC2 instances in your VPC. The endpoint name remains the same, but the route to DynamoDB stays entirely within the Amazon network, and does not access the public internet.

The following diagram shows how an EC2 instance in a VPC can use a VPC endpoint to access DynamoDB.



For more information, see the section called "Tutorial: Using a VPC endpoint for DynamoDB".

Sharing Amazon VPC endpoints and DynamoDB

In order to enable access to the DynamoDB service through a VPC subnet's gateway endpoint, you must have owner account permissions for that VPC subnet.

After the VPC subnet's gateway endpoint has been granted access to DynamoDB, any AWS account with access to that subnet can use DynamoDB. This means all account users within the VPC subnet can use any DynamoDB tables which they have access to. This includes DynamoDB tables associated with a different account than the VPC subnet. The VPC subnet owner can still restrict any particular user within the subnet from using the DynamoDB service through the gateway endpoint, at their discretion.

Tutorial: Using a VPC endpoint for DynamoDB

This section walks you through setting up and using a VPC endpoint for DynamoDB.

Topics

- Step 1: Launch an Amazon EC2 instance
- Step 2: Configure your Amazon EC2 instance

- Step 3: Create a VPC endpoint for DynamoDB
- Step 4: (Optional) Clean up

Step 1: Launch an Amazon EC2 instance

In this step, you launch an Amazon EC2 instance in your default Amazon VPC. You can then create and use a VPC endpoint for DynamoDB.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance** and do the following:

   Step 1: Choose an Amazon Machine Image (AMI)

   - At the top of the list of AMIs, go to **Amazon Linux AMI** and choose **Select**.

   Step 2: Choose an Instance Type

   - At the top of the list of instance types, choose **t2.micro**.
   - Choose **Next: Configure Instance Details**.

   Step 3: Configure Instance Details

   - Go to **Network** and choose your default VPC.

     Choose **Next: Add Storage**.

   Step 4: Add Storage

   - Skip this step by choosing **Next: Tag Instance**.

   Step 5: Tag Instance

   - Skip this step by choosing **Next: Configure Security Group**.

   Step 6: Configure Security Group

   - Choose **Select an existing security group**.

- In the list of security groups, choose **default**. This is the default security group for your VPC.
- Choose **Next: Review and Launch**.

Step 7: Review Instance Launch

- Choose **Launch**.

3. In the **Select an existing key pair or create a new key pair** window, do one of the following:
   - If you do not have an Amazon EC2 key pair, choose **Create a new key pair** and follow the instructions. You will be asked to download a private key file (*.pem* file); you will need this file later when you log in to your Amazon EC2 instance.
   - If you already have an existing Amazon EC2 key pair, go to **Select a key pair** and choose your key pair from the list. You must already have the private key file (*.pem* file) available in order to log in to your Amazon EC2 instance.
4. When you have configured your key pair, choose **Launch Instances**.
5. Return to the Amazon EC2 console home page and choose the instance that you launched. In the lower pane, on the **Description** tab, find the **Public DNS** for your instance. For example: `ec2-00-00-00-00.us-east-1.compute.amazonaws.com`.

   Make a note of this public DNS name, because you will need it in the next step in this tutorial (Step 2: Configure your Amazon EC2 instance).

> **Note**
>
> It will take a few minutes for your Amazon EC2 instance to become available. Before you go on to the next step, make sure that the **Instance State** is `running` and that all of its **Status Checks** have passed.

Step 2: Configure your Amazon EC2 instance

When your Amazon EC2 instance is available, you will be able to log into it and prepare it for first use.

> **Note**
>
> The following steps assume that you are connecting to your Amazon EC2 instance from a computer running Linux. For other ways to connect, see Connect to Your Linux Instance in the Amazon EC2 User Guide.

1. You will need to authorize inbound SSH traffic to your Amazon EC2 instance. To do this, you will create a new EC2 security group, and then assign the security group to your EC2 instance.

   a. In the navigation pane, choose **Security Groups**.

   b. Choose **Create Security Group**. In the **Create Security Group** window, do the following:

      - **Security group name**—type a name for your security group. For example: `my-ssh-access`
      - **Description**—type a short description for the security group.
      - **VPC**—choose your default VPC.
      - In the **Security group rules** section, choose **Add Rule** and do the following:
        - **Type**—choose SSH.
        - **Source**—choose My IP.

      When the settings are as you want them, choose **Create**.

   c. In the navigation pane, choose **Instances**.

   d. Choose the Amazon EC2 instance that you launched in Step 1: Launch an Amazon EC2 instance.

   e. Choose **Actions** --> **Networking** --> **Change Security Groups**.

   f. In the **Change Security Groups**, select the security group that you created earlier in this procedure (for example: `my-ssh-access`). The existing `default` security group should also be selected. When the settings are as you want them, choose **Assign Security Groups**.

2. Use the `ssh` command to log in to your Amazon EC2 instance, as in the following example.

   ```
   ssh -i my-keypair.pem ec2-user@public-dns-name
   ```

   You will need to specify your private key file (*.pem* file) and the public DNS name of your instance. (See Step 1: Launch an Amazon EC2 instance).

The login ID is `ec2-user`. No password is required.

3. Configure your AWS credentials as shown in the following example. Enter your AWS access key ID, secret key, and default Region name when prompted.

```
aws configure
```

```
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-east-1
Default output format [None]:
```

You are now ready to create a VPC endpoint for DynamoDB.

Step 3: Create a VPC endpoint for DynamoDB

In this step, you will create a VPC endpoint for DynamoDB and test it to make sure that it works.

1. Before you begin, verify that you can communicate with DynamoDB using its public endpoint.

```
aws dynamodb list-tables
```

The output will show a list of DynamoDB tables that you currently own. (If you don't have any tables, the list will be empty.).

2. Verify that DynamoDB is an available service for creating VPC endpoints in the current AWS Region. (The command is shown in bold text, followed by example output.)

```
aws ec2 describe-vpc-endpoint-services
```

```
{
    "ServiceNames": [
        "com.amazonaws.us-east-1.s3",
        "com.amazonaws.us-east-1.dynamodb"
    ]
}
```

In the example output, DynamoDB is one of the services available, so you can proceed with creating a VPC endpoint for it.

3. Determine your VPC identifier.

```
aws ec2 describe-vpcs
```

```
{
    "Vpcs": [
        {
            "VpcId": "vpc-0bbc736e",
            "InstanceTenancy": "default",
            "State": "available",
            "DhcpOptionsId": "dopt-8454b7e1",
            "CidrBlock": "172.31.0.0/16",
            "IsDefault": true
        }
    ]
}
```

In the example output, the VPC ID is `vpc-0bbc736e`.

4. Create the VPC endpoint. For the `--vpc-id` parameter, specify the VPC ID from the previous step. Use the `--route-table-ids` parameter to associate the endpoint with your route tables.

```
aws ec2 create-vpc-endpoint --vpc-id vpc-0bbc736e --service-name com.amazonaws.us-
east-1.dynamodb --route-table-ids rtb-11aa22bb
```

```
{
    "VpcEndpoint": {
        "PolicyDocument": "{\"Version\":\"2008-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":\"*\",\"Action\":\"*\",\"Resource\":\"*\"}]}",
        "VpcId": "vpc-0bbc736e",
        "State": "available",
        "ServiceName": "com.amazonaws.us-east-1.dynamodb",
        "RouteTableIds": [
            "rtb-11aa22bb"
        ],
        "VpcEndpointId": "vpce-9b15e2f2",
        "CreationTimestamp": "2017-07-26T22:00:14Z"
    }
}
```

5. Verify that you can access DynamoDB through the VPC endpoint.

```
aws dynamodb list-tables
```

If you want, you can try some other AWS CLI commands for DynamoDB. For more information, see the AWS CLI Command Reference.

Step 4: (Optional) Clean up

If you want to delete the resources you have created in this tutorial, follow these procedures:

To remove your VPC endpoint for DynamoDB

1. Log in to your Amazon EC2 instance.
2. Determine the VPC endpoint ID.

```
aws ec2 describe-vpc-endpoints
```

```
{
    "VpcEndpoint": {
        "PolicyDocument": "{\"Version\":\"2008-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":\"*\",\"Action\":\"*\",\"Resource\":\"*\"}]}",
        "VpcId": "vpc-0bbc736e",
        "State": "available",
        "ServiceName": "com.amazonaws.us-east-1.dynamodb",
        "RouteTableIds": [],
        "VpcEndpointId": "vpce-9b15e2f2",
        "CreationTimestamp": "2017-07-26T22:00:14Z"
    }
}
```

In the example output, the VPC endpoint ID is `vpce-9b15e2f2`.

3. Delete the VPC endpoint.

```
aws ec2 delete-vpc-endpoints --vpc-endpoint-ids vpce-9b15e2f2
```

```
{
    "Unsuccessful": []
```

```
}
```

The empty array `[]` indicates success (there were no unsuccessful requests).

To terminate your Amazon EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Choose your Amazon EC2 instance.
4. Choose **Actions**, **Instance State**, **Terminate**.
5. In the confirmation window, choose **Yes, Terminate**.

AWS PrivateLink for DynamoDB

With AWS PrivateLink for DynamoDB, you can provision *interface Amazon VPC endpoints* (interface endpoints) in your virtual private cloud (Amazon VPC). These endpoints are directly accessible from applications that are on premises over VPN and Direct Connect, or in a different AWS Region over Amazon VPC peering. Using AWS PrivateLink and interface endpoints, you can simplify private network connectivity from your applications to DynamoDB.

Applications in your VPC do not need public IP addresses to communicate with DynamoDB using VPC interface endpoints for DynamoDB operations. Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your Amazon VPC. Requests to DynamoDB over interface endpoints stay on the Amazon network. You can also access interface endpoints in your Amazon VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (Site-to-Site VPN). For more information about how to connect your Amazon VPC with your on-premises network, see the Direct Connect User Guide and the AWS Site-to-Site VPN User Guide.

For general information about interface endpoints, see Interface Amazon VPC endpoints (AWS PrivateLink) in the *AWS PrivateLink Guide*. AWS PrivateLink is also supported for Amazon DynamoDB Streams endpoints. For more information, see the section called “AWS PrivateLink for DynamoDB Streams”.

Topics

- Types of Amazon VPC endpoints for Amazon DynamoDB

- Considerations when using AWS PrivateLink for Amazon DynamoDB
- Creating an Amazon VPC endpoint
- Accessing Amazon DynamoDB interface endpoints
- Accessing DynamoDB tables and control API operations from DynamoDB interface endpoints
- Updating an on-premises DNS configuration
- Creating an Amazon VPC endpoint policy for DynamoDB
- Using DynamoDB endpoints with AWS Management Console Private Access
- AWS PrivateLink for DynamoDB Streams
- Using AWS PrivateLink for DynamoDB Accelerator (DAX)

Types of Amazon VPC endpoints for Amazon DynamoDB

You can use two types of Amazon VPC endpoints to access Amazon DynamoDB: *gateway endpoints* and *interface endpoints* (by using AWS PrivateLink). A *gateway endpoint* is a gateway that you specify in your route table to access DynamoDB from your Amazon VPC over the AWS network. *Interface endpoints* extend the functionality of gateway endpoints by using private IP addresses to route requests to DynamoDB from within your Amazon VPC, on premises, or from an Amazon VPC in another AWS Region by using Amazon VPC peering or AWS Transit Gateway. For more information, see What is Amazon VPC peering? and Transit Gateway vs Amazon VPC peering.

Interface endpoints are compatible with gateway endpoints. If you have an existing gateway endpoint in the Amazon VPC, you can use both types of endpoints in the same Amazon VPC.

Gateway endpoints for DynamoDB	Interface endpoints for DynamoDB
In both cases, your network traffic remains on the AWS network.	
Use Amazon DynamoDB public IP addresses	Use private IP addresses from your Amazon VPC to access Amazon DynamoDB
Do not allow access from on premises	Allow access from on premises
Do not allow access from another AWS Region	Allow access from an Amazon VPC endpoint in another AWS Region by using Amazon VPC peering or AWS Transit Gateway

Gateway endpoints for DynamoDB	Interface endpoints for DynamoDB
Not billed	Billed

For more information about gateway endpoints, see Gateway Amazon VPC endpoints in the *AWS PrivateLink Guide*.

Considerations when using AWS PrivateLink for Amazon DynamoDB

Amazon VPC considerations apply to AWS PrivateLink for Amazon DynamoDB. For more information, see Interface endpoint considerations and AWS PrivateLink quotas in the *AWS PrivateLink Guide*. In addition, the following restrictions apply.

AWS PrivateLink for Amazon DynamoDB does not support the following:

- Transport Layer Security (TLS) 1.1
- Private and Hybrid Domain Name System (DNS) services

> **Important**
>
> Do not create private hosted zones to override DynamoDB endpoint DNS names (such as `dynamodb.region.amazonaws.com` or `*.region.amazonaws.com`) to route traffic to your interface endpoints. DynamoDB DNS configurations might change over time. Custom DNS overrides are not compatible with these changes and can cause requests to unexpectedly route over public IP addresses instead of your interface endpoints. To access DynamoDB through AWS PrivateLink, configure your clients to use the Amazon VPC endpoint URL directly (for example, `https://vpce-1a2b3c4d-5e6f.dynamodb.region.vpce.amazonaws.com`).

You can submit up to 50,000 requests per second for each AWS PrivateLink endpoint that you enable.

> **Note**
>
> Network connectivity timeouts to AWS PrivateLink endpoints are not within the scope of DynamoDB error responses and need to be appropriately handled by your applications connecting to the PrivateLink endpoints.

Creating an Amazon VPC endpoint

To create an Amazon VPC interface endpoint, see Create an Amazon VPC endpoint in the *AWS PrivateLink Guide*.

Accessing Amazon DynamoDB interface endpoints

When you create an interface endpoint, DynamoDB generates two types of endpoint-specific, DynamoDB DNS names: *Regional* and *Zonal*.

- A *Regional* DNS name includes a unique Amazon VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for Amazon VPC endpoint ID *`vpce-1a2b3c4d`*, the DNS name generated might be similar to *`vpce-1a2b3c4d-5e6f`*`.dynamodb.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, *`vpce-1a2b3c4d-5e6f`*`-us-east-1a.dynamodb.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

> **Note**
>
> To achieve optimal reliability, we recommend deploying your service across a minimum of three availability zones.

Accessing DynamoDB tables and control API operations from DynamoDB interface endpoints

You can use the AWS CLI or AWS SDKs to access DynamoDB tables and control API operations through DynamoDB interface endpoints.

AWS CLI examples

To access DynamoDB tables or DynamoDB control API operations through DynamoDB interface endpoints in AWS CLI commands, use the `--region` and `--endpoint-url` parameters.

Example: Create a VPC endpoint

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name com.amazonaws.us-east-1.dynamodb \
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface \
--security-group-ids client-sg-id
```

Example: Modify a VPC endpoint

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-endpoint-id \
--policy-document policy-document \ #example optional parameter
--add-security-group-ids security-group-ids \ #example optional parameter
# any additional parameters needed, see Privatelink documentation for more details
```

Example: List tables using an endpoint URL

In the following example, replace the Region `us-east-1` and the DNS name of the VPC endpoint ID `vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
aws dynamodb --region us-east-1 --endpoint https://vpce-1a2b3c4d-5e6f.dynamodb.us-
east-1.vpce.amazonaws.com list-tables
```

AWS SDK examples

To access DynamoDB tables or DynamoDB control API operations through DynamoDB interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then, configure your clients to use an endpoint URL for accessing a table or DynamoDB control API operation through DynamoDB interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access a DynamoDB table

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
ddb_client = session.client(
service_name='dynamodb',
region_name='us-east-1',
endpoint_url='https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com'
)
```

SDK for Java 1.x

Example: Use an endpoint URL to access a DynamoDB table

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
//client build with endpoint config
final AmazonDynamoDB dynamodb =
 AmazonDynamoDBClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
```

SDK for Java 2.x

Example: Use an endpoint URL to access DynamoDB table

In the following example, replace the Region us-east-1 and VPC endpoint ID https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com with your own information.

```
Region region = Region.US_EAST_1;
dynamoDbClient = DynamoDbClient.builder().region(region)
.endpointOverride(URI.create("https://vpce-1a2b3c4d-5e6f.dynamodb.us-
east-1.vpce.amazonaws.com"))
```

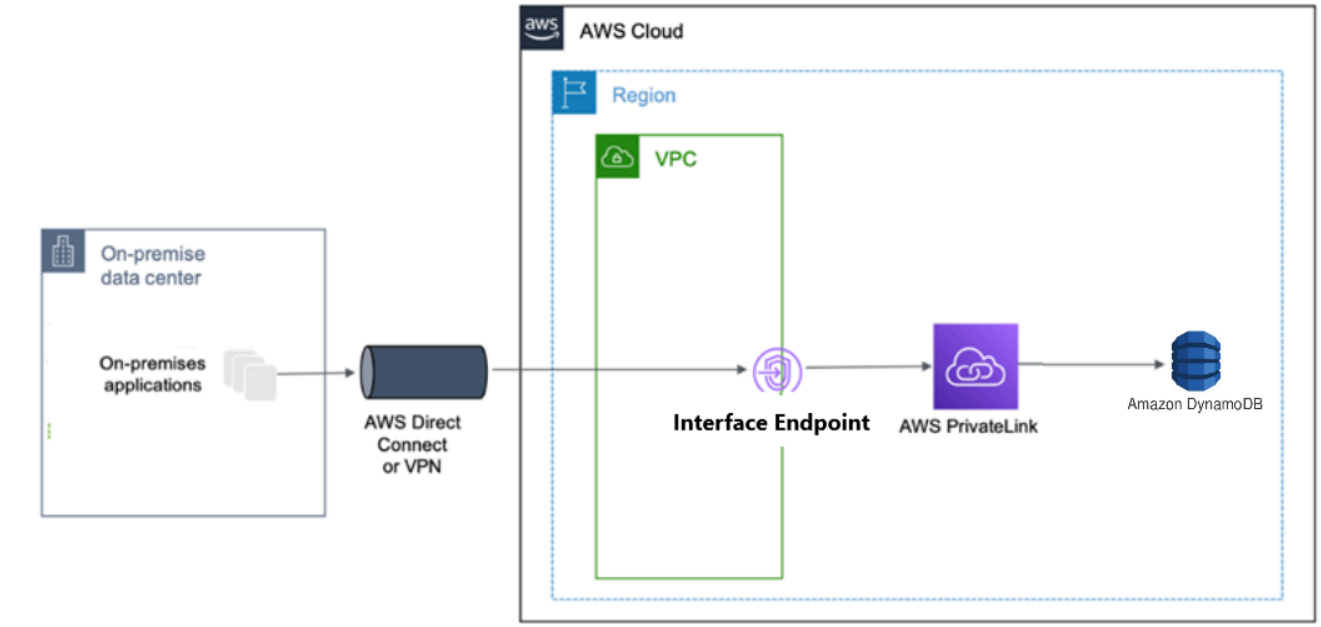
```
.build()
```

Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for DynamoDB, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public DynamoDB DNS domain.

Using interface endpoints to access DynamoDB without a gateway endpoint or an internet gateway in the Amazon VPC

Interface endpoints in your Amazon VPC can route both in-Amazon VPC applications and on-premises applications to DynamoDB over the Amazon network, as illustrated in the following diagram.



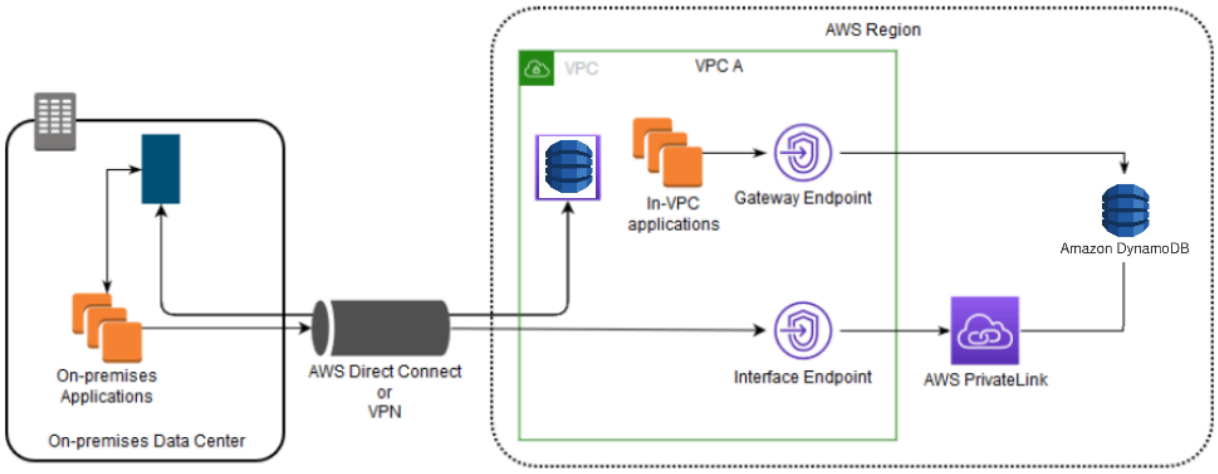
The diagram illustrates the following:

- Your on-premises network uses Direct Connect or Site-to-Site VPN to connect to Amazon VPC A.
- Your applications on-premises and in Amazon VPC A use endpoint-specific DNS names to access DynamoDB through the DynamoDB interface endpoint.

- On-premises applications send data to the interface endpoint in the Amazon VPC through Direct Connect (or Site-to-Site VPN). AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.
- In-Amazon VPC applications also send traffic to the interface endpoint. AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.

Using gateway endpoints and interface endpoints together in the same Amazon VPC to access DynamoDB

You can create interface endpoints and retain the existing gateway endpoint in the same Amazon VPC, as the following diagram shows. By taking this approach, you allow in-Amazon VPC applications to continue accessing DynamoDB through the gateway endpoint, which is not billed. Then, only your on-premises applications would use interface endpoints to access DynamoDB. To access DynamoDB this way, you must update your on-premises applications to use endpoint-specific DNS names for DynamoDB.



The diagram illustrates the following:

- On-premises applications use endpoint-specific DNS names to send data to the interface endpoint within the Amazon VPC through Direct Connect (or Site-to-Site VPN). AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.
- Using default Regional DynamoDB names, in-Amazon VPC applications send data to the gateway endpoint that connects to DynamoDB over the AWS network.

For more information about gateway endpoints, see Gateway Amazon VPC endpoints in the *Amazon VPC User Guide*.

Creating an Amazon VPC endpoint policy for DynamoDB

You can attach an endpoint policy to your Amazon VPC endpoint that controls access to DynamoDB. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

Topics

- Example: Restricting access to a specific table from an Amazon VPC endpoint

Example: Restricting access to a specific table from an Amazon VPC endpoint

You can create an endpoint policy that restricts access to only specific DynamoDB tables. This type of policy is useful if you have other AWS services in your Amazon VPC that use tables. The following table policy restricts access to only the *DOC-EXAMPLE-TABLE*. To use this endpoint policy, replace *DOC-EXAMPLE-TABLE* with the name of your table.

JSON

```
{
"Version":"2012-10-17",
  "Id": "Policy1216114807515",
  "Statement": [
    { "Sid": "Access-to-specific-table-only",
      "Principal": "*",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:PutItem"
      ],
      "Effect": "Allow",
      "Resource": ["arn:aws:dynamodb:us-east-1:111122223333:table/DOC-EXAMPLE-
TABLE",
                   "arn:aws:dynamodb:us-east-1:111122223333:table/DOC-EXAMPLE-
TABLE/*"]
```

```
    }
  ]
}
```

Using DynamoDB endpoints with AWS Management Console Private Access

You must set up DNS configuration for DynamoDB and DynamoDB Streams when using VPC endpoints with the DynamoDB console in AWS Management Console Private Access.

To configure DynamoDB to be accessible in AWS Management Console Private Access, you must create the following two VPC endpoints:

- `com.amazonaws.<region>.dynamodb`
- `com.amazonaws.<region>.dynamodb-streams`

When you create the VPC endpoints, navitage to the Route53 console and create a private hosted zone for DynamoDB using the regional endpoint `dynamodb.us-east-1.amazonaws.com`.

Create the following two alias records in the private hosted zone:

- `dynamodb.<region>.amazonaws.com` that routes traffic to the VPC endpoint `com.amazonaws.<region>.dynamodb`.
- `streams.dynamodb.<region>.amazonaws.com` that routes traffic to the VPC endpoint `com.amazonaws.<region>.dynamodb-streams`.

AWS PrivateLink for DynamoDB Streams

With AWS PrivateLink for Amazon DynamoDB Streams, you can provision interface Amazon VPC endpoints (interface endpoints) in your virtual private cloud (Amazon VPC). These endpoints are directly accessible from applications that are on premises over VPN and Direct Connect, or in a different AWS Region over Amazon VPC peering. Using AWS PrivateLink and interface endpoints, you can simplify private network connectivity from your applications to DynamoDB Streams.

Applications in your Amazon VPC do not need public IP addresses to communicate with DynamoDB Streams using Amazon VPC interface endpoints for DynamoDB Streams operations. Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned

private IP addresses from subnets in your Amazon VPC. Requests to DynamoDB Streams over interface endpoints stay on the Amazon network. You can also access interface endpoints in your Amazon VPC from on-premises applications through Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your AWS Virtual Private Network with your on-premises network, see the *Direct Connect User Guide* and the *AWS Site-to-Site VPN User Guide*.

For general information about interface endpoints, see Interface Amazon VPC endpoints (AWS PrivateLink).

> **Note**
>
> Only interface endpoints are supported for DynamoDB Streams. Gateway endpoints are not supported.

Topics

- Considerations when using AWS PrivateLink for Amazon DynamoDB Streams
- Creating an Amazon VPC endpoint
- Accessing Amazon DynamoDB Streams interface endpoints
- Accessing DynamoDB Streams API operations from DynamoDB Streams interface endpoints
- AWS SDK examples
- Creating an Amazon VPC endpoint policy for DynamoDB Streams
- Using DynamoDB endpoints with AWS Management Console Private Access

Considerations when using AWS PrivateLink for Amazon DynamoDB Streams

Amazon VPC considerations apply to AWS PrivateLink for Amazon DynamoDB Streams. For more information, see interface endpoint considerations and AWS PrivateLink quotas. The following restrictions apply.

AWS PrivateLink for Amazon DynamoDB Streams doesn't support the following:

- Transport Layer Security (TLS) 1.1
- Private and Hybrid Domain Name System (DNS) services

Important

Do not create private hosted zones to override DynamoDB Streams endpoint DNS names to route traffic to your interface endpoints. DynamoDB DNS configurations might change over time and custom DNS overrides can cause requests to unexpectedly route over public IP addresses instead of your interface endpoints.
To access DynamoDB Streams through AWS PrivateLink, configure your clients to use the Amazon VPC endpoint URL directly (for example, `https://vpce-1a2b3c4d-5e6f.streams.dynamodb.region.vpce.amazonaws.com`).

Note

Network connectivity timeouts to AWS PrivateLink endpoints are not within the scope of DynamoDB Streams error responses and need to be appropriately handled by your applications connecting to the AWS PrivateLink endpoints.

Creating an Amazon VPC endpoint

To create an Amazon VPC interface endpoint, see Create an Amazon VPC endpoint in the *AWS PrivateLink Guide*.

Accessing Amazon DynamoDB Streams interface endpoints

When you create an interface endpoint, DynamoDB generates two types of endpoint-specific, DynamoDB Streams DNS names: *Regional* and *Zonal*.

- A *Regional* DNS name includes a unique Amazon VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for Amazon VPC endpoint ID *vpce-1a2b3c4d*, the DNS name generated might be similar to *vpce-1a2b3c4d-5e6f*`.streams.dynamodb.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, *vpce-1a2b3c4d-5e6f*`-us-east-1a.streams.dynamodb.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

Accessing DynamoDB Streams API operations from DynamoDB Streams interface endpoints

You can use the AWS CLI or AWS SDKs to access DynamoDB Streams API operations through DynamoDB Streams interface endpoints.

AWS CLI examples

To access DynamoDB Streams or API operations through DynamoDB Streams interface endpoints in AWS CLI commands, use the `--region` and `--endpoint-url` parameters.

Example: Create a VPC endpoint

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name com.amazonaws.us-east-1.dynamodb-streams \
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface \
--security-group-ids client-sg-id
```

Example: Modify a VPC endpoint

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-endpoint-id \
--policy-document policy-document \ #example optional parameter
--add-security-group-ids security-group-ids \ #example optional parameter
# any additional parameters needed, see Privatelink documentation for more details
```

Example: List streams using an endpoint URL

In the following example, replace the Region `us-east-1` and the DNS name of the VPC endpoint ID `vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
aws dynamodbstreams --region us-east-1 –endpoint https://
vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com list-streams
```

AWS SDK examples

To access Amazon DynamoDB Streams API operations through DynamoDB Streams interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then, configure your clients to use an endpoint URL for DynamoDB Streams API operation through DynamoDB Streams interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access a DynamoDB stream

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
ddb_streams_client = session.client(
service_name='dynamodbstreams',
region_name='us-east-1',
endpoint_url='https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-
east-1.vpce.amazonaws.com'
)
```

SDK for Java 1.x

Example: Use an endpoint URL to access a DynamoDB stream

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
//client build with endpoint config
final AmazonDynamoDBStreams dynamodbstreams =
 AmazonDynamoDBStreamsClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-
east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
```

SDK for Java 2.x

Example: Use an endpoint URL to access DynamoDB stream

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
Region region = Region.US_EAST_1;
dynamoDbStreamsClient = DynamoDbStreamsClient.builder().region(region)
.endpointOverride(URI.create("https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-
east-1.vpce.amazonaws.com"))
.build()
```

Creating an Amazon VPC endpoint policy for DynamoDB Streams

You can attach an endpoint policy to your Amazon VPC endpoint that controls access to DynamoDB Streams. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

Topics

- Example: Restricting access to a specific stream from an Amazon VPC endpoint

Example: Restricting access to a specific stream from an Amazon VPC endpoint

You can create an endpoint policy that restricts access to only specific DynamoDB Streams. This type of policy is useful if you have other AWS services in your Amazon VPC that use DynamoDB Streams. The following stream policy restricts access to only the stream *2025-02-20T11:22:33.444* attached to *DOC-EXAMPLE-TABLE*. To use this endpoint policy, replace *DOC-EXAMPLE-TABLE* with the name of your table and *2025-02-20T11:22:33.444* with the stream label.

JSON

```
{
```

```
"Version":"2012-10-17",
  "Id": "Policy1216114807515",
  "Statement": [
    { "Sid": "Access-to-specific-stream-only",
      "Principal": "*",
      "Action": [
        "dynamodb:DescribeStream",
        "dynamodb:GetRecords"
      ],
      "Effect": "Allow",
      "Resource": ["arn:aws:dynamodb:us-east-1:111122223333:table/table-name/
stream/2025-02-20T11:22:33.444"]
    }
  ]
}
```

> **Note**
>
> Gateway endpoints aren't supported in DynamoDB Streams.

Using DynamoDB endpoints with AWS Management Console Private Access

You must set up DNS configuration for DynamoDB and DynamoDB Streams when using VPC endpoints with the DynamoDB console in AWS Management Console Private Access.

To configure DynamoDB to be accessible in AWS Management Console Private Access, you must create the following two VPC endpoints:

- `com.amazonaws.<region>.dynamodb`
- `com.amazonaws.<region>.dynamodb-streams`

When you create the VPC endpoints, navitage to the Route53 console and create a private hosted zone for DynamoDB using the regional endpoint `dynamodb.us-east-1.amazonaws.com`.

Create the following two alias records in the private hosted zone:

- `dynamodb.<region>.amazonaws.com` that routes traffic to the VPC endpoint `com.amazonaws.<region>.dynamodb`.

- `streams.dynamodb.<region>.amazonaws.com` that routes traffic to the VPC endpoint `com.amazonaws.<region>.dynamodb-streams`.

Using AWS PrivateLink for DynamoDB Accelerator (DAX)

AWS PrivateLink for DynamoDB Accelerator (DAX) enables you to securely access DAX management APIs such as `CreateCluster`, `DescribeClusters`, and `DeleteCluster` over private IP addresses within your virtual private cloud (VPC). This feature enables you to access DAX services privately from your applications without exposing traffic to the public internet.

DAX PrivateLink supports dual-stack endpoints (`dax.{region}.api.aws`), enabling both IPv4 and IPv6 connectivity. With AWS PrivateLink for DAX, customers can access the service using private DNS names. The dual-stack endpoint support ensures transparent connectivity while maintaining network privacy. This allows you to access DAX through both public internet and VPC endpoints without making any changes to your SDK configuration.

Considerations when using AWS PrivateLink for DynamoDB Accelerator (DAX)

When implementing AWS PrivateLink for DynamoDB Accelerator (DAX), several important considerations must be taken into account.

Before you set up an interface endpoint for DAX consider the following:

- DAX interface endpoints only support access to the DAX management APIs within the same AWS Region. You can't use an interface endpoint to access DAX management APIs in other Regions.
- To access the AWS Management Console privately for DAX management, you may need to create additional VPC endpoints for services like `com.amazonaws.region.console` and related services.
- You are charged for creating and using an interface endpoint to DAX. For pricing information, see AWS PrivateLink pricing.

How AWS PrivateLink works with DAX

When you create an interface endpoint for DAX:

1. AWS creates an endpoint network interface in each subnet you enable for the interface endpoint.

2. These are requester-managed network interfaces that serve as entry points for traffic destined for DAX.
3. You can then access DAX through private IP addresses within your VPC.
4. This architecture allows you to use VPC security groups to manage access to the endpoints.
5. Applications can access both DynamoDB and DAX through their respective interface endpoints within a VPC, while also allowing on-premises applications to connect through Direct Connect or VPN.
6. This provides a consistent connectivity model across both services, simplifies architecture, and improves security by keeping traffic within the AWS network.

Creating Interface Endpoints for DAX

You can create an interface endpoint to connect to DAX using the AWS Management Console, AWS SDK, CloudFormation, or the AWS API.

To create an interface endpoint for DAX using the console

1. Navigate to the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create Endpoint**.
4. For **Service category**, choose **AWS services** and for **Service Name**, search for and select `com.amazonaws.region.dax`.
5. For **VPC**, select the VPC from which you want to access DAX and for **Subnets**, select the subnets where AWS will create the endpoint network interfaces.
6. For **Security groups**, select or create security groups to associate with the endpoint network interfaces.
7. For **Policy**, keep the default **Full Access** or customize as needed.
8. Select **Enable DNS Name** to enable private DNS for the endpoint. Keep the private DNS name enabled to prevent changes in the SDK configuration. When enabled, your applications can continue using the standard service DNS name (example: `dax.region.amazonaws.com`). AWS creates a private hosted zone in your VPC that resolves this name to your endpoint's private IP address.

> **Note**
>
> Use Regional DNS names if required. Using zonal DNS names isn't recommended. Also, select subnets from 3 or more AZs to ensure maximum availability through PrivateLink.

9. Choose **Create endpoint**.

To create an interface endpoint for DAX using the AWS CLI

Use the `create-vpc-endpoint` command with the `vpc-endpoint-type` parameter set to `Interface` and the `service-name` parameter set to `com.amazonaws.region.dax`.

```
aws ec2 create-vpc-endpoint \
    --vpc-id vpc-ec43eb89 \
    --vpc-endpoint-type Interface \
    --service-name com.amazonaws.us-east-1.dax \
    --subnet-ids subnet-abcd1234 subnet-1a2b3c4d \
    --security-group-ids sg-1a2b3c4d \
    --private-dns-enabled
```

Additional resources

For more information about AWS PrivateLink and VPC endpoints, see the following resources:

Configuration and vulnerability analysis in Amazon DynamoDB

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- Compliance validation for Amazon DynamoDB

- Shared responsibility model
- Amazon Web Services: Overview of security processes(whitepaper)

The following security best practices also address configuration and vulnerability analysis in Amazon DynamoDB:

- Monitor DynamoDB compliance with AWS Config Rules
- Monitor DynamoDB configuration with AWS Config

Security best practices for Amazon DynamoDB

Amazon DynamoDB provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

Topics

- DynamoDB preventative security best practices
- DynamoDB detective security best practices

DynamoDB preventative security best practices

The following best practices can help you anticipate and prevent security incidents in Amazon DynamoDB.

Encryption at rest

DynamoDB encrypts at rest all user data stored in tables, indexes, streams, and backups using encryption keys stored in AWS Key Management Service (AWS KMS). This provides an additional layer of data protection by securing your data from unauthorized access to the underlying storage.

You can specify whether DynamoDB should use an AWS owned key (default encryption type), an AWS managed key, or a customer managed key to encrypt user data. For more information, see Amazon DynamoDB Encryption at Rest.

Use IAM roles to authenticate access to DynamoDB

For users, applications, and other AWS services to access DynamoDB, they must include valid AWS credentials in their AWS API requests. We recommend that you do not store AWS credentials directly in the application or EC2 instance. These are long-term credentials that are not automatically rotated, and therefore could have significant business impact if they are compromised. An IAM role enables you to obtain temporary access keys that can be used to access AWS services and resources.

For more information, see Identity and Access Management for Amazon DynamoDB.

Use IAM policies for DynamoDB base authorization

When granting permissions, you decide who is getting them, which DynamoDB APIs they are getting permissions for, and the specific actions you want to allow on those resources. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

Attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on DynamoDB resources.

You can do this by using the following:

- AWS Managed (predefined) policies
- Customer managed policies

Use IAM policy conditions for fine-grained access control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

You can specify conditions when granting permissions using an IAM policy. For example, you can do the following:

- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

For more information, see Using IAM Policy Conditions for Fine-Grained Access Control.

Use a VPC endpoint and policies to access DynamoDB

If you only require access to DynamoDB from within a virtual private cloud (VPC), we recommend using a VPC endpoint to limit access from only the required VPC. Doing this prevents that traffic from traversing the open internet and being subject to that environment.

Using a VPC endpoint for DynamoDB allows you to control and limit access using the following:

- VPC endpoint policies – These policies are applied on the DynamoDB VPC endpoint. They allow you to control and limit API access to the DynamoDB table.
- IAM policies – By using the `aws:sourceVpce` condition on policies attached to users, groups, or roles, you can enforce that all access to the DynamoDB table is through the specified VPC endpoint.

For more information, see Endpoints for Amazon DynamoDB.

Consider client-side encryption

We recommend that you plan your encryption strategy before implementing your table in DynamoDB. If you store sensitive or confidential data in DynamoDB, consider including client-side encryption in your plan. This way you can encrypt data as close as possible to its origin, and make sure that it is protected throughout its lifecycle. Encrypting your sensitive data in transit and at rest helps make sure that your plaintext data isn't available to any third party.

The AWS Database Encryption SDK for DynamoDB is a software library that helps you protect your table data before you send it to DynamoDB. It encrypts, signs, verifies, and decrypts your DynamoDB table items. You control which attributes are encrypted and signed.

Primary Key considerations

Do not use sensitive names or sensitive plaintext data in your Primary Key for your table and Global Secondary Indexes. Key names will show up in your table definition. For example, the Primary Key names are accessible to anyone with permissions to call DescribeTable. Key values can show up in your AWS CloudTrail and other logs. Additionally, DynamoDB uses the key values to distribute data and route requests and AWS administrators might observe the values to maintain the health of the service.

If you need to use sensitive data in your table or GSI key values, we recommend using end-to-end client encryption. With end-to-end client encryption, you can perform key-value references to your data while making sure that it never appears unencrypted in your DynamoDB related logs. One way to accomplish this is to use the AWS Database Encryption SDK for DynamoDB,

but that is not required. If you use your own solution, always use a sufficiently secure encryption algorithm. You must not use a non-cryptographic option like a hash, as they are not considered sufficiently secure in most situations.

If your Primary Key key names are sensitive, we recommend using `pk` and `sk` instead. This is a general best practice which leaves your Partition Key design flexible.

Always consult your security experts or AWS account team if you are concerned about what the right choice would be.

DynamoDB detective security best practices

The following best practices for Amazon DynamoDB can help you detect potential security weaknesses and incidents.

Use AWS CloudTrail to monitor AWS managed KMS key usage

If you are using an AWS managed key for encryption at rest, usage of this key is logged into AWS CloudTrail. CloudTrail provides visibility into user activity by recording actions taken on your account. CloudTrail records important information about each action, including who made the request, the services used, the actions performed, parameters for the actions, and the response elements returned by the AWS service. This information helps you track changes made to your AWS resources and troubleshoot operational issues. CloudTrail makes it easier to ensure compliance with internal policies and regulatory standards.

You can use CloudTrail to audit key usage. CloudTrail creates log files that contain a history of AWS API calls and related events for your account. These log files include all AWS KMS API requests made using the AWS Management Console, AWS SDKs, and command line tools, in addition to those made through integrated AWS services. You can use these log files to get information about when the KMS key was used, the operation that was requested, the identity of the requester, the IP address that the request came from, and so on. For more information, see Logging AWS KMS API Calls with AWS CloudTrail and the AWS CloudTrail User Guide.

Monitor DynamoDB operations using CloudTrail

CloudTrail can monitor both control plane events and data plane events. Control plane operations let you create and manage DynamoDB tables. They also let you work with indexes, streams, and other objects that are dependent on tables. Data plane operations let you perform create, read, update, and delete (also called *CRUD*) actions on data in a table. Some data plane

operations also let you read data from a secondary index. To enable logging of data plane events in CloudTrail, you must enable logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

When activity occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events in the event history. For more information, see Logging DynamoDB Operations by Using AWS CloudTrail. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in the *AWS CloudTrail User Guide*.

For an ongoing record of events in your AWS account, including events for DynamoDB, create a trail. A trail enables CloudTrail to deliver log files to an Amazon Simple Storage Service (Amazon S3) bucket. By default, when you create a trail on the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs.

Use DynamoDB Streams to monitor data plane operations

DynamoDB is integrated with AWS Lambda so that you can create triggers—pieces of code that automatically respond to events in DynamoDB Streams. With triggers, you can build applications that react to data modifications in DynamoDB tables.

If you enable DynamoDB Streams on a table, you can associate the stream Amazon Resource Name (ARN) with a Lambda function that you write. Immediately after an item in the table is modified, a new record appears in the table's stream. AWS Lambda polls the stream and invokes your Lambda function synchronously when it detects new stream records. The Lambda function can perform any actions that you specify, such as sending a notification or initiating a workflow.

For an example, see Tutorial: Using AWS Lambda with Amazon DynamoDB Streams. This example receives a DynamoDB event input, processes the messages that it contains, and writes some of the incoming event data to Amazon CloudWatch Logs.

Monitor DynamoDB configuration with AWS Config

Using AWS Config, you can continuously monitor and record configuration changes of your AWS resources. You can also use AWS Config to inventory your AWS resources. When a change from a previous state is detected, an Amazon Simple Notification Service (Amazon SNS) notification can be delivered for you to review and take action. Follow the guidance in Setting Up AWS Config with the Console, ensuring that DynamoDB resource types are included.

You can configure AWS Config to stream configuration changes and notifications to an Amazon SNS topic. For example, when a resource is updated, you can get a notification sent to your email, so that you can view the changes. You can also be notified when AWS Config evaluates your custom or managed rules against your resources.

For an example, see Notifications that AWS Config Sends to an Amazon SNS topic in the *AWS Config Developer Guide*.

Monitor DynamoDB compliance with AWS Config rules

AWS Config continuously tracks the configuration changes that occur among your resources. It checks whether these changes violate any of the conditions in your rules. If a resource violates a rule, AWS Config flags the resource and the rule as noncompliant.

By using AWS Config to evaluate your resource configurations, you can assess how well your resource configurations comply with internal practices, industry guidelines, and regulations. AWS Config provides AWS managed rules, which are predefined, customizable rules that AWS Config uses to evaluate whether your AWS resources comply with common best practices.

Tag your DynamoDB resources for identification and automation

You can assign metadata to your AWS resources in the form of tags. Each tag is a simple label consisting of a customer-defined key and an optional value that can make it easier to manage, search for, and filter resources.

Tagging allows for grouped controls to be implemented. Although there are no inherent types of tags, they enable you to categorize resources by purpose, owner, environment, or other criteria. The following are some examples:

- Security – Used to determine requirements such as encryption.
- Confidentiality – An identifier for the specific data-confidentiality level a resource supports.
- Environment – Used to distinguish between development, test, and production infrastructure.

For more information, see AWS Tagging Strategies and Tagging for DynamoDB.

Monitor your usage of Amazon DynamoDB as it relates to security best practices by using AWS Security Hub CSPM.

Security Hub CSPM uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks.

For more information about using Security Hub CSPM to evaluate DynamoDB resources, see Amazon DynamoDB controls in the *AWS Security Hub CSPM User Guide*.

Monitoring and logging in DynamoDB

Monitoring is an important part of maintaining the reliability, availability, and performance of DynamoDB and your AWS solutions. You should collect monitoring data from all parts of your AWS solutions so you can easily debug a multi-point failure.

Topics

- Monitoring plan
- Performance baseline
- Integrated services
- Automated monitoring tools
- Monitoring metrics in DynamoDB with Amazon CloudWatch
- Logging DynamoDB operations by using AWS CloudTrail
- Analyzing data access using CloudWatch contributor insights for DynamoDB

Monitoring plan

Before you start monitoring DynamoDB, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

Performance baseline

Establish a baseline for normal DynamoDB performance in your environment, by measuring performance at various times and under different load conditions. As you monitor DynamoDB, you should consider storing historical monitoring data. This stored data will give you a baseline from which to compare current performance data, identify normal performance patterns and

performance anomalies, and devise methods to address issues. To establish a baseline you should, at a minimum, monitor the following items:

- The number of read or write capacity units consumed over the specified time period, so you can track how much of your provisioned throughput is used.
- Requests that exceeded a table's provisioned write or read capacity during the specified time period, so you can determine which requests exceed the provisioned throughput quotas of a table.
- System errors, so you can determine if any requests resulted in an error.

Integrated services

DynamoDB automatically monitors your tables on your behalf and reports metrics through Amazon CloudWatch. Additionally, DynamoDB integrates with the following AWS services to help you monitor and troubleshoot your DynamoDB resources.

- AWS CloudTrail captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see Logging DynamoDB operations by using AWS CloudTrail.
- Contributor Insights is a diagnostic tool for identifying the most frequently accessed and throttled keys in your table or index at a glance. For more information, see Analyzing data access using CloudWatch contributor insights for DynamoDB.

Automated monitoring tools

AWS provides various tools that you can use to monitor DynamoDB. We recommend that you automate monitoring tasks as much as possible. You can use the following automated monitoring tools to watch DynamoDB and report when something is wrong:

- **Amazon CloudWatch alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods.

  The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. Amazon CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a

specified number of periods. For more information, see Monitoring metrics in DynamoDB with Amazon CloudWatch.

- **AWS CloudTrail log monitoring** – Share log files between accounts, monitor AWS CloudTrail log files in real time by sending them to AWS CloudTrail Logs, write log processing applications in Java, and validate that your log files haven't changed after delivery by AWS CloudTrail. For more information, see What is Amazon CloudWatch Logs in the *AWS CloudTrail User Guide*.

Monitoring metrics in DynamoDB with Amazon CloudWatch

You can monitor DynamoDB using CloudWatch, which collects and processes raw data from DynamoDB into readable, near real-time metrics. These statistics are retained for a period of time, so you can access historical information for a better perspective on how your web application or service is performing. By default, DynamoDB metric data is sent to CloudWatch automatically. For more information, see What is Amazon CloudWatch? and Metrics retention in the *Amazon CloudWatch User Guide*.

How do I use DynamoDB metrics?

The metrics reported by DynamoDB provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, not a comprehensive list.

How do I use DynamoDB metrics?

How can I?	Relevant metrics
How can I monitor the rate of TTL deletions on my table?	You can monitor `TimeToLiveDeletedItemCount` over the specified time period, to track the rate of TTL deletions on your table. For an example of a server-less application using the

How can I?	Relevant metrics
	`TimeToLiveDeletedItemCount` metric, see Automatically archive items to S3 using DynamoDB time to live (TTL) with AWS Lambda and Amazon Data Firehose.
How can I determine how much of my provisioned throughput is being used?	You can monitor `ConsumedReadCapacityUnits` or `ConsumedWriteCapacityUnits` over the specified time period, to track how much of your provisioned throughput is being used.
How can I determine which requests exceed the provisioned throughput quotas of a table?	`ThrottledRequests` is incremented by one if any event within a request exceeds a provisioned throughput quota. Then, to gain insight into which event is throttling a request, compare `ThrottledRequests` with the `ReadThrottleEvents` and `WriteThrottleEvents` metrics for the table and its indexes.
How can I determine if any system errors occurred?	You can monitor `SystemErrors` to determine if any requests resulted in an HTTP 500 (server error) code. In a distributed system such as DynamoDB, occasional HTTP 500 errors are expected, and you can retry the affected request. If system errors persist over a prolonged period, contact AWS Support at https://aws.amazon.com/support.
How can I monitor the latency value for my table operations?	You can monitor `SuccessfulRequestLatency` by tracking the average latency and median latency through percentile metrics (p50). Occasional spikes in latency aren't a cause for concern. However, if average latency or p50 (median) is high, there could be an underlying issue that you must resolve. See Troubleshooting latency issues in Amazon DynamoDB for more information.

Viewing metrics in the CloudWatch console

Metrics are grouped by the service namespace first and then by the various dimension combinations within each namespace.

To view metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics, All metrics**.
3. Select the **DynamoDB** namespace. You can also select **Usage** namespace to view DynamoDB usage metrics. For more information about usage metrics, see AWS usage metrics.
4. The **Browse** tab displays all metrics in the namespace.
5. (Optional) To add the metric graph to a CloudWatch dashboard, choose **Actions, Add to dashboard**.

Viewing metrics in the AWS CLI

To obtain metric information using the AWS CLI, use the CloudWatch command `list-metrics`. In the following example, you list all metrics in the `AWS/DynamoDB` namespace.

```
aws cloudwatch list-metrics --namespace "AWS/DynamoDB"
```

To obtain metric statistics, use the command `get-metric-statistics`. The following command gets `ConsumedReadCapacityUnits` statistics for the table `ProductCatalog` over the specific 24-hour period, with a 5-minute granularity.

```
aws cloudwatch get-metric-statistics –namespace AWS/DynamoDB \
     –metric-name ConsumedReadCapacityUnits \
     –start-time 2023-11-01T00:00:00Z \
     –end-time 2023-11-02T00:00:00Z \
     –period 360 \
     –statistics Average \
     –dimensions Name=TableName,Value=ProductCatalog
```

Sample output appears as follows:

```
{
    "Datapoints": [
        {
            "Timestamp": "2023-11-01T 09:18:00+00:00",
```

```
            "Average": 20,
            "Unit": "Count"
        },
        {
            "Timestamp": "2023-11-01T 04:36:00+00:00",
            "Average": 22.5,
            "Unit": "Count"
        },
        {
            "Timestamp": "2023-11-01T 15:12:00+00:00",
            "Average": 20,
            "Unit": "Count"
        }, ...
        {
            "Timestamp": "2023-11-01T 17:30:00+00:00",
            "Average": 25,
            "Unit": "Count"
        }
    ],
    "Label": " ConsumedReadCapacityUnits "
}
```

DynamoDB Metrics and dimensions

When you interact with DynamoDB, it sends metrics and dimensions to CloudWatch.

DynamoDB outputs consumed provisioned throughput for one-minute periods. Auto scaling triggers when your consumed capacity breaches the configured target utilization for two consecutive minutes. CloudWatch alarms might have a short delay of up to a few minutes before triggering auto scaling. This delay ensures accurate CloudWatch metric evaluation. If the consumed throughput spikes are more than a minute apart, auto scaling might not trigger. Similarly, a scale down event can occur when 15 consecutive data points are lower than the target utilization. In either case, after auto scaling triggers, the UpdateTable API is invoked. It then takes several minutes to update the provisioned capacity for the table or index. During this period, any requests that exceed the previous provisioned capacity of the tables are throttled.

Viewing metrics and dimensions

CloudWatch displays the following metrics for DynamoDB:

DynamoDB metrics

Note

Amazon CloudWatch aggregates these metrics at one-minute intervals:

- ConditionalCheckFailedRequests
- ConsumedReadCapacityUnits
- ConsumedWriteCapacityUnits
- ReadAccountLimitThrottleEvents
- ReadKeyRangeThroughputThrottleEvents
- ReadMaxOnDemandThroughputThrottleEvents
- ReadProvisionedThroughputThrottleEvents
- ReadThrottleEvents
- ReturnedBytes
- ReturnedItemCount
- ReturnedRecordsCount
- SuccessfulRequestLatency
- SystemErrors
- TimeToLiveDeletedItemCount
- ThrottledRequests
- TransactionConflict
- UserErrors
- WriteAccountLimitThrottleEvents
- WriteKeyRangeThroughputThrottleEvents
- WriteMaxOnDemandThroughputThrottleEvents
- WriteProvisionedThroughputThrottleEvents
- WriteThrottleEvents
- FaultInjectionServiceInducedErrors

For all other DynamoDB metrics, the aggregation granularity is five minutes.

Not all statistics, such as *Average* or *Sum*, are applicable for every metric. However, all of these values are available through the Amazon DynamoDB console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics.

In the following list, each metric has a set of valid statistics that are applicable to that metric.

List of Available Metrics

- AccountMaxReads
- AccountMaxTableLevelReads
- AccountMaxTableLevelWrites
- AccountMaxWrites
- AccountProvisionedReadCapacityUtilization
- AccountProvisionedWriteCapacityUtilization
- AgeOfOldestUnreplicatedRecord
- ConditionalCheckFailedRequests
- ConsumedChangeDataCaptureUnits
- ConsumedReadCapacityUnits
- ConsumedWriteCapacityUnits
- FailedToReplicateRecordCount
- MaxProvisionedTableReadCapacityUtilization
- MaxProvisionedTableWriteCapacityUtilization
- OnDemandMaxReadRequestUnits
- OnDemandMaxWriteRequestUnits
- OnlineIndexConsumedWriteCapacity
- OnlineIndexPercentageProgress
- OnlineIndexThrottleEvents
- PendingReplicationCount
- ProvisionedReadCapacityUnits
- ProvisionedWriteCapacityUnits
- ReadAccountLimitThrottleEvents
- ReadKeyRangeThroughputThrottleEvents

- ReadMaxOnDemandThroughputThrottleEvents
- ReadProvisionedThroughputThrottleEvents
- ReadThrottleEvents
- ReplicationLatency
- ReturnedBytes
- ReturnedItemCount
- ReturnedRecordsCount
- SuccessfulRequestLatency
- SystemErrors
- TimeToLiveDeletedItemCount
- ThrottledPutRecordCount
- ThrottledRequests
- TransactionConflict
- UserErrors
- WriteAccountLimitThrottleEvents
- WriteKeyRangeThroughputThrottleEvents
- WriteMaxOnDemandThroughputThrottleEvents
- WriteProvisionedThroughputThrottleEvents
- WriteThrottleEvents
- Usage metrics
- FaultInjectionServiceInducedErrors
- VectorSearchRequestBytes
- VectorWriteRequestBytes

AccountMaxReads

The maximum number of read capacity units that can be used by an account. This limit doesn't apply to on-demand tables or global secondary indexes.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of read capacity units that can be used by an account.

AccountMaxTableLevelReads

The maximum number of read capacity units that can be used by a table or global secondary index of an account. For on-demand tables, this limit caps the maximum read request units a table or a global secondary index can use.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of read capacity units that can be used by a table or global secondary index of the account.

AccountMaxTableLevelWrites

The maximum number of write capacity units that can be used by a table or global secondary index of an account. For on-demand tables, this limit caps the maximum write request units a table or a global secondary index can use.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of write capacity units that can be used by a table or global secondary index of the account.

AccountMaxWrites

The maximum number of write capacity units that can be used by an account. This limit doesn't apply to on-demand tables or global secondary indexes.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of write capacity units that can be used by an account.

AccountProvisionedReadCapacityUtilization

The percentage of provisioned read capacity units utilized by an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned read capacity units utilized by the account.
- `Minimum` – The minimum percentage of provisioned read capacity units utilized by the account.
- `Average` – The average percentage of provisioned read capacity units utilized by the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

AccountProvisionedWriteCapacityUtilization

The percentage of provisioned write capacity units utilized by an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned write capacity units utilized by the account.
- `Minimum` – The minimum percentage of provisioned write capacity units utilized by the account.
- `Average` – The average percentage of provisioned write capacity units utilized by the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

AgeOfOldestUnreplicatedRecord

The elapsed time since a record yet to be replicated to the Kinesis data stream first appeared in the DynamoDB table.

Units: `Milliseconds`

Dimensions: `TableName, DelegatedOperation`

Valid Statistics:

- Maximum.
- Minimum.
- Average.

ConditionalCheckFailedRequests

The number of failed attempts to perform conditional writes. The PutItem, UpdateItem, and DeleteItem operations let you provide a logical condition that must evaluate to true before the operation can proceed. If this condition evaluates to false, ConditionalCheckFailedRequests is incremented by one. ConditionalCheckFailedRequests is also incremented by one for PartiQL Update and Delete statements where a logical condition is provided and that condition evaluates to false.

> **Note**
>
> A failed conditional write will result in an HTTP 400 error (Bad Request). These events are reflected in the ConditionalCheckFailedRequests metric, but not in the UserErrors metric.

Units: Count

Dimensions: TableName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

ConsumedChangeDataCaptureUnits

The number of consumed change data capture units.

Units: Count

Dimensions: `TableName, DelegatedOperation`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`

ConsumedReadCapacityUnits

The number of read capacity units consumed over the specified time period for both provisioned and on-demand capacity, so you can track how much of your throughput is used. You can retrieve the total consumed read capacity for a table and all of its global secondary indexes, or for a particular global secondary index. For more information, see Read/Write Capacity Mode.

The `TableName` dimension returns the `ConsumedReadCapacityUnits` for the table, but not for any global secondary indexes. To view `ConsumedReadCapacityUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

> **Note**
>
> This means that short, intense spikes in capacity consumption lasting just a second might not be accurately reflected in the CloudWatch graph, potentially leading to a lower apparent consumption rate for that minute.
> Use the `Sum` statistic to calculate the consumed throughput. For example, get the `Sum` value over a span of one minute, and divide it by the number of seconds in a minute (60) to calculate the average `ConsumedReadCapacityUnits` per second. You can compare the calculated value to the provisioned throughput value that you provide DynamoDB.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum` – The minimum number of read capacity units consumed by any individual request to the table or index.

- `Maximum` – The maximum number of read capacity units consumed by any individual request to the table or index.
- `Average` – The average per-request read capacity consumed.

> **Note**
>
> The `Average` value is influenced by periods of inactivity where the sample value will be zero.

- Sum – The total read capacity units consumed. This is the most useful statistic for the `ConsumedReadCapacityUnits` metric.
- `SampleCount` – represents the frequency at which the metric is emitted. Even tables with zero traffic will have the `SampleCount` emitted regularly, but the sample values will always be zero.

> **Note**
>
> The `SampleCount` value is influenced by periods of inactivity where the sample value will be zero.

ConsumedWriteCapacityUnits

The number of write capacity units consumed over the specified time period for both provisioned and on-demand capacity, so you can track how much of your throughput is used. You can retrieve the total consumed write capacity for a table and all of its global secondary indexes, or for a particular global secondary index. For more information, see Read/Write Capacity Mode.

The `TableName` dimension returns the `ConsumedWriteCapacityUnits` for the table, but not for any global secondary indexes. To view `ConsumedWriteCapacityUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`. The `Source` dimension can return either of two values: `Customer` and `GlobalTable`. Replicated writes will have `ConsumedWriteCapacityUnits` with the source `GlobalTable`, but regional table writes will have `ConsumedWriteCapacityUnits` with the source `Customer`.

> **Note**
>
> Use the Sum statistic to calculate the consumed throughput. For example, get the Sum value over a span of one minute, and divide it by the number of seconds in a minute (60) to

calculate the average `ConsumedWriteCapacityUnits` per second (recognizing that this average doesn't highlight any large but brief spikes in write activity that occurred during that minute). You can compare the calculated value to the provisioned throughput value that you provide DynamoDB.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName, Source`

Valid Statistics:

- `Minimum` – The minimum number of write capacity units consumed by any individual request to the table or index.
- `Maximum` – The maximum number of write capacity units consumed by any individual request to the table or index.
- `Average` – The average per-request write capacity consumed.

> **Note**
>
> The `Average` value is influenced by periods of inactivity where the sample value will be zero.

- Sum – The total write capacity units consumed. This is the most useful statistic for the `ConsumedWriteCapacityUnits` metric.
- `SampleCount` – represents the frequency at which the metric is emitted. Even tables with zero traffic will have the `SampleCount` emitted regularly, but the sample values will always be zero.

> **Note**
>
> The `SampleCount` value is influenced by periods of inactivity where the sample value will be zero.

FailedToReplicateRecordCount

The number of records that DynamoDB failed to replicate to your Kinesis data stream.

Units: `Count`

Dimensions: `TableName`, `DelegatedOperation`

Valid Statistics:

- `Sum`

MaxProvisionedTableReadCapacityUtilization

The percentage of provisioned read capacity utilized by the highest provisioned read table or global secondary index of an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of an account.
- `Minimum` – The minimum percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of an account.
- `Average` – The average percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

MaxProvisionedTableWriteCapacityUtilization

The percentage of provisioned write capacity utilized by the highest provisioned write table or global secondary index of an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of an account.
- `Minimum` – The minimum percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of an account.
- `Average` – The average percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of the account. The metric is published for

five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

OnDemandMaxReadRequestUnits

The number of specified on-demand read request units for a table or a global secondary index.

To view `OnDemandMaxReadRequestUnits` for a table, you must specify `TableName`. To view `OnDemandMaxReadRequestUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

Units: Count

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum` – The lowest setting for on-demand read request units. If you use `UpdateTable` to increase read request units, this metric shows the lowest value of on-demand `ReadRequestUnits` during this time period.
- `Maximum` – The highest setting for on-demand read request units. If you use `UpdateTable` to decrease read request units, this metric shows the highest value of on-demand `ReadRequestUnits` during this time period.
- `Average` – The average on-demand read request units. The `OnDemandMaxReadRequestUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the on-demand read request units, this statistic might not reflect the true average.

OnDemandMaxWriteRequestUnits

The number of specified on-demand write request units for a table or a global secondary index.

To view `OnDemandMaxWriteRequestUnits` for a table, you must specify `TableName`. To view `OnDemandMaxWriteRequestUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum` – The lowest setting for on-demand write request units. If you use `UpdateTable` to increase write request units, this metric shows the lowest value of on-demand `WriteRequestUnits` during this time period.
- `Maximum` – The highest setting for on-demand write request units. If you use `UpdateTable` to decrease write request units, this metric shows the highest value of on-demand `WriteRequestUnits` during this time period.
- `Average` – The average on-demand write request units. The `OnDemandMaxWriteRequestUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the on-demand write request units, this statistic might not reflect the true average.

OnlineIndexConsumedWriteCapacity

This metric is expected to show 0 during index builds. This metric previously showed the number of write capacity units consumed when adding a new global secondary index to a table.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`
- `SampleCount`
- `Sum`

OnlineIndexPercentageProgress

The percentage of completion when a new global secondary index is being added to a table. DynamoDB must first allocate resources for the new index, and then backfill attributes from the table into the index. For large tables, this process might take a long time. You should monitor this statistic to view the relative progress as DynamoDB builds the index.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`
- `SampleCount`
- `Sum`

OnlineIndexThrottleEvents

This metric is expected to show 0 during index builds. This metric previously showed the number of write throttle events that occur when adding a new global secondary index to a table.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`
- `SampleCount`
- `Sum`

PendingReplicationCount

Metric for Global tables version 2017.11.29 (Legacy) (global tables only). The number of item updates that are written to one replica table, but that have not yet been written to another replica in the global table.

Units: `Count`

Dimensions: `TableName, ReceivingRegion`

Valid Statistics:

- `Average`

- Sample Count
- Sum

ProvisionedReadCapacityUnits

The number of provisioned read capacity units for a table or a global secondary index. The TableName dimension returns the ProvisionedReadCapacityUnits for the table, but not for any global secondary indexes. To view ProvisionedReadCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units:Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Minimum – The lowest setting for provisioned read capacity. If you use UpdateTable to increase read capacity, this metric shows the lowest value of provisioned ReadCapacityUnits during this time period.
- Maximum – The highest setting for provisioned read capacity. If you use UpdateTable to decrease read capacity, this metric shows the highest value of provisioned ReadCapacityUnits during this time period.
- Average – The average provisioned read capacity. The ProvisionedReadCapacityUnits metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

ProvisionedWriteCapacityUnits

The number of provisioned write capacity units for a table or a global secondary index.

The TableName dimension returns the ProvisionedWriteCapacityUnits for the table, but not for any global secondary indexes. To view ProvisionedWriteCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- `Minimum` – The lowest setting for provisioned write capacity. If you use `UpdateTable` to increase write capacity, this metric shows the lowest value of provisioned `WriteCapacityUnits` during this time period.
- `Maximum` – The highest setting for provisioned write capacity. If you use `UpdateTable` to decrease write capacity, this metric shows the highest value of provisioned `WriteCapacityUnits` during this time period.
- `Average` – The average provisioned write capacity. The `ProvisionedWriteCapacityUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

ReadAccountLimitThrottleEvents

The number of read requests throttled due to account limits.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- Sum – Total number of throttled events.
- `SampleCount` – Number of throttling occurrences.
- `Minimum` – Minimum number of throttled events in any given sample.
- `Maximum` – Maximum number of throttled events in any given sample.

ReadKeyRangeThroughputThrottleEvents

The number of read requests throttled due to partition limits.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- Sum – Total number of throttled events.
- `SampleCount` – Number of throttling occurrences.
- `Minimum` – Minimum number of throttled events in any given sample.

- `Maximum` – Maximum number of throttled events in any given sample.

ReadMaxOnDemandThroughputThrottleEvents

The number of read requests throttled due to on-demand maximum throughput.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- Sum – Total number of throttled events.
- `SampleCount` – Number of throttling occurrences.
- `Minimum` – Minimum number of throttled events in any given sample.
- `Maximum` – Maximum number of throttled events in any given sample.

ReadProvisionedThroughputThrottleEvents

The number of read requests throttled due to provisioned throughput limits.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- Sum – Total number of throttled events.
- `SampleCount` – Number of throttling occurrences.
- `Minimum` – Minimum number of throttled events in any given sample.
- `Maximum` – Maximum number of throttled events in any given sample.

ReadThrottleEvents

Requests to DynamoDB that exceed the provisioned read capacity units for a table or a global secondary index.

A single request can result in multiple events. For example, a `BatchGetItem` that reads 10 items is processed as 10 `GetItem` events. For each event, `ReadThrottleEvents` is incremented by one

if that event is throttled. The ThrottledRequests metric for the entire BatchGetItem is not incremented unless *all 10* of the GetItem events are throttled.

The TableName dimension returns the ReadThrottleEvents for the table, but not for any global secondary indexes. To view ReadThrottleEvents for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- SampleCount
- Sum

ReplicationLatency

(This metric is for DynamoDB global tables.) The elapsed time between an updated item appearing in the DynamoDB stream for one replica table, and that item appearing in another replica in the global table.

Units: Milliseconds

Dimensions: TableName, ReceivingRegion

Valid Statistics:

- Average
- Minimum
- Maximum

ReturnedBytes

The number of bytes returned by GetRecords operations (Amazon DynamoDB Streams) during the specified time period.

Units: Bytes

Dimensions: Operation, StreamLabel, TableName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

ReturnedItemCount

The number of items returned by Query, Scan or ExecuteStatement (select) operations during the specified time period.

The number of items *returned* is not necessarily the same as the number of items that were evaluated. For example, suppose that you requested a Scan on a table or an index that had 100 items, but specified a FilterExpression that narrowed the results so that only 15 items were returned. In this case, the response from Scan would contain a ScanCount of 100 and a Count of 15 returned items.

Units: Count

Dimensions: TableName, Operation

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

ReturnedRecordsCount

The number of stream records returned by GetRecords operations (Amazon DynamoDB Streams) during the specified time period.

Units: Count

Dimensions: `Operation, StreamLabel, TableName`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`
- `SampleCount`
- `Sum`

SuccessfulRequestLatency

The latency of successful requests to DynamoDB or Amazon DynamoDB Streams during the specified time period. `SuccessfulRequestLatency` can provide two different kinds of information:

- The elapsed time for successful requests (`Minimum`, `Maximum`, `Sum`, `Average`, or `Percentile`).
- The number of successful requests (`SampleCount`).

`SuccessfulRequestLatency` reflects activity only within DynamoDB or Amazon DynamoDB Streams, and doesn't consider network latency or client-side activity.

> **Note**
>
> To analyze custom percentile values (such as p99.9), you can manually enter the desired percentile (e.g., p99.9) in the CloudWatch metric statistic field. This allows you to evaluate latency distributions beyond the default percentiles listed in the dropdown.

Units: `Milliseconds`

Dimensions: `TableName, Operation, StreamLabel`

Valid Statistics:

- `Minimum`
- `Maximum`

- Sum
- Average
- Percentile
- SampleCount

SystemErrors

The requests to DynamoDB or Amazon DynamoDB Streams that generate an HTTP 500 status code during the specified time period. An HTTP 500 usually indicates an internal service error.

> **Note**
>
> When DynamoDB returns a system error (HTTP 500), most AWS SDKs automatically perform a configurable number of retries. If the issue resolves during a retry, your application continues without seeing the error, and you might notice increased client-side perceived latency. If the error persists after all retries, it propagates to your application code.

> **Note**
>
> The HTTP 500 errors that AWS FIS injects during a fault injection experiment are also counted in `SystemErrors`, in addition to being counted in `FaultInjectionServiceInducedErrors`. As a result, alarms on `SystemErrors` fire while an experiment is running. To distinguish experiment-induced errors from organic service errors, compare `SystemErrors` with `FaultInjectionServiceInducedErrors` for the same period.

Units: `Count`

Dimensions: `TableName, Operation`

> **Note**
>
> DynamoDB publishes `SystemErrors` only on the `TableName` and `Operation` dimension pair. It does not publish this metric on `TableName` alone. A CloudWatch alarm that

specifies only the `TableName` dimension never matches data and remains in the `INSUFFICIENT_DATA` state, so specify both `TableName` and `Operation`.

Valid Statistics:

- `Sum`
- `SampleCount`

TimeToLiveDeletedItemCount

The number of items deleted by Time to Live (TTL) during the specified time period. This metric helps you monitor the rate of TTL deletions on your table.

Units: `Count`

Dimensions: TableName

Valid Statistics:

- `Sum`

ThrottledPutRecordCount

The number of records that were throttled by your Kinesis data stream due to insufficient Kinesis Data Streams capacity.

Units: `Count`

Dimensions: TableName, DelegatedOperation

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`
- `SampleCount`

ThrottledRequests

Requests to DynamoDB that exceed the provisioned throughput limits on a resource (such as a table or an index).

`ThrottledRequests` is incremented by one if any event within a request exceeds a provisioned throughput limit. For example, if you update an item in a table with global secondary indexes, there are multiple events—a write to the table, and a write to each index. If one or more of these events are throttled, then `ThrottledRequests` is incremented by one.

> **Note**
>
> In a batch request (`BatchGetItem` or `BatchWriteItem`), `ThrottledRequests` is incremented only if *every* request in the batch is throttled.
> If any individual request within the batch is throttled, one of the following metrics is incremented:
>
> - `ReadThrottleEvents` – For a throttled `GetItem` event within `BatchGetItem`.
> - `WriteThrottleEvents` – For a throttled `PutItem` or `DeleteItem` event within `BatchWriteItem`.

To gain insight into which event is throttling a request, compare `ThrottledRequests` with the `ReadThrottleEvents` and `WriteThrottleEvents` for the table and its indexes.

> **Note**
>
> A throttled request will result in an HTTP 400 status code. All such events are reflected in the `ThrottledRequests` metric, but not in the `UserErrors` metric.

Units: `Count`

Dimensions: `TableName, Operation`

Valid Statistics:

- Sum
- `SampleCount`

TransactionConflict

Rejected item-level requests due to transactional conflicts between concurrent requests on the same items. For more information, see Transaction Conflict Handling in DynamoDB.

Units: Count

Dimensions: TableName

Valid Statistics:

- Sum – The number of rejected item-level requests due to transaction conflicts.

  > **Note**
  >
  > If multiple item-level requests within a call to TransactWriteItems or TransactGetItems were rejected, Sum is incremented by one for each item-level Put, Update, Delete, or Get request.

- SampleCount – The number of rejected requests due to transaction conflicts.

  > **Note**
  >
  > If multiple item-level requests within a call to TransactWriteItems or TransactGetItems are rejected, SampleCount is only incremented by one.

- Min – The minimum number of rejected item-level requests within a call to TransactWriteItems, TransactGetItems, PutItem, UpdateItem, or DeleteItem.
- Max – The maximum number of rejected item-level requests within a call to TransactWriteItems, TransactGetItems, PutItem, UpdateItem, or DeleteItem.
- Average – The average number of rejected item-level requests within a call to TransactWriteItems, TransactGetItems, PutItem, UpdateItem, or DeleteItem.

UserErrors

Requests to DynamoDB or Amazon DynamoDB Streams that generate an HTTP 400 status code during the specified time period. An HTTP 400 usually indicates a client-side error, such as an invalid combination of parameters, an attempt to update a nonexistent table, or an incorrect request signature.

Some examples of exceptions that will log metrics related to `UserErrors` would be:

- `ResourceNotFoundException`
- `ValidationException`
- `TransactionConflict`

All such events are reflected in the `UserErrors` metric, except for the following:

- *ProvisionedThroughputExceededException* – See the `ThrottledRequests` metric in this section.
- *ConditionalCheckFailedException* – See the `ConditionalCheckFailedRequests` metric in this section.

`UserErrors` represents the aggregate of HTTP 400 errors for DynamoDB or Amazon DynamoDB Streams requests for the current AWS Region and the current AWS account.

Units: `Count`

Valid Statistics:

- `Sum`
- `SampleCount`

WriteAccountLimitThrottleEvents

The number of write requests throttled due to account limits.

Units: `Count`

Dimensions: `TableName`

Valid Statistics:

- `Sum` – Total number of throttled events.
- `SampleCount` – Number of throttling occurrences.
- `Minimum` – Minimum number of throttled events in any given sample.
- `Maximum` – Maximum number of throttled events in any given sample.

WriteKeyRangeThroughputThrottleEvents

The number of write requests throttled due to partition limits.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- `Sum` – Total number of throttled events.
- `SampleCount` – Number of throttling occurrences.
- `Minimum` – Minimum number of throttled events in any given sample.
- `Maximum` – Maximum number of throttled events in any given sample.

WriteMaxOnDemandThroughputThrottleEvents

The number of write requests throttled due to on-demand maximum throughput.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- `Sum` – Total number of throttled events.
- `SampleCount` – Number of throttling occurrences.
- `Minimum` – Minimum number of throttled events in any given sample.
- `Maximum` – Maximum number of throttled events in any given sample.

WriteProvisionedThroughputThrottleEvents

The number of write requests throttled due to provisioned throughput limits.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- `Sum` – Total number of throttled events.

- SampleCount – Number of throttling occurrences.
- Minimum – Minimum number of throttled events in any given sample.
- Maximum – Maximum number of throttled events in any given sample.

WriteThrottleEvents

Requests to DynamoDB that exceed the provisioned write capacity units for a table or a global secondary index.

A single request can result in multiple events. For example, a PutItem request on a table with three global secondary indexes would result in four events—the table write, and each of the three index writes. For each event, the WriteThrottleEvents metric is incremented by one if that event is throttled. For single PutItem requests, if any of the events are throttled, ThrottledRequests is also incremented by one. For BatchWriteItem, the ThrottledRequests metric for the entire BatchWriteItem is not incremented unless all of the individual PutItem or DeleteItem events are throttled.

The TableName dimension returns the WriteThrottleEvents for the table, but not for any global secondary indexes. To view WriteThrottleEvents for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Sum
- SampleCount

Usage metrics

Usage metrics in CloudWatch allow you to proactively manage usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch anomaly detection, and configuring alarms that alert you when usage approaches a threshold.

DynamoDB also integrates these usage metrics with Service Quotas. You can use CloudWatch to manage your account's use of your service quotas. For more information, see Visualizing your service quotas and setting alarms

List of Available Usage Metrics

- AccountProvisionedWriteCapacityUnits
- AccountProvisionedReadCapacityUnits
- TableCount

AccountProvisionedWriteCapacityUnits

The sum of write capacity units provisioned for all tables and global secondary indexes of an account.

Units: `Count`

Valid Statistics:

- `Minimum` – The lowest number of provisioned write capacity units during a time period.
- `Maximum` – The highest number of provisioned write capacity units during a time period.
- `Average` - The average number provisioned write capacity units account during a time period.

This metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

AccountProvisionedReadCapacityUnits

The sum of read capacity units provisioned for all tables and global secondary indexes of an account.

Units: `Count`

Valid Statistics:

- `Minimum` – The lowest number of provisioned read capacity units during a time period.
- `Maximum` – The highest number of provisioned read capacity units during a time period.
- `Average` - The average number provisioned read capacity units account during a time period.

This metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

TableCount

The number of active tables of an account.

Units: `Count`

Valid Statistics:

- `Minimum` – The lowest number of tables during a time period.
- `Maximum` – The highest number of tables during a time period.
- `Average` - The average number tables during a time period.

FaultInjectionServiceInducedErrors

The requests to DynamoDB that generate a simulated HTTP 500 status code during the specified time period and during the catchup as a result of AWS FIS experiment.

> **Note**
>
> These errors are a subset of the `SystemErrors` metric: each error that AWS FIS injects is counted in both `FaultInjectionServiceInducedErrors` and `SystemErrors`. Use this metric to identify how much of `SystemErrors` is due to a fault injection experiment rather than to organic service errors.

Units: `Count`

Dimensions: `TableName`, `Operation`

Valid Statistics:

- `Sum`
- `SampleCount`

VectorSearchRequestBytes

The number of bytes processed by `SearchVectors` operations on a vector index over the specified time period. This value scales with the size of the vector data that the search examines and returns, which grows with the number of dimensions in the index.

Units: Bytes

Dimensions: TableName, VectorIndexName

Valid Statistics:

- Minimum
- Maximum
- Average
- Sum
- SampleCount

VectorWriteRequestBytes

The number of bytes processed by write operations (PutItem, UpdateItem, DeleteItem, BatchWriteItem, TransactWriteItems) that replicate data to a vector index over the specified time period. This value scales with the size of the data replicated to the index.

Units: Bytes

Dimensions: TableName, VectorIndexName

Valid Statistics:

- Minimum
- Maximum
- Average
- Sum
- SampleCount

Understanding metrics and dimensions for DynamoDB

The metrics for DynamoDB are qualified by the values for the account, table name, global secondary index name, or operation. You can use the CloudWatch console to retrieve DynamoDB data along any of the dimensions in the table below.

List of Available Dimensions

- DelegatedOperation

- GlobalSecondaryIndexName
- Operation
- OperationType
- Verb
- ReceivingRegion
- Source
- StreamLabel
- TableName

DelegatedOperation

This dimension limits the data to operations DynamoDB performs on your behalf. The following operations are captured:

- Change data capture for Kinesis Data Streams.

GlobalSecondaryIndexName

This dimension limits the data to a global secondary index on a table. If you specify `GlobalSecondaryIndexName`, you must also specify `TableName`.

Operation

This dimension limits the data to one of the following DynamoDB operations:

- `PutItem`
- `DeleteItem`
- `UpdateItem`
- `GetItem`
- `BatchGetItem`
- `Scan`
- `Query`
- `BatchWriteItem`
- `TransactWriteItems`
- `TransactGetItems`

- `ExecuteTransaction`
- `BatchExecuteStatement`
- `ExecuteStatement`

In addition, you can limit the data to the following Amazon DynamoDB Streams operation:

- `GetRecords`

OperationType

This dimension limits the data to one of the following operation types:

- `Read`
- `Write`

This dimension is emitted for `ExecuteTransaction` and `BatchExecuteStatement` requests.

Verb

This dimension limits the data to one of the following DynamoDB PartiQL verbs:

- Insert: `PartiQLInsert`
- Select: `PartiQLSelect`
- Update: `PartiQLUpdate`
- Delete: `PartiQLDelete`

This dimension is emitted for the `ExecuteStatement` operation.

ReceivingRegion

This dimension limits the data to a particular AWS region. It is used with metrics originating from replica tables within a DynamoDB global table.

Source

DynamoDB emits this dimension for the `ConsumedWriteCapacityUnits` metric and lets you distinguish what drives the write capacity consumption. It can have one of the following values:

`Customer`

Write capacity consumed by writes that you make directly to the table (including writes to a replica table in a global table).

`GlobalTable`

Write capacity consumed by global table replication writes that DynamoDB applies to a replica table to keep the replicas in sync.

Use this dimension to separate your own write consumption from global table replication consumption, for example when planning capacity.

StreamLabel

This dimension limits the data to a specific stream label. It is used with metrics originating from Amazon DynamoDB Streams `GetRecords` operations.

TableName

This dimension limits the data to a specific table. This value can be any table name in the current region and the current AWS account.

Creating CloudWatch alarms in DynamoDB

A CloudWatch alarm watches a single metric over a specified time period, and performs one or more specified actions, based on the value of the metric relative to a threshold over time. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy. You can also add alarms to dashboards so you can monitor and receive alerts about your AWS resources and applications across multiple regions. There is no limit to the number of alarms you can create. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For a list of recommended DynamoDB alarms, see Recommended alarms.

> **Note**
>
> You must specify all the required dimensions when creating your CloudWatch alarm, since CloudWatch will not aggregate metrics for a missing dimension. Creating a CloudWatch alarm with a missing dimension will not result in an error, when creating the alarm.

Assume you have a provisioned table with five read capacity units. You want to be notified before you consume the entire provisioned read capacity, so you decide to create a CloudWatch alarm to get notified when the consumed capacity reaches 80% of what you have provisioned for the table. You can create alarms in the CloudWatch console or using the AWS CLI.

Creating an alarm in the CloudWatch console

To create an alarm in the CloudWatch console

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Find the row with the table that you want to monitor and **`ConsumeReadCapacityUnits`** in the **Metric Name** column. Select the check box next to this row and choose **Select metric**.
5. Under **Specify metric and conditions**, for **Statistic** choose **Sum**. Choose a **Period** of **1 minute**.
6. Under **Conditions**, specify the following:
   a. For **Threshold type**, choose **Static**.
   b. For **Whenever `ConsumedReadCapacityUnits` is**, choose **Greater/Equal** and specify the threshold as 240.
7. Choose **Next**.
8. Under **Notification**, choose **`In alarm`** and select an SNS topic to notify when the alarm is in ALARM state.
9. When finished, choose **Next**.
10. Enter a name and description for the alarm and choose **Next**.
11. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Creating an alarm in the AWS CLI

```
aws cloudwatch put-metric-alarm \
    -\-alarm-name ReadCapacityUnitsLimitAlarm \
    -\-alarm-description "Alarm when read capacity reaches 80% of my provisioned read
 capacity" \
    -\-namespace AWS/DynamoDB \
```

```
    -\-metric-name ConsumedReadCapacityUnits \
    -\-dimensions Name=TableName,Value=myTable \
    -\-statistic Sum \
    -\-threshold 240 \
    -\-comparison-operator GreaterThanOrEqualToThreshold \
    -\-period 60 \
    -\-evaluation-periods 1 \
    -\-alarm-actions arn:aws:sns:us-east-1:123456789012:capacity-alarm
```

Test the alarm.

```
aws cloudwatch set-alarm-state -\-alarm-name ReadCapacityUnitsLimitAlarm -\-state-
reason "initializing" -\-state-value OK
```

```
aws cloudwatch set-alarm-state -\-alarm-name ReadCapacityUnitsLimitAlarm -\-state-
reason "initializing" -\-state-value ALARM
```

More AWS CLI examples

The following procedure describes how you're notified if you have requests that exceed the provisioned througput quotas of a table.

1. Create an Amazon SNS topic `arn:aws:sns:us-east-1:123456789012:requests-exceeding-throughput`. For more information, see Set up Amazon Simple Notification Service.
2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
        -\-alarm-name ReadCapacityUnitsLimitAlarm \
        -\-alarm-description "Alarm when read capacity reaches 80% of my
 provisioned read capacity" \
        -\-namespace AWS/DynamoDB \
        -\-metric-name ConsumedReadCapacityUnits \
        -\-dimensions Name=TableName,Value=myTable \
        -\-statistic Sum \
        -\-threshold 240 \
        -\-comparison-operator GreaterThanOrEqualToThreshold \
        -\-period 60 \
        -\-evaluation-periods 1 \
        -\-alarm-actions arn:aws:sns:us-east-1:123456789012:capacity-alarm
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name RequestsExceedingThroughputAlarm --
state-reason "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name RequestsExceedingThroughputAlarm --
state-reason "initializing" --state-value ALARM
```

The following procedure describes how you're notified if you get system errors.

1. Create an Amazon SNS topic `arn:aws:sns:us-east-1:123456789012:notify-on-system-errors`. For more information, see Set up Amazon Simple Notification Service.
2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
    --alarm-name SystemErrorsAlarm \
    --alarm-description "Alarm when system errors occur" \
    --namespace AWS/DynamoDB \
    --metric-name SystemErrors \
    --dimensions Name=TableName,Value=myTable
 Name=Operation,Value=aDynamoDBOperation \
    --statistic Sum \
    --threshold 0 \
    --comparison-operator GreaterThanThreshold \
    --period 60 \
    --unit Count \
    --evaluation-periods 1 \
    --treat-missing-data breaching \
    --alarm-actions arn:aws:sns:us-east-1:123456789012:notify-on-system-errors
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name SystemErrorsAlarm --state-reason
 "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name SystemErrorsAlarm --state-reason
 "initializing" --state-value ALARM
```

Logging DynamoDB operations by using AWS CloudTrail

DynamoDB is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in DynamoDB. CloudTrail captures all API calls for DynamoDB as events. The calls captured include calls from the DynamoDB console and code calls to the DynamoDB API operations, using both PartiQL and the classic API. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for DynamoDB. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to DynamoDB, the IP address from which the request was made, who made the request, when it was made, and additional details.

For robust monitoring and alerting, you can also integrate CloudTrail events with Amazon CloudWatch Logs. To enhance your analysis of DynamoDB service activity and identify changes in activities for an AWS account, you can query AWS CloudTrail logs using Amazon Athena. For example, you can use queries to identify trends and further isolate activity by attributes such as source IP address or user.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User Guide.

Topics

- DynamoDB information in CloudTrail
- Understanding DynamoDB log file entries

DynamoDB information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see Working with CloudTrail Event history.

For an ongoing record of events in your AWS account, including events for DynamoDB, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple regions and Receiving CloudTrail log files from multiple accounts

Control plane events in CloudTrail

The following API actions are logged by default as events in CloudTrail files:

Amazon DynamoDB

- CreateBackup
- CreateGlobalTable
- CreateTable
- DeleteBackup
- DeleteTable
- DescribeBackup
- DescribeContinuousBackups
- DescribeGlobalTable
- DescribeLimits
- DescribeTable
- DescribeTimeToLive
- ListBackups
- ListTables
- ListTagsOfResource
- ListGlobalTables
- RestoreTableFromBackup
- RestoreTableToPointInTime
- TagResource
- UntagResource

- UpdateGlobalTable
- UpdateTable
- UpdateTimeToLive
- DescribeReservedCapacity
- DescribeReservedCapacityOfferings
- PurchaseReservedCapacityOfferings
- DescribeScalableTargets
- RegisterScalableTarget

DynamoDB Streams

- DescribeStream
- ListStreams

DynamoDB Accelerator (DAX)

- CreateParameterGroup
- CreateSubnetGroup
- DecreaseReplicationFactor
- DeleteCluster
- DeleteParameterGroup
- DeleteSubnetGroup
- DescribeClusters
- DescribeDefaultParameters
- DescribeEvents
- DescribeParameterGroups
- DescribeParameters
- DescribeSubnetGroups
- IncreaseReplicationFactor

- ListTags
- RebootNode
- TagResource
- UntagResource
- UpdateCluster
- UpdateParameterGroup
- UpdateSubnetGroup

DynamoDB data plane events in CloudTrail

To enable logging of the following API actions in CloudTrail files, you must enable logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type, for granular control over which DynamoDB API calls you want to selectively log and pay for in CloudTrail. For example, by specifying `AWS::DynamoDB::Stream` as a resource type, you can log only calls to the DynamoDB streams APIs. For tables with streams enabled, the resource field in the data plane event contains both `AWS::DynamoDB::Stream` and `AWS::DynamoDB::Table`. If you specify `AWS::DynamoDB::Table` as a resource type, it will log both DynamoDB table and DynamoDB streams events by default. You can add an additional filter to exclude the streams events, if you don't want the streams events to be logged. For more information, see DataResource in the *AWS CloudTrail API Reference*.

Amazon DynamoDB

- BatchExecuteStatement
- BatchGetItem
- BatchWriteItem
- DeleteItem
- ExecuteStatement
- ExecuteTransaction
- GetItem
- PutItem
- Query

- Scan
- SearchVectors
- TransactGetItems
- TransactWriteItems
- UpdateItem

> **Note**
>
> DynamoDB Time to Live data plane actions are not logged by CloudTrail

DynamoDB Streams

- GetRecords
- GetShardIterator

> **Important**
>
> When you log `GetRecords` data events, you might see `GetRecords` calls from DynamoDB internal operations, such as global tables replication. Although you are not charged by DynamoDB for these `GetRecords` calls, you are charged by CloudTrail for the data event logs. This might result in unexpected CloudTrail charges.
> To avoid unexpected CloudTrail charges, do one of the following:
>
> - Use the **Exclude AWS service-initiated events** log selector template.
> - Add an advanced event selector filter with `userIdentity.arn` set to `NotStartsWith` `AWSServiceRoleFor`.
>
> For more information, see Logging data events in the AWS CloudTrail User Guide.

Understanding DynamoDB log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single

request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

> **Note**
>
> Non key attribute values will be redacted in the CloudTrail logs of actions using the PartiQL API, and will not appear in logs of actions using the classic API.

For more information, see the CloudTrail userIdentity element.

The following examples demonstrate CloudTrail logs of these event types:

Amazon DynamoDB

- `UpdateTable`
- `DeleteTable`
- `CreateCluster`
- `PutItem` (Successful)
- `UpdateItem` (Unsuccessful)
- `TransactWriteItems` (Successful)
- `TransactWriteItems` (With `TransactionCanceledException`)
- `ExecuteStatement`
- `BatchExecuteStatement`

DynamoDB Streams

- `GetRecords`

UpdateTable

```
{
    "Records": [
        {
            "eventVersion": "1.03",
            "userIdentity": {

```

Analyzing data access using CloudWatch contributor insights for DynamoDB

Amazon CloudWatch Contributor Insights for Amazon DynamoDB is a diagnostic tool for identifying the most frequently accessed and throttled keys in your table or index at a glance. This tool uses CloudWatch contributor insights.

By enabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, you can view the most accessed and throttled items in those resources.

> **Note**
>
> CloudWatch charges apply for Contributor Insights for DynamoDB. For more information about pricing, see Amazon CloudWatch pricing.

CloudWatch contributor insights for DynamoDB: How it works

Amazon DynamoDB integrates with CloudWatch Contributor Insights to provide information about the most accessed and throttled items in a table or global secondary index. DynamoDB delivers this information to you through CloudWatch Contributor Insights rules, reports, and graphs of report data.

CloudWatch Contributor Insights for DynamoDB is designed to have no performance impact on your DynamoDB table.

For more information about CloudWatch Contributor Insights, see Using Contributor Insights to analyze high-cardinality data in the *Amazon CloudWatch User Guide*.

The following sections describe the core concepts and behavior of CloudWatch Contributor Insights for DynamoDB.

Topics

- CloudWatch contributor insights modes for DynamoDB
- CloudWatch contributor insights for DynamoDB rules
- Understanding CloudWatch contributor insights for DynamoDB graphs
- Interactions with other DynamoDB features
- CloudWatch contributor insights for DynamoDB billing

CloudWatch contributor insights modes for DynamoDB

CloudWatch Contributor Insights for DynamoDB offers two distinct modes to meet different monitoring needs.

Throttled keys mode

This mode focuses exclusively on throttled requests by only processing events when throttling occurs. It delivers insights about performance issues without the overhead of tracking all access patterns. In this mode, DynamoDB tracks only the:

- **Most throttled items** — Items that experience the most throttling events

This mode is ideal when:

- Your primary concern is identifying and resolving throttling problems
- You want to keep Contributor Insights enabled continuously for real-time throttling detection
- You want a cost-optimized approach to monitor throttling issues

> **Note**
>
> *Throttled keys mode* processes events only when throttling occurs, making it cost-effective for continuous monitoring. This targeted approach allows you to leave the feature enabled permanently with minimal cost impact, while still providing immediate visibility into throttling issues as they happen.

If your table experiences no throttling, you won't see any data in the Contributor Insights graphs, which indicates healthy performance. When throttling is detected, the generated graphs help

you identify specific access patterns causing performance issues. This information can help you implement strategies to address non-uniform access patterns.

For comprehensive monitoring strategies, you can integrate these throttling insights with other CloudWatch metrics to create unified dashboards that correlate throttling events with overall table performance.

Accessed and throttled keys mode

This mode provides comprehensive monitoring of both accessed and throttled items. In this mode, DynamoDB tracks the:

- **Most accessed items** — Items that consume the most read and write capacity
- **Most throttled items** — Items that experience the most throttling events

This mode is ideal when you need complete visibility into your table's access patterns and want to understand both high-traffic items and throttling issues.

Switching between modes

You can switch between modes at any time using the DynamoDB console, AWS CLI, or APIs. When you switch modes:

- Existing CloudWatch rules are updated to match the new mode
- Throttled keys CloudWatch rules remain intact, maintaining your continuous historical data for throttling metrics:
  - When you switch from *throttled keys* mode to *accessed and throttled keys* mode, the existing throttled key rules are preserved, and new accessed key rules are created
  - When you switch from *accessed and throttled keys* mode to *throttled keys* mode, only the throttled key rules are preserved, and the accessed key rules are removed
- Billing adjusts immediately to reflect the new mode's event processing

CloudWatch contributor insights for DynamoDB rules

When you enable CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, DynamoDB creates rules on your behalf based on the selected mode.

> **Note**
>
> When you enable Contributor Insights on your DynamoDB table, you're subject to Contributor Insights rules limits. For more information, see CloudWatch service quotas.

Rules for accessed and throttled keys mode

In *accessed and throttled keys* mode, DynamoDB creates the following rules:

- **Most accessed items (partition keys)** — Identifies the partition keys of the most accessed items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-PKC-[resource_name]-[creationtimestamp]`
- **Most throttled keys (partition keys)** — Identifies the partition keys of the most throttled items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-PKT-[resource_name]-[creationtimestamp]`

If your table or global secondary index has sort keys, DynamoDB also creates the following rules specific to sort keys:

- **Most accessed keys (partition and sort keys)** — Identifies the partition and sort keys of the most accessed items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-SKC-[resource_name]-[creationtimestamp]`
- **Most throttled keys (partition and sort keys)** — Identifies the partition and sort keys of the most throttled items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-SKT-[resource_name]-[creationtimestamp]`

Rules for throttled keys mode

In *throttled keys* mode, DynamoDB creates only the throttling-related rules:

- **Most throttled keys (partition key)** — Identifies the partition keys of the most throttled items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-PKT-[resource_name]-[creationtimestamp]`

If your table or global secondary index has sort keys, DynamoDB also creates:

- **Most throttled keys (partition and sort keys)** — Identifies the partition and sort keys of the most throttled items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-SKT-[resource_name]-[creationtimestamp]`

This focused approach reduces the number of active rules and decreases the volume of events processed to better diagnose your throttling events.

Note

- When you use the CloudWatch console or APIs to view CloudWatch Contributor Insights for DynamoDB, you only see rules corresponding to your selected mode.
- You can't use the CloudWatch console or APIs to directly modify or delete the rules created by CloudWatch Contributor Insights for DynamoDB. Disabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index automatically deletes the rules created for that table or global secondary index.
- When you use the GetInsightRuleReport operation with CloudWatch Contributor Insights rules that are created by DynamoDB, only `MaxContributorValue` and `Maximum` return useful statistics. The other statistics in this list don't return meaningful values.
- CloudWatch Contributor Insights for DynamoDB has a limit of 25 contributors. Requesting more than 25 contributors will return an error.

You can create CloudWatch Alarms using the CloudWatch Contributor Insights for DynamoDB rules. This allows you to be notified when any item exceed or meets a specific threshold for `ConsumedThroughputUnits` or `ThrottleCount`. For more information, see Setting an alarm on Contributor Insights metric data.

Understanding CloudWatch contributor insights for DynamoDB graphs

CloudWatch Contributor Insights for DynamoDB displays different types of graphs on both the DynamoDB and CloudWatch consoles depending on the selected mode.

Graph availability by mode

The graphs displayed depend on your selected Contributor Insights mode.

- **Accessed and throttled keys mode** displays both *Most Accessed Items* and *Most Throttled Items* graphs
- **Throttled keys mode** displays only *Most Throttled Items* graphs

Most accessed items

This graph is available only in accessed and throttled keys mode. Use this graph to identify the most accessed items in the table or global secondary index. The graph displays `ConsumedThroughputUnits` on the y-axis and time on the x-axis. Each of the top N keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures key access frequency by using `ConsumedThroughputUnits`, which measures combined read and write traffic. `ConsumedThroughputUnits` is defined as the following:

- Provisioned — *(3 x consumed write capacity units) + consumed read capacity units*
- On-demand — *(3 x write request units) + read request units*

On the DynamoDB console, each data point in the graph represents the maximum of `ConsumedThroughputUnits` over a 1-minute period. For example, a graph value of 180,000 `ConsumedThroughputUnits` indicates that the item was accessed continuously at the per-item maximum throughput of 1,000 write request units or 3,000 read request units for a 60-second span within that 1-minute period (3,000 x 60 seconds). In other words, the graphed values represent the highest-traffic minute within each 1-minute period. You can change the time granularity of the `ConsumedThroughputUnits` metric (for example, to view 5-minute metrics instead of 1-minute) on the CloudWatch console.

If you see several closely clustered lines without any obvious outliers, it indicates that your workload is relatively balanced across items over the given time window. If you see isolated points

in the graph instead of connected lines, it indicates an item that was frequently accessed only for a brief period.

If your table or global secondary index has sort keys, DynamoDB creates two graphs: one for the most accessed partition keys and one for the most accessed partition + sort keys pairs. You can see traffic at the partition keys level in the partition key–only graph. You can see traffic at the item level in the partition + sort keys graphs.

Most throttled items

This graph is available in both modes. Use this graph to identify the most throttled items in the table or global secondary index. The graph displays `ThrottleCount` on the y-axis and time on the x-axis. Each of the top *N* keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures throttle frequency using `ThrottleCount`, which is the count of `ProvisionedThroughputExceededException`, `ThrottlingException`, and `RequestLimitExceeded` errors.

Write throttling caused by insufficient write capacity for a global secondary index is not measured. You can use the *Most Accessed Items* graph of the global secondary index to identify imbalanced access patterns that may cause write throttling. For more information, see Provisioned throughput Considerations for Global Secondary Indexes.

On the DynamoDB console, each data point in the graph represents the count of throttle events over a 1-minute period.

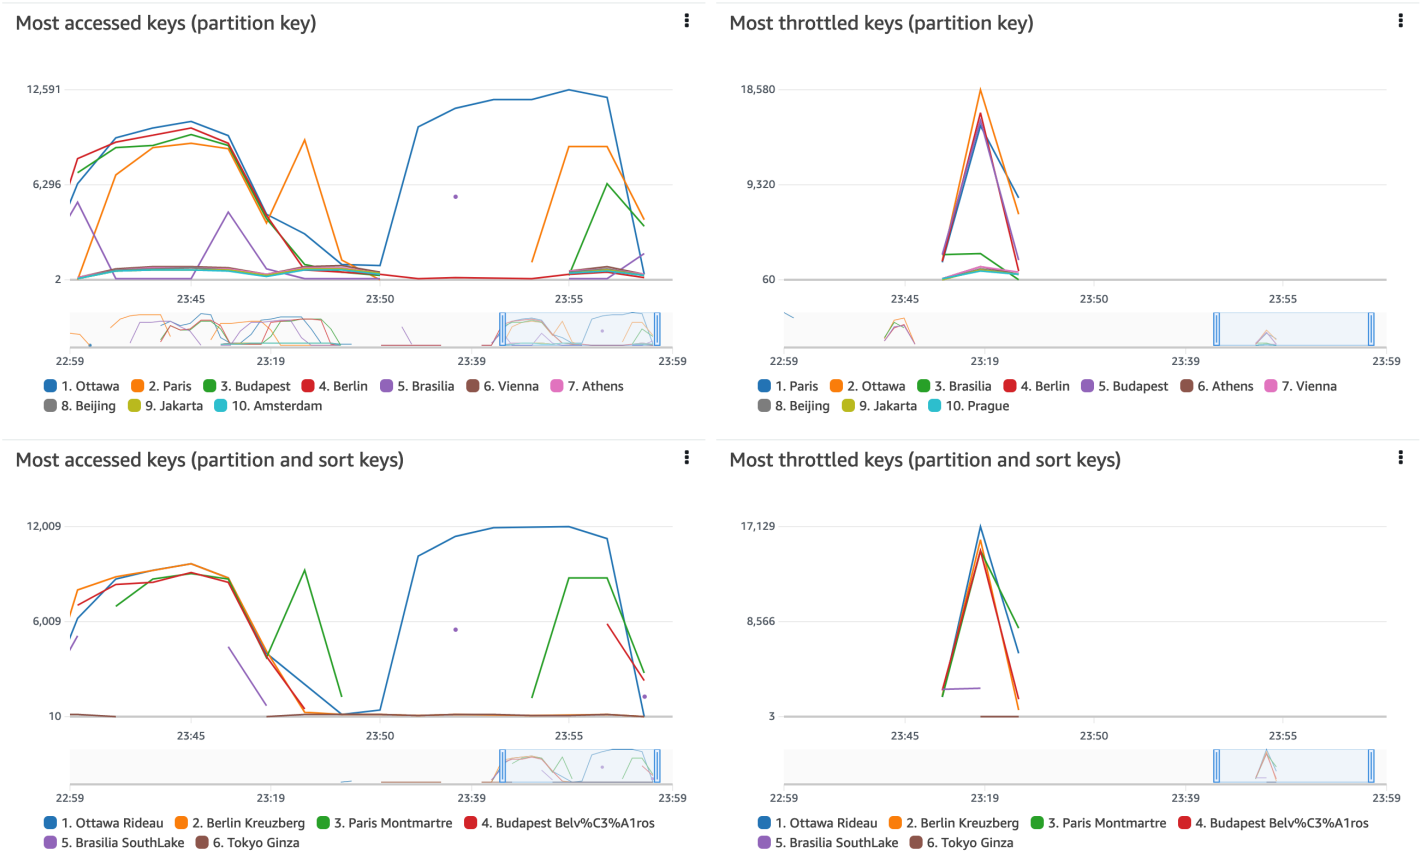
If you see no data in this graph, it indicates that your requests are not being throttled. If you see isolated points in the graph instead of connected lines, it indicates that an item was frequently throttled for a brief period.

If your table or global secondary index has sort keys, DynamoDB creates two graphs: one for most throttled partition keys and one for most throttled partition + sort keys pairs. You can see throttle count at the partition keys level in the partition keys-only graph, and throttle count at the item-level in the partition + sort keys graphs.

> **Note**
>
> In *throttled keys* mode, this is the only type of graph you'll see. The absence of data in these graphs indicates healthy table performance with no throttling occurring.

Report examples

The following example shows the reports generated for a table with both a partition keys and sort keys in *accessed and throttled keys* modes. In *throttled keys* mode, you see only the throttling-related portion of this report.



Interactions with other DynamoDB features

The following sections describe how CloudWatch Contributor Insights for DynamoDB behaves and interacts with several other features in DynamoDB. These behaviors apply to both modes unless otherwise specified.

Global tables

CloudWatch Contributor Insights for DynamoDB monitors global table replicas as distinct tables. The Contributor Insights graphs for a replica in one AWS Region might not show the same patterns as another Region. This is because write data is replicated across all replicas in a global table, but each replica can serve Region-bound read traffic.

Each replica can be configured with a different Contributor Insights mode independently. For example, you might use *accessed and throttled keys* mode in your primary region for comprehensive monitoring, while using *throttled keys* mode in secondary regions to maintain visibility into performance issues.

DynamoDB Accelerator (DAX)

CloudWatch Contributor Insights for DynamoDB doesn't show DAX cache responses. It only shows responses to accessing a table or a global secondary index.

> **Note**
>
> DynamoDB CloudWatch Contributor Insights does not support PartiQL requests.

Encryption at rest

CloudWatch Contributor Insights for DynamoDB doesn't affect how encryption works in DynamoDB. The primary key data that is published in CloudWatch is encrypted with the AWS owned key. However, DynamoDB also supports the AWS managed key and a customer managed key.

CloudWatch Contributor Insights for DynamoDB displays partition keys and sort keys (if applicable) of frequently accessed and throttled items. While CloudWatch Contributor Insights works with encrypted DynamoDB tables, it's important to note that it uses its own Amazon-owned encryption context, which is separate from the table's configured encryption.

If your DynamoDB table's primary key contains sensitive information and your organization's security policies require full control over encryption processes, enabling CloudWatch Contributor Insights may not be suitable.

Fine-grained access control

CloudWatch Contributor Insights for DynamoDB doesn't function differently for tables with fine-grained access control (FGAC). In other words, any user who has the appropriate CloudWatch permissions can view FGAC-protected primary keys in CloudWatch Contributor Insights graphs.

If the table's primary key contains FGAC-protected data that you don't want published to CloudWatch, you should not enable CloudWatch Contributor Insights for DynamoDB for that table.

Access control

You control access to CloudWatch Contributor Insights for DynamoDB using AWS Identity and Access Management (IAM) by limiting DynamoDB control plane permissions and CloudWatch data plane permissions. For more information see, Using IAM with CloudWatch Contributor Insights for DynamoDB.

CloudWatch contributor insights for DynamoDB billing

Charges for CloudWatch Contributor Insights for DynamoDB appear in the CloudWatch section of your monthly bill. These charges have two components: a fixed monthly charge for each Contributor Insights rule that is created when you turn on the feature, and a charge based on the number of DynamoDB events that are processed, which varies with the selected mode.

Billing by mode

The two Contributor Insights modes have different billing characteristics.

- **Accessed and throttled keys mode billing** - In this mode, each item that is written or read via a data plane operation represents one event, regardless of whether the request succeeds or is throttled. If a table or global secondary index includes sort keys, each item that is read or written represents two events. This is because DynamoDB is identifying top contributors from separate time series: one for partitions keys only, and one for partition and sort keys pairs.
- **Throttled keys mode billing** - In this mode, only throttled requests generate billable events. Events are only generated when requests result in `ProvisionedThroughputExceededException`, `ThrottlingException`, or `RequestLimitExceeded` errors. If a table or global secondary index includes sort keys, each throttled item represents two events (partition keys tracking and partition + sort keys tracking).

Billing examples

For example, assume that your application performs the following DynamoDB operations: a `GetItem`, a `PutItem`, and a `BatchWriteItem` that puts five items. Also assume that the `PutItem` operation gets throttled, but all other operations succeed.

- **Accessed and throttled keys mode**
  - If your table or global secondary index has only a partition keys, it results in 7 events (1 for the `GetItem`, 1 for the `PutItem`, and 5 for the `BatchWriteItem`).

- If your table or global secondary index has a partition keys and sort keys, it results in 14 events (2 for the `GetItem`, 2 for the `PutItem`, and 10 for the `BatchWriteItem`).

- **Throttled keys mode**
  - If your table or global secondary index has only a partition keys, it results in 1 event (only for the throttled `PutItem`).
  - If your table or global secondary index has a partition keys and sort keys, it results in 2 events (2 for the throttled `PutItem`).

  The successful `GetItem` and `BatchWriteItem` operations generate no events in throttled keys mode.

Common billing factors

A`Query` operation always results in 1 event, regardless of the mode or number of items returned.

Unlike other DynamoDB features, CloudWatch Contributor Insights for DynamoDB billing *does not* vary based on the following:

- The capacity mode (provisioned vs. on-demand)
- Whether you perform read or write requests
- The size (KB) of the items read or written

Getting started with CloudWatch Contributor Insights for DynamoDB

This section describes how to enable and use Amazon CloudWatch Contributor Insights in different modes to meet your monitoring needs using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

In the following examples, you use the DynamoDB table that is defined in the Getting started with DynamoDB tutorial.

Topics

- Choosing a Contributor Insights mode
- Using Contributor Insights (console)
- Using Contributor Insights (AWS CLI)

Choosing a Contributor Insights mode

Before enabling Contributor Insights, you should understand the two available modes. Review the mode comparison to select the option that best aligns with your specific requirements.

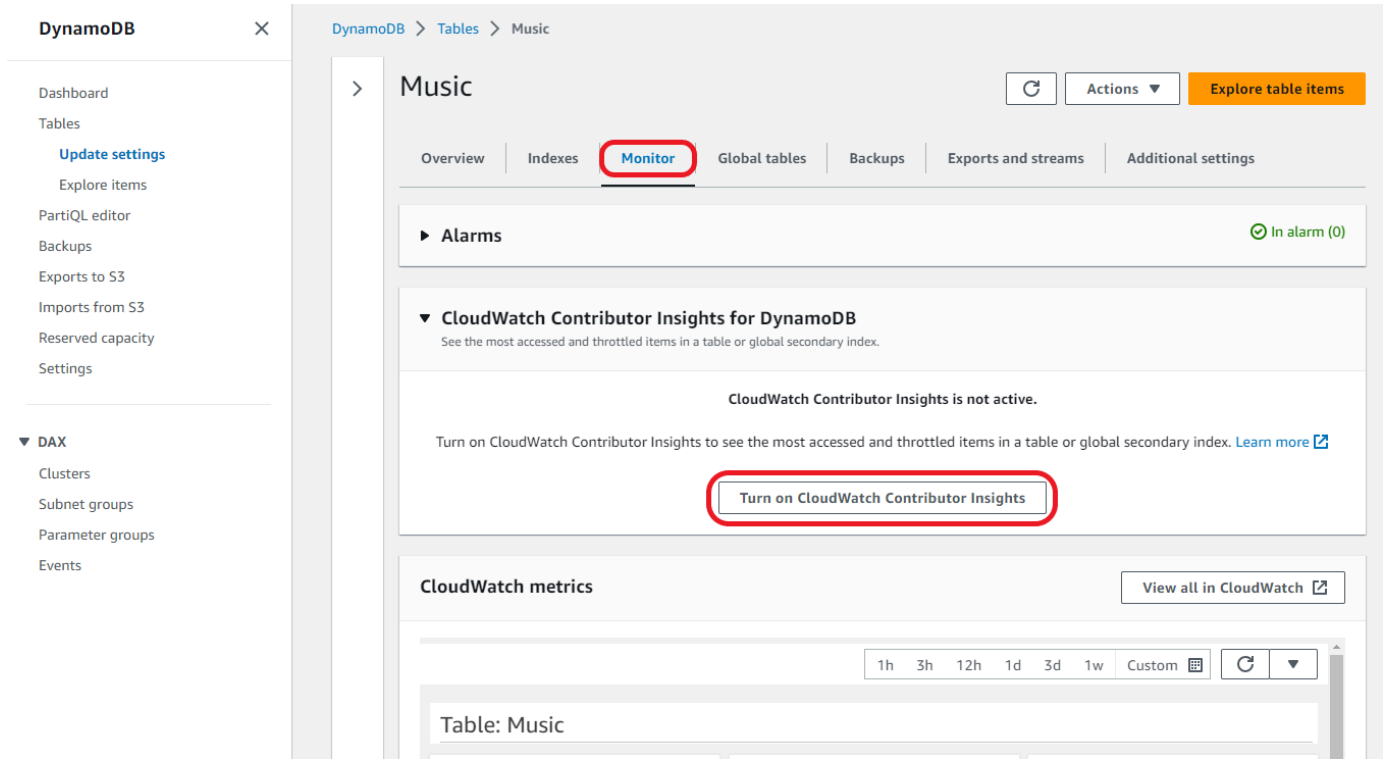
Aspect	Accessed and throttled keys mode	Throttled keys mode
Monitors	All requests (successful and throttled)	Only throttled requests
Graphs	Most Accessed Items + Most Throttled Items	Most Throttled Items only
Best for	Targeted analysis and optimization	Throttling monitoring
Use when	You need complete visibility into access patterns. You're doing short-term analysis or debugging.	Your primary concern is identifying and resolving throttling issues. You want to keep Contributor Insights enabled continuously for real-time throttling alerts.

Using Contributor Insights (console)

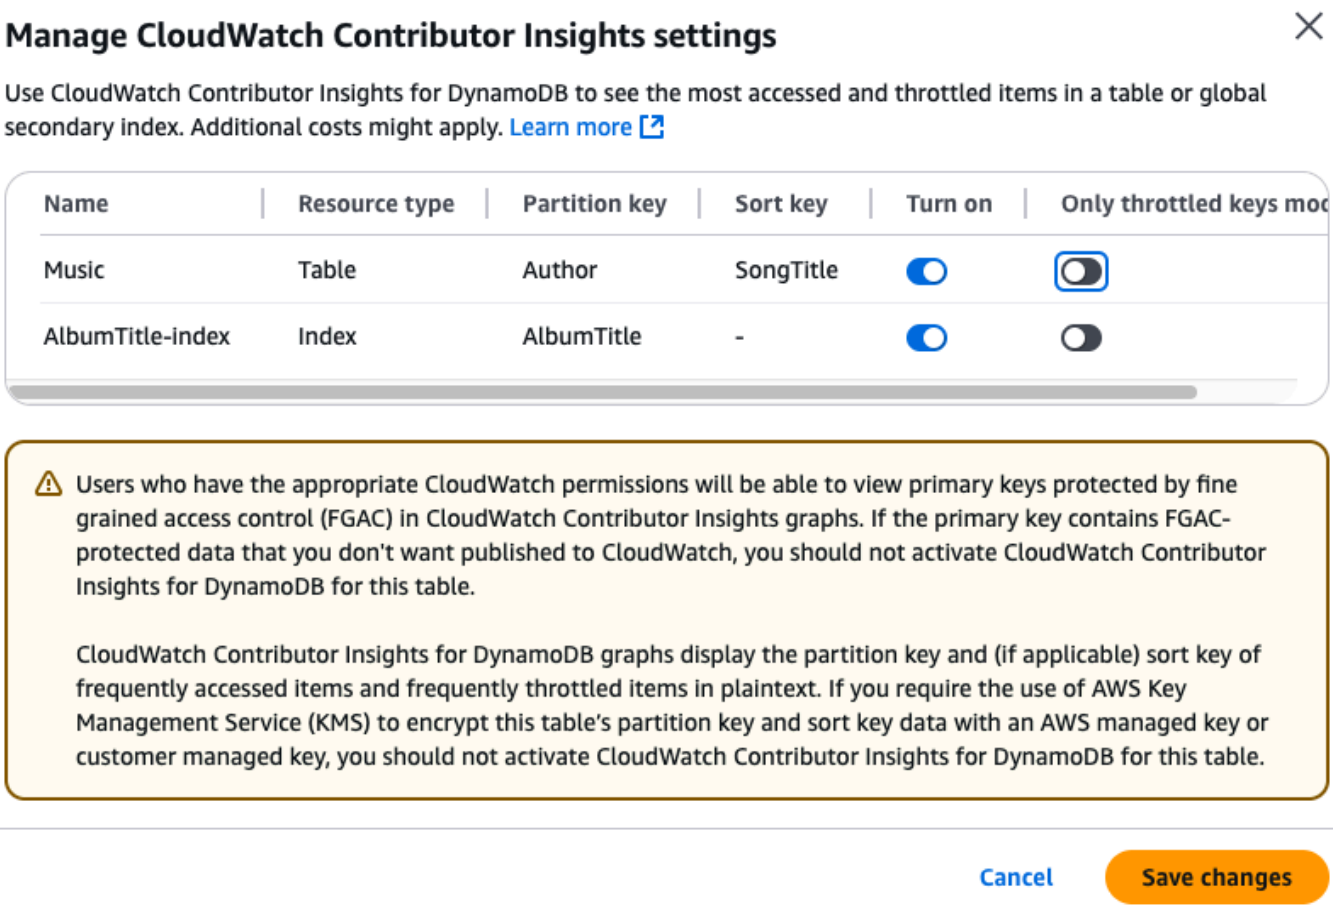
The console provides an intuitive way to enable Contributor Insights and select the appropriate mode for your monitoring needs.

To use Contributor Insights in the console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the `Music` table.
4. Choose the **Monitor** tab.
5. Choose **Turn on CloudWatch Contributor Insights**.



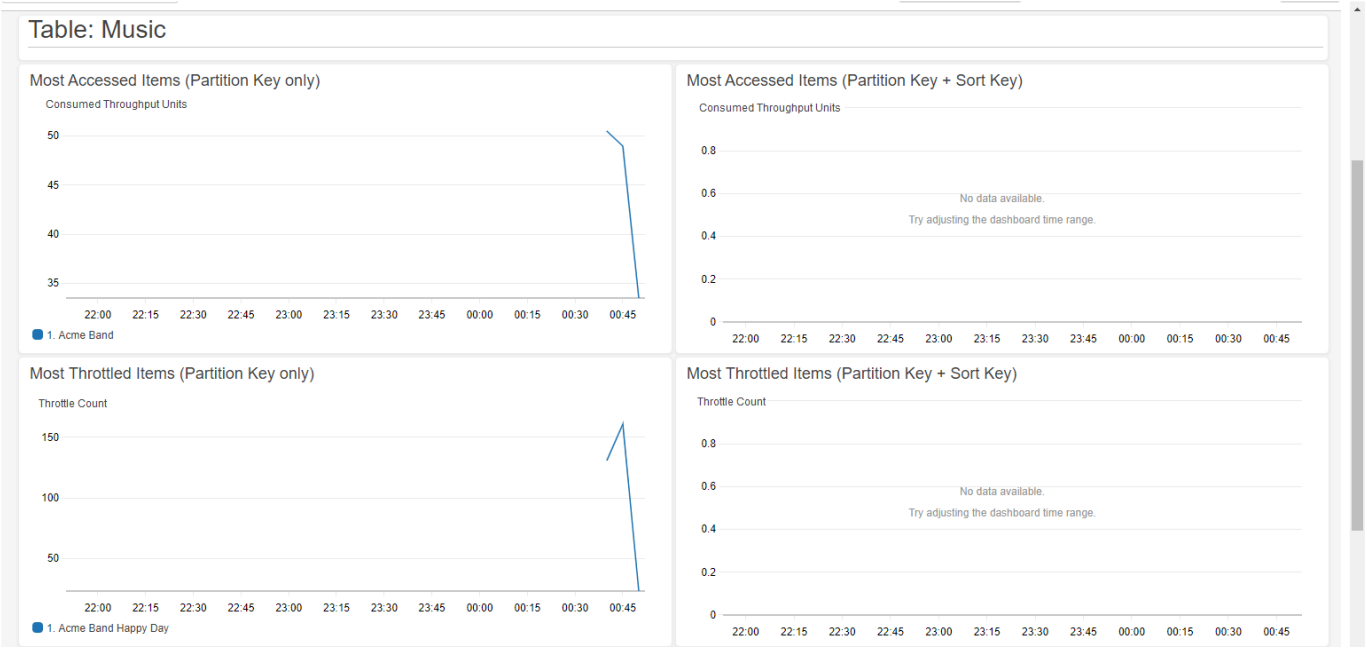
6. In the **Manage CloudWatch Contributor Insights settings** dialog box, toggle **Turn on** for both the `Music` base table and the `AlbumTitle-index` global secondary index.
7. Leave the **Only throttled keys mode** toggle in the off position for both and then choose **Save changes**.



This enables the default *accessed and throttled keys* mode for both the table and GSI, which provides monitoring of both accessed and throttled items. Switching the **Only throttled keys mode** toggle to the on position would enable the *throttled keys* mode.

If the operation fails, see DescribeContributorInsights FailureException in the *Amazon DynamoDB API Reference* for possible reasons.

8. The CloudWatch Contributor Insights graphs are now visible on the **Monitor** tab for the `Music` table. Since you enabled *accessed and throttled keys* mode, you see both accessed and throttled item graphs.



Switching between modes

You can switch between modes at any time without disabling Contributor Insights.

To switch Contributor Insights modes

1. On the **Monitor** tab of your table, choose **Manage CloudWatch Contributor Insights**.
2. In the **Manage Contributor Insights settings** dialog box, for each base table or GSIs:
   - Toggle **Only throttled keys mode** on or off to enable the *throttled keys* mode or go back to the default *accessed and throttled keys* mode.
   - Toggle **Turn on** off to disable CloudWatch Contributor Insight for a table or GSI.
3. Choose **Save changes**.

   After this is complete, the graphs will reflect the new mode.

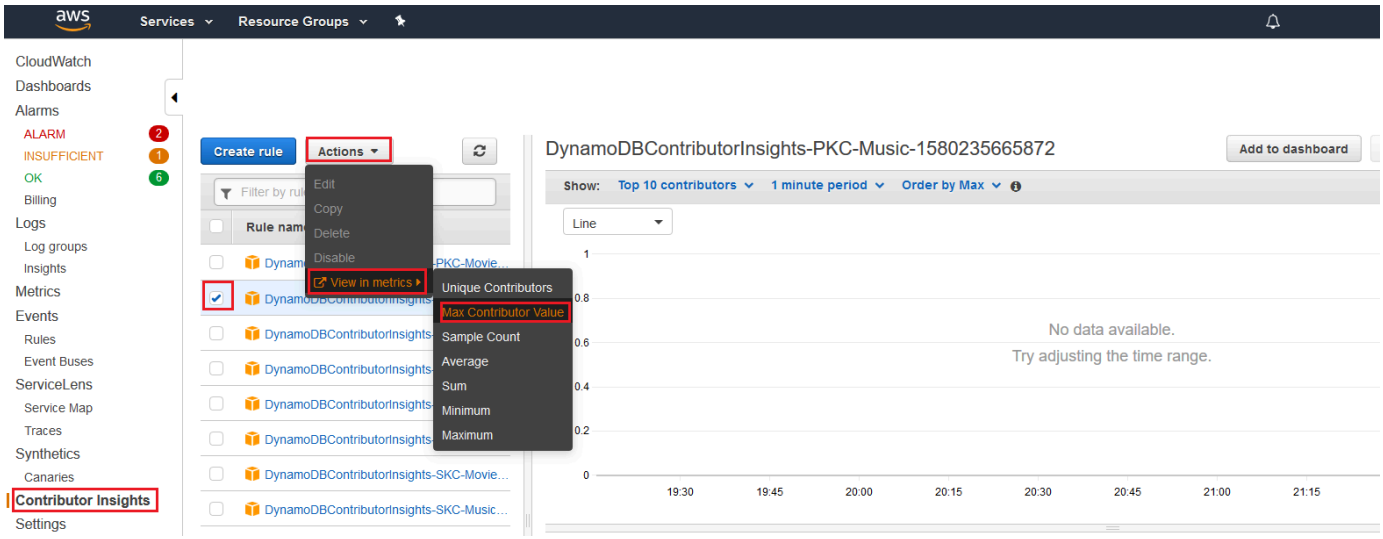
Creating CloudWatch alarms

Follow these steps to create a CloudWatch alarm and be notified when any partition key consumes more than 50,000 ConsumedThroughputUnits or experiences throttling.

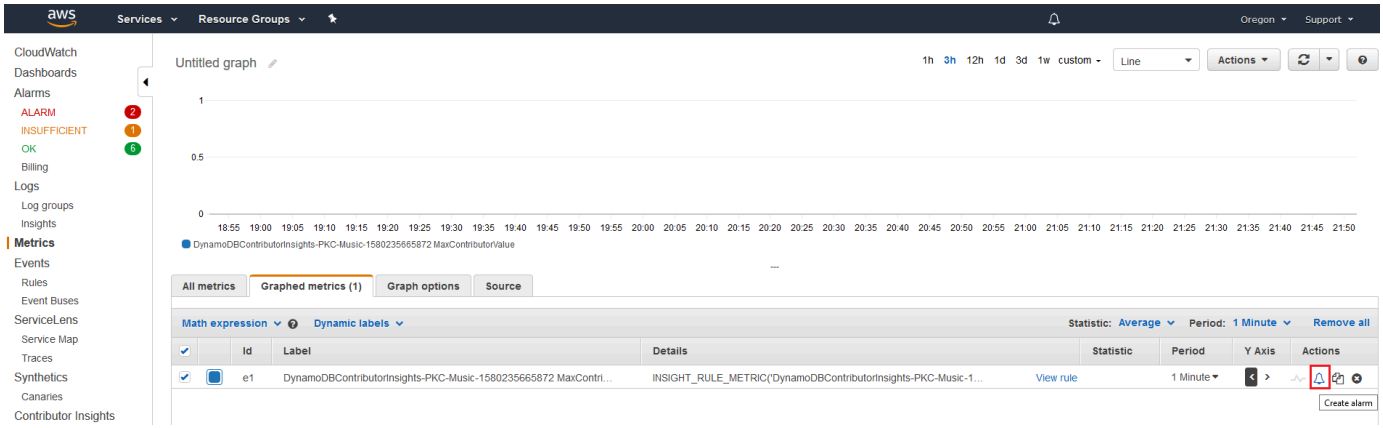
1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/

2. In the navigation pane on the left side of the console, choose **Contributor Insights**.
3. Choose the appropriate rule based on your mode and what you want to monitor:
   - For accessed items monitoring (accessed and throttled keys mode only): Choose **DynamoDBContributorInsights-PKC-Music**
   - For throttled items monitoring (both modes): Choose **DynamoDBContributorInsights-PKT-Music**
4. Choose the **Actions** drop down.
5. Choose **View in metrics**.
6. Choose **Max Contributor Value**.

> **Note**
>
> Only `Max Contributor Value` and `Maximum` return useful statistics. The other statistics in this list don't return meaningful values.

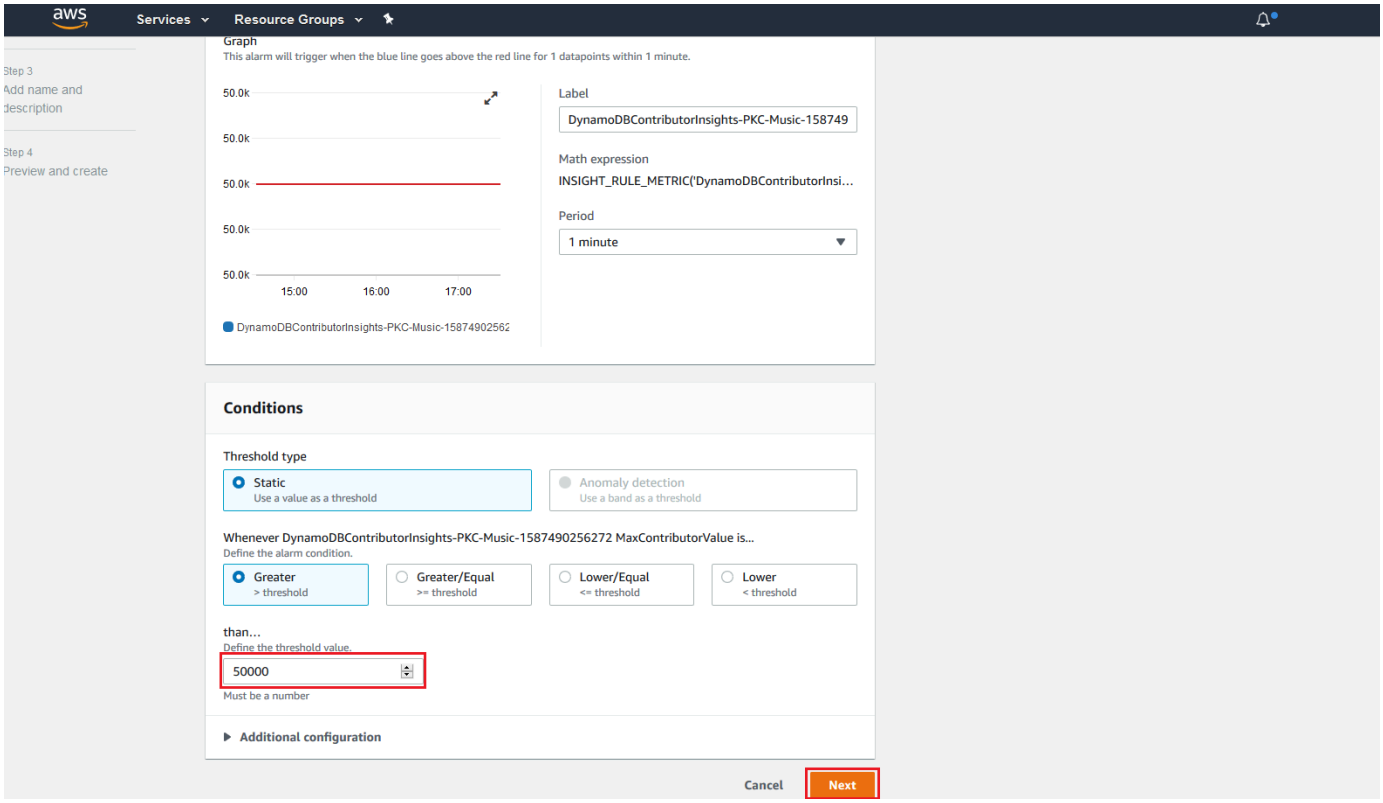


7. On the **Actions** column, Choose **Create Alarm**.



8. Enter an appropriate threshold value and choose **Next**:

   - For accessed items (PKC rules): Enter 50000 for `ConsumedThroughputUnits`
   - For throttled items (PKT rules): Enter 1 for `ThrottleCount` to be alerted on any throttling



9. See Using Amazon CloudWatch alarms for details on how to configure the notification for the alarm.

Using Contributor Insights (AWS CLI)

The AWS CLI provides programmatic access to Contributor Insights with full support for both modes. You can specify the mode when enabling Contributor Insights or switch modes later.

Basic operations with default mode

To use Contributor Insights with default settings

1. Enable CloudWatch Contributor Insights for DynamoDB on the `Music` base table with the *accessed and throttled keys* mode. Since `ACCESSED_AND_THROTTLED_KEYS` is the default mode, you can omit the `--contributor-insights-mode=ACCESSED_AND_THROTTLED_KEYS` parameter.

   ```
   aws dynamodb update-contributor-insights \
                       --table-name Music \
                       --contributor-insights-action=ENABLE
   ```

2. Enable Contributor Insights for DynamoDB on the `AlbumTitle-index` global secondary index.

   ```
   aws dynamodb update-contributor-insights \
                       --table-name Music \
                       --index-name AlbumTitle-index \
                       --contributor-insights-action=ENABLE
   ```

3. Get the status and rules for the `Music` table and all its indexes.

   ```
   aws dynamodb describe-contributor-insights
                       --table-name Music
   ```

   The response will include the `ContributorInsightsMode` field showing `ACCESSED_AND_THROTTLED_KEYS`.

4. List the status of the `Music` table and all its indexes.

   ```
   aws dynamodb list-contributor-insights --table-name Music
   ```

Enabling throttled keys mode

To enable Contributor Insights in throttled keys mode

1. Enable CloudWatch Contributor Insights for DynamoDB on the `Music` base table with *throttled keys* mode.

```
aws dynamodb update-contributor-insights \
    --table-name Music \
    --contributor-insights-action=ENABLE \
    --contributor-insights-mode=THROTTLED_KEYS
```

2. Enable Contributor Insights in *throttled keys* mode for the `AlbumTitle-index` global secondary index.

```
aws dynamodb update-contributor-insights \
    --table-name Music \
    --index-name AlbumTitle-index \
    --contributor-insights-action=ENABLE \
    --contributor-insights-mode=THROTTLED_KEYS
```

3. Verify the mode by describing the Contributor Insights configuration.

```
aws dynamodb describe-contributor-insights --table-name Music
```

   The response will show `ContributorInsightsMode` as `THROTTLED_KEYS` and fewer rules compared to the default mode.

Switching between modes

To switch Contributor Insights modes

1. Switch from *throttled keys* mode to *accessed and throttled keys* mode.

```
aws dynamodb update-contributor-insights \
    --table-name Music \
    --contributor-insights-action=ENABLE \
    --contributor-insights-mode=ACCESSED_AND_THROTTLED_KEYS
```

2. Switch from *accessed and throttled keys* mode to *throttled keys* mode.

```
aws dynamodb update-contributor-insights \
    --table-name Music \
    --contributor-insights-action=ENABLE \
    --contributor-insights-mode=THROTTLED_KEYS
```

3. Check the status during the transition.

```
aws dynamodb describe-contributor-insights --table-name Music
```

During the mode switch, the `ContributorInsightsStatus` will show as `ENABLING`. After this is complete, it will show as `ENABLED` with the new mode.

Managing Contributor Insights

To manage Contributor Insights settings

1. Disable CloudWatch Contributor Insights for DynamoDB on the `AlbumTitle-index` global secondary index.

```
aws dynamodb update-contributor-insights \
                    --table-name Music --index-name AlbumTitle-index \
                    --contributor-insights-action=DISABLE
```

2. List all Contributor Insights configurations in your account.

```
aws dynamodb list-contributor-insights
```

This shows all tables and indexes with Contributor Insights enabled, along with their modes.

3. Get detailed information about a specific configuration.

```
aws dynamodb describe-contributor-insights \
                    --table-name Music \
                    --index-name AlbumTitle-index
```

Example responses

Here are example responses showing the differences between modes:

Accessed and throttled keys mode response

```
{
    "TableName": "Music",
    "ContributorInsightsRuleList": [
        "DynamoDBContributorInsights-PKC-Music-1234567890123",
        "DynamoDBContributorInsights-PKT-Music-1234567890123",
        "DynamoDBContributorInsights-SKC-Music-1234567890123",
        "DynamoDBContributorInsights-SKT-Music-1234567890123"
    ],
    "ContributorInsightsStatus": "ENABLED",
    "ContributorInsightsMode": "ACCESSED_AND_THROTTLED_KEYS",
    "LastUpdateDateTime": "2024-01-15T10:30:00.000Z"
}
```

Throttled keys mode response

```
{
    "TableName": "Music",
    "ContributorInsightsRuleList": [
        "DynamoDBContributorInsights-PKT-Music-1234567890123",
        "DynamoDBContributorInsights-SKT-Music-1234567890123"
    ],
    "ContributorInsightsStatus": "ENABLED",
    "ContributorInsightsMode": "THROTTLED_KEYS",
    "LastUpdateDateTime": "2024-01-15T10:35:00.000Z"
}
```

Notice that throttled keys mode has fewer rules (only PKT and SKT), which corresponds to a more focused monitoring.

Using IAM with CloudWatch contributor insights for DynamoDB

The first time that you enable Amazon CloudWatch Contributor Insights for Amazon DynamoDB, DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role, `AWSServiceRoleForDynamoDBCloudWatchContributorInsights`, allows DynamoDB to manage CloudWatch Contributor Insights rules on your behalf. Don't delete this service-linked role. If you delete it, all your managed rules will no longer be cleaned up when you delete your table or global secondary index.

For more information about service-linked roles, see Using service-linked roles in the *IAM User Guide*.

The following permissions are required:

- To enable or disable CloudWatch Contributor Insights for DynamoDB, you must have `dynamodb:UpdateContributorInsights` permission on the table or index.
- To view CloudWatch Contributor Insights for DynamoDB graphs, you must have `cloudwatch:GetInsightRuleReport` permission.
- To describe CloudWatch Contributor Insights for DynamoDB for a given DynamoDB table or index, you must have `dynamodb:DescribeContributorInsights` permission.
- To list CloudWatch Contributor Insights for DynamoDB statuses for each table and global secondary index, you must have `dynamodb:ListContributorInsights` permission.

Example: Enable or disable CloudWatch contributor insights for DynamoDB

The following IAM policy grants permissions to enable or disable CloudWatch Contributor Insights for DynamoDB.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "arn:aws:iam::*:role/aws-
service-role/contributorinsights.dynamodb.amazonaws.com/
AWSServiceRoleForDynamoDBCloudWatchContributorInsights",
            "Condition": {"StringLike": {"iam:AWSServiceName":
 "contributorinsights.dynamodb.amazonaws.com"}}
        },
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:UpdateContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*"
```

```
        }
    ]
}
```

For tables encryped by KMS key, the user needs to have kms:Decrypt permissions in order to update Contributor Insights.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "arn:aws:iam::*:role/aws-
service-role/contributorinsights.dynamodb.amazonaws.com/
AWSServiceRoleForDynamoDBCloudWatchContributorInsights",
            "Condition": {
                "StringLike": {
                    "iam:AWSServiceName":
 "contributorinsights.dynamodb.amazonaws.com"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:UpdateContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*"
        },
        {
            "Effect": "Allow",
            "Resource": "arn:aws:kms:*:*:key/*",
            "Action": [
                "kms:Decrypt"
            ]
        }
    ]
}
```

Example: Retrieve CloudWatch contributor insights rule report

The following IAM policy grants permissions to retrieve CloudWatch Contributor Insights rule report.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetInsightRuleReport"
            ],
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/
DynamoDBContributorInsights*"
        }
    ]
}
```

Example: Selectively apply CloudWatch contributor insights for DynamoDB permissions based on resource

The following IAM policy grants permissions to allow the `ListContributorInsights` and `DescribeContributorInsights` actions and denies the `UpdateContributorInsights` action for a specific global secondary index.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:ListContributorInsights",
                "dynamodb:DescribeContributorInsights"
            ],
```

```
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:UpdateContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books/
index/Author-index"
        }
    ]
}
```

Using service-linked roles for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Contributor Insights for DynamoDB. Service-linked roles are predefined by CloudWatch Contributor Insights for DynamoDB and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up CloudWatch Contributor Insights for DynamoDB easier because you don't have to manually add the necessary permissions. CloudWatch Contributor Insights for DynamoDB defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Contributor Insights for DynamoDB can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses the service-linked role named **AWSServiceRoleForDynamoDBCloudWatchContributorInsights**. The purpose of the service-linked role is to allow Amazon DynamoDB to manage Amazon CloudWatch Contributor Insights rules created for DynamoDB tables and global secondary indexes, on your behalf.

The `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role trusts the following services to assume the role:

- `contributorinsights.dynamodb.amazonaws.com`

The role permissions policy allows CloudWatch Contributor Insights for DynamoDB to complete the following actions on the specified resources:

- Action: `Create and manage Insight Rules` on `DynamoDBContributorInsights`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the *IAM User Guide*.

Creating a service-linked role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually create a service-linked role. When you enable Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable Contributor Insights, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you again.

Editing a service-linked role for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB does not allow you to edit the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually delete the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` role. When you disable Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB cleans up the resources.

You can also use the IAM console, the AWS CLI or the AWS API to manually delete the service-linked role. To do this, you must first manually clean up the resources for your service-linked role and then you can manually delete it.

> **Note**
>
> If the CloudWatch Contributor Insights for DynamoDB service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

NoSQL design for DynamoDB

NoSQL database systems like Amazon DynamoDB use alternative models for data management, such as key-value pairs or document storage. When you switch from a relational database management system to a NoSQL database system like DynamoDB, it's important to understand the key differences and specific design approaches.

Topics

- Differences between relational data design and NoSQL
- Two key concepts for NoSQL design
- Approaching NoSQL design
- NoSQL Workbench for DynamoDB

Differences between relational data design and NoSQL

Relational database systems (RDBMS) and NoSQL databases have different strengths and weaknesses:

- In RDBMS, data can be queried flexibly, but queries are relatively expensive and don't scale well in high-traffic situations (see First steps for modeling relational data in DynamoDB).
- In a NoSQL database such as DynamoDB, data can be queried efficiently in a limited number of ways, outside of which queries can be expensive and slow.

These differences make database design different between the two systems:

- In RDBMS, you design for flexibility without worrying about implementation details or performance. Query optimization generally doesn't affect schema design, but normalization is important.
- In DynamoDB, you design your schema specifically to make the most common and important queries as fast and as inexpensive as possible. Your data structures are tailored to the specific requirements of your business use cases.

Two key concepts for NoSQL design

NoSQL design requires a different mindset than RDBMS design. For an RDBMS, you can go ahead and create a normalized data model without thinking about access patterns. You can then extend it

later when new questions and query requirements arise. You can organize each type of data into its own table.

How NoSQL design is different

- By contrast, you shouldn't start designing your schema for DynamoDB until you know the questions it will need to answer. Understanding the business problems and the application use cases up front is essential.
- You should maintain as few tables as possible in a DynamoDB application. Having fewer tables keeps things more scalable, requires less permissions management, and reduces overhead for your DynamoDB application. It can also help keep backup costs lower overall.

Approaching NoSQL design

The first step in designing your DynamoDB application is to identify the specific query patterns that the system must satisfy.

In particular, it is important to understand three fundamental properties of your application's access patterns before you begin:

- **Data size**: Knowing how much data will be stored and requested at one time will help determine the most effective way to partition the data.
- **Data shape**: Instead of reshaping data when a query is processed (as an RDBMS system does), a NoSQL database organizes data so that its shape in the database corresponds with what will be queried. This is a key factor in increasing speed and scalability.
- **Data velocity**: DynamoDB scales by increasing the number of physical partitions that are available to process queries, and by efficiently distributing data across those partitions. Knowing in advance what the peak query loads will be might help determine how to partition data to best use I/O capacity.

After you identify specific query requirements, you can organize data according to general principles that govern performance:

- **Keep related data together.** Research has shown that the principle of 'locality of reference', keeping related data together in one place, is a key factor in improving performance and response times in NoSQL systems, just as it was found to be important for optimizing routing tables many years ago.

As a general rule, you should maintain as few tables as possible in a DynamoDB application.

Exceptions are cases where high-volume time series data are involved, or datasets that have very different access patterns. A single table with inverted indexes can usually enable simple queries to create and retrieve the complex hierarchical data structures required by your application.

- **Use sort order.** Related items can be grouped together and queried efficiently if their key design causes them to sort together. This is an important NoSQL design strategy.
- **Distribute queries.** It's also important that a high volume of queries not be focused on one part of the database, where they can exceed I/O capacity. Instead, you should design data keys to distribute traffic evenly across partitions as much as possible, avoiding hot spots.
- **Use global secondary indexes.** By creating specific global secondary indexes, you can enable different queries than your main table can support, and that are still fast and relatively inexpensive.

These general principles translate into some common design patterns that you can use to model data efficiently in DynamoDB.

NoSQL Workbench for DynamoDB

NoSQL Workbench for DynamoDB is a cross-platform, client-side GUI application that you can use for modern database development and operations. It's available for Windows, macOS, and Linux. NoSQL Workbench is a visual development tool that provides data modeling, data visualization, sample data generation, and query development features to help you design, create, query, and manage DynamoDB tables. With NoSQL Workbench for DynamoDB, you can build new data models from, or design models based on, existing data models that satisfy your application's data access patterns. You can also import and export the designed data model at the end of the process. For more information, see Building data models with NoSQL Workbench.

Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload

This section describes the Amazon DynamoDB Well-Architected Lens, a collection of design principles and guidance for designing well-architected DynamoDB workloads.

Optimizing costs on DynamoDB tables

This section covers best practices on how to optimize costs for your existing DynamoDB tables. You should look at the following strategies to see which cost optimization strategy best suits your needs and approach them iteratively. Each strategy will provide an overview of what might be impacting your costs, what signs to look for, and prescriptive guidance on how to reduce them.

Topics

- Evaluate your costs at the table level
- Evaluate your DynamoDB table's capacity mode
- Evaluate your DynamoDB table's auto scaling settings
- Evaluate your DynamoDB table class selection
- Identify your unused resources in DynamoDB
- Evaluate your DynamoDB table usage patterns
- Evaluate your DynamoDB streams usage
- Evaluate your provisioned capacity for right-sized provisioning in your DynamoDB table

Evaluate your costs at the table level

The Cost Explorer tool found within the AWS Management Console allows you to see costs broken down by type, such as read, write, storage and backup charges. You can also see these costs summarized by period such as month or day.

One challenge administrators can face is when the costs of only one particular table need to be reviewed. Some of this data is available through the DynamoDB console or through calls to the `DescribeTable` API, however Cost Explorer does not, by default, allow you to filter or group by costs associated with a specific table. This section will show you how to use tagging to perform individual table cost analysis in Cost Explorer.

Topics

- How to view the costs of a single DynamoDB table
- Cost Explorer's default view
- How to use and apply table tags in Cost Explorer

How to view the costs of a single DynamoDB table

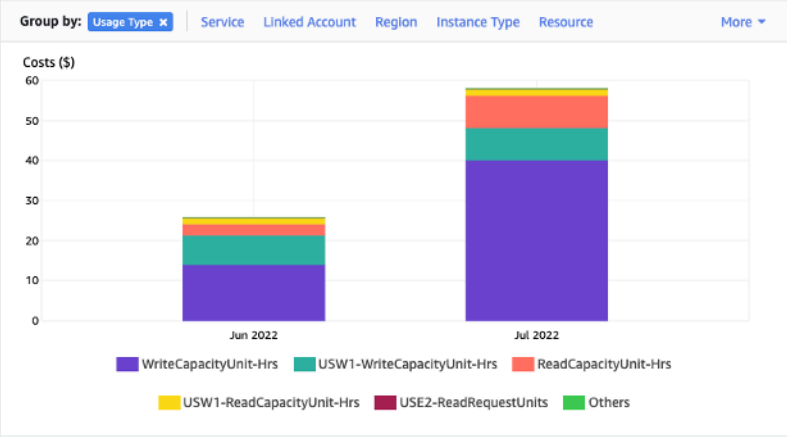
Both the Amazon DynamoDB AWS Management Console and the `DescribeTable` API will show you information about a single table, including the primary key schema, any indexes on the table, and the size and item count of the table and any indexes. The size of the table, plus the size of the indexes, can be used to calculate the monthly storage cost for your table. For example, $0.25 per GB in the us-east-1 region.

If the table is in provisioned capacity mode, the current RCU and WCU settings are returned as well. These could be used to calculate the current read and write costs for the table, but these costs could change, especially if the table has been configured with Auto Scaling.

> **Note**
>
> If the table is in on-demand capacity mode, then `DescribeTable` will not help estimate throughput costs, as these are billed based on actual, not provisioned usage in any one period.

Cost Explorer's default view

Cost Explorer's default view provides charts showing the cost of consumed resources such as throughput and storage. You can choose to group costs by period, such as totals by month or by day. The costs of storage, reads, writes, and other features can be broken out and compared as well.



How to use and apply table tags in Cost Explorer

By default, Cost Explorer does not provide a summary of the costs for any one specific table, as it will combine the costs of multiple tables into a total. However, you can use AWS resource tagging

to identify each table by a metadata tag. Tags are key-value pairs you can use for a variety of purposes, such as to identify all resources belonging to a project or department. For this example, we'll assume you have a table named **MyTable**.

1. Set a tag with the key of **table_name** and the value of **MyTable**.
2. Activate the tag within Cost Explorer and then filter on the tag value to gain more visibility into each table's costs.

> **Note**
>
> It might take one or two days for the tag to start appearing in Cost Explorer

You can set metadata tags yourself in the console, or through automation such as the AWS CLI or AWS SDK. Consider requiring a **table_name** tag to be set as part of your organization's new table creation process. For existing tables, there is a Python utility available that will find and apply these tags to all existing tables in a certain region in your account. See Eponymous Table Tagger on GitHub for more details.

Evaluate your DynamoDB table's capacity mode

This section provides an overview of how to select the appropriate capacity mode for your DynamoDB table. Each mode is tuned to meet the needs of a different workload in terms of responsiveness to change in throughput, as well as how that usage is billed. You must balance these factors when making your decision.

Topics

- What table capacity modes are available
- When to select on-demand capacity mode
- When to select provisioned capacity mode
- Additional factors to consider when choosing a table capacity mode

What table capacity modes are available

When you create a DynamoDB table, you must select either on-demand or provisioned capacity mode.

You can switch tables from provisioned capacity mode to on-demand mode up to four times in a 24-hour rolling window. You can switch tables from on-demand mode to provisioned capacity mode at any time.

On-demand capacity mode

The on-demand capacity mode is designed to eliminate the need to plan or provision the capacity of your DynamoDB table. In this mode, your table will instantly accommodate requests to your table without the need to scale any resources up or down (up to twice the previous peak throughput of the table).

DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you only pay for what you use.

Provisioned capacity mode

The provisioned capacity mode is a more traditional model where you must define how much capacity the table has available for requests either directly or with the assistance of auto scaling. Because a specific capacity is provisioned for the table at any given time, billing is based off of the total capacity provisioned rather than the number of requests consumed. Going over the allocated capacity can also cause the table to reject requests and reduce the experience of your applications users.

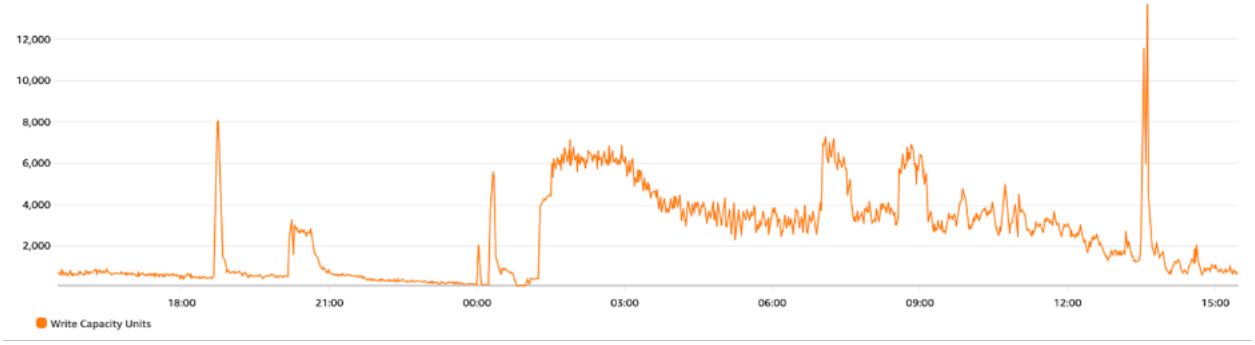
Provisioned capacity mode requires constant monitoring to find a balance between not over-provisioning or under-provisioning the table to keep both throttling low and costs tuned.

When to select on-demand capacity mode

When optimizing for cost, on-demand mode is your best choice when you have a workload similar to the following graphs.

The following factors contribute to this type of workload:

- Traffic pattern that evolves over time
- Variable volume of requests (resulting from batch workloads)
- Unpredictable request timing (resulting in traffic spikes)
- Drops to zero or below 30% of the peak for a given hour



For workloads with the above factors, using auto scaling to maintain enough capacity on the table to respond to spikes in traffic will likely lead to the table being overprovisioned and costing more than necessary or the table being under provisioned and requests being unnecessarily throttled. On-demand capacity mode is the better choice because it can handle fluctuating traffic without requiring you to predict or adjust capacity.

With on-demand mode's pay-per-request pricing model, you don't have to worry about idle capacity because you only pay for the throughput you actually use. You are billed per read or write request consumed, so your costs directly reflect your actual usage, making it easy to balance costs and performance. Optionally, you can also configure maximum read or write (or both) throughput per second for individual on-demand tables and global secondary indexes to help keep costs and usage bounded. For more information, see maximum throughput for on-demand tables .

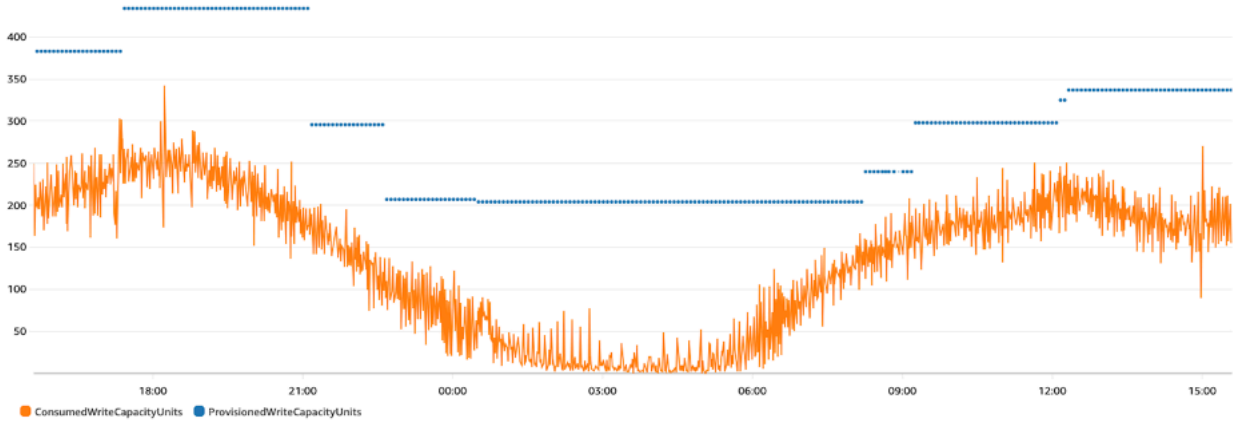
When to select provisioned capacity mode

An ideal workload for provisioned capacity mode is one with a more steady and predictable usage pattern like the graph below.

> **Note**
>
> We recommend reviewing metrics at a fine-grained period, such as 14 days, before taking action on your provisioned capacity.

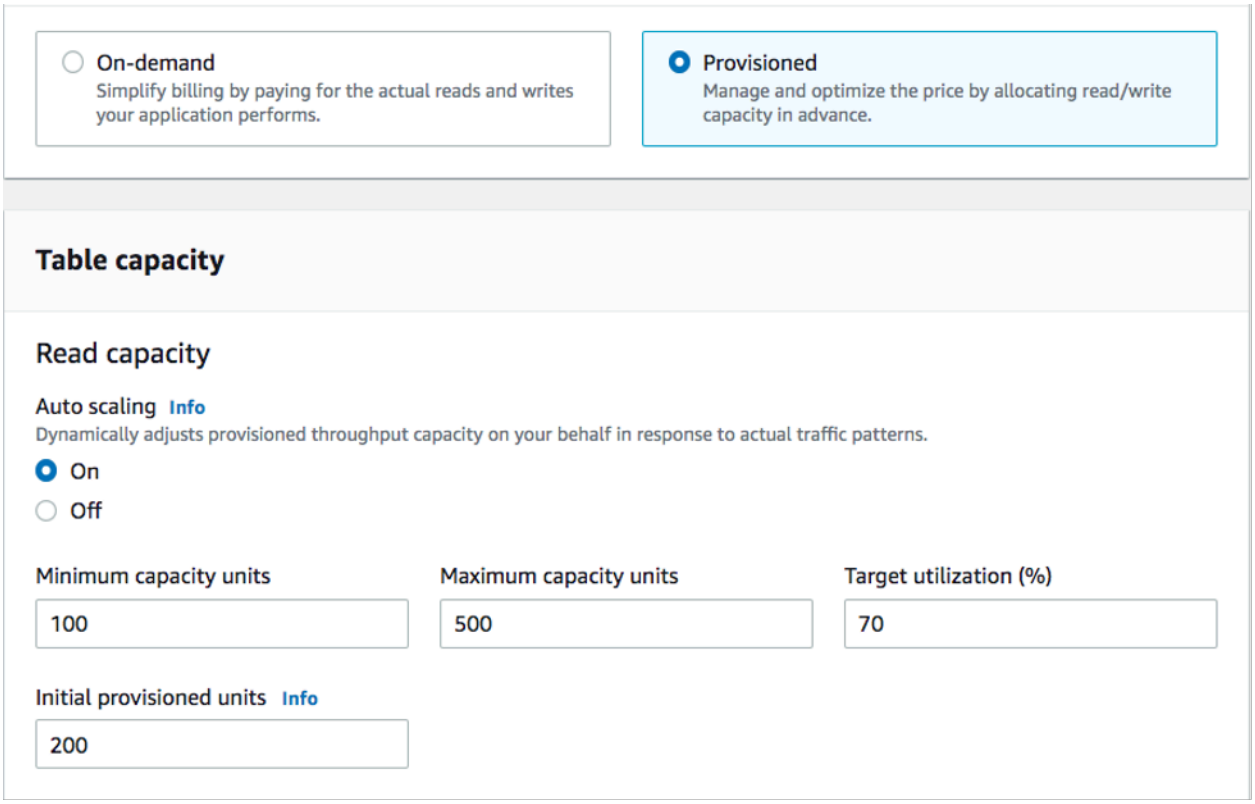
The following factors contribute to this type of workload:

- Steady, predictable and cyclical traffic for a given hour or day
- Limited short-term bursts of traffic



Since the traffic volumes within a given hour or day are more stable, you can set the provisioned capacity of the table relatively close to the actual consumed capacity of the table. Cost optimizing a provisioned capacity table is ultimately an exercise in getting the provisioned capacity (blue line) as close to the consumed capacity (orange line) as possible without increasing `ThrottledRequests` on the table. The space between the two lines is both wasted capacity as well as insurance against a bad user experience due to throttling. If you can predict your application's throughput requirements and you prefer the cost predictability of controlling read and write capacity, then you might want to continue using provisioned tables.

DynamoDB provides auto scaling for provisioned capacity tables which will automatically balance this on your behalf. This lets you track your consumed capacity throughout the day and set the capacity of the table based on a handful of variables. When using auto scaling, your table will be over-provisioned and you need to fine tune the ratio between number of throttles versus over-provisioned capacity units to match your workload needs.



Minimum capacity units

You can set the minimum capacity of a table to limit throttling, but it will not reduce the cost of the table. If your table has periods of low usage follow by a sudden burst of high usage, setting the minimum can prevent auto scaling from setting the table capacity too low.

Maximum capacity units

You can set the maximum capacity of a table to limit a table scaling higher than intended. Consider applying a maximum for Dev or Test tables where large-scale load testing is not desired. You can set a maximum for any table, but be sure to regularly evaluate this setting against the table baseline when using it in Production to prevent accidental throttling.

Target utilization

Setting the target utilization of the table is the primary means of cost optimization for a provisioned capacity table. Setting a lower percent value here will increase how much the table is overprovisioned, increasing cost, but reducing the risk of throttling. Setting a higher percent value will decrease how much the table is overprovisioned, but increase the risk of throttling.

Additional factors to consider when choosing a table capacity mode

When deciding between the two modes, there are some additional factors worth considering.

Provisioned capacity utilization

To determine when on-demand mode would cost less than provisioned capacity, it's helpful to look at your provisioned capacity utilization, which refers to how efficiently the allocated (or “provisioned) resources are being used. On-demand mode costs less for workloads with average provisioned capacity utilization below 35%. In many cases, even for workloads with provisioned capacity utilization higher than 35%, it can be more cost-effective to use on-demand mode especially if the workload has periods of low activity mixed with occasional peaks.

Reserved capacity

For provisioned capacity tables, DynamoDB offers the ability to purchase reserved capacity for your read and write capacity (replicated write capacity units (rWCU) and Standard-IA tables are currently not eligible). Reserved capacity offers significant discounts over standard provisioned capacity pricing.

When deciding between the two table modes, consider how much this additional discount will affect the cost of the table. In some cases, it might cost less to run a relatively unpredictable workload can be cheaper to run on an overprovisioned provisioned capacity table with reserved capacity.

Improving predictability of your workload

In some situations, a workload might seemingly have both a predictable and unpredictable pattern. While this can be easily supported with an on-demand table, costs will likely be better if the unpredictable patterns in the workload can be improved.

One of the most common causes of these patterns is batch imports. This type of traffic can often exceed the baseline capacity of the table to such a degree that throttling would occur if it were to run. To keep a workload like this running on a provisioned capacity table, consider the following options:

- If the batch occurs at scheduled times, you can schedule an increase to your auto- scaling capacity before it runs
- If the batch occurs randomly, consider trying to extend the time it runs rather than executing as fast as possible

- Add a ramp up period to the import where the velocity of the import starts small but is slowly increased over a few minutes until auto scaling has had the opportunity to start adjusting table capacity

Evaluate your DynamoDB table's auto scaling settings

This section provides an overview of how to evaluate the auto scaling settings on your DynamoDB tables. Amazon DynamoDB auto scaling is a feature that manages table and global secondary index (GSI) throughput based on your application traffic and your target utilization metric. This ensures your tables or GSIs will have the required capacity required for your application patterns.

The AWS auto scaling service will monitor your current table utilization and compare it to the target utilization value: `TargetValue`. It will notify you if it is time to increase or decrease the capacity allocated.

Topics

- Understanding your auto scaling settings
- How to identify tables with low target utilization (<=50%)
- How to address workloads with seasonal variance
- How to address spiky workloads with unknown patterns
- How to address workloads with linked applications

Understanding your auto scaling settings

Defining the correct value for the target utilization, initial step, and final values is an activity that requires involvement from your operations team. This allows you to properly define the values based on historical application usage, which will be used to trigger the AWS auto scaling policies. The utilization target is the percentage of your total capacity that needs to be hit during a period of time before the auto scaling rules apply.

When you set a **high utilization target (a target around 90%)** it means your traffic needs to be higher than 90% for a period of time before the auto scaling kicks in. You should not use a high utilization target unless your application is very constant and doesn't receive spikes in traffic.

When you set a very **low utilization (a target less than 50%)** it means your application would need to reach 50% of the provisioned capacity before it triggers an auto scaling policy. Unless your

application traffic grows at a very aggressive rate, this usually translates into unused capacity and wasted resources.

How to identify tables with low target utilization (<=50%)

You can use either the AWS CLI or AWS Management Console to monitor and identify the `TargetValues` for your auto scaling policies in your DynamoDB resources:

AWS CLI

1. Return the entire list of resources by running the following command:

   ```
   aws application-autoscaling describe-scaling-policies --service-namespace
    dynamodb
   ```

   This command will return the entire list of auto scaling policies that are issued to any DynamoDB resource. If you only want to retrieve the resources from a particular table, you can add the `–resource-id parameter`. For example:

   ```
   aws application-autoscaling describe-scaling-policies --service-namespace
    dynamodb --resource-id "table/<table-name>”
   ```

2. Return only the auto scaling policies for a particular GSI by running the following command

   ```
   aws application-autoscaling describe-scaling-policies --service-namespace
    dynamodb --resource-id "table/<table-name>/index/<gsi-name>”
   ```

   The values we're interested in for the auto scaling policies are highlighted below. We want to make sure that the target value is greater than 50% to avoid over-provisioning. You should obtain a result similar to the following:

   ```
   {
       "ScalingPolicies": [
           {
               "PolicyARN": "arn:aws:autoscaling:<region>:<account-
   id>:scalingPolicy:<uuid>:resource/dynamodb/table/<table-name>/index/<index-
   name>:policyName/$<full-gsi-name>-scaling-policy",
               "PolicyName": $<full-gsi-name>”,
               "ServiceNamespace": "dynamodb",
               "ResourceId": "table/<table-name>/index/<index-name>",
               "ScalableDimension": "dynamodb:index:WriteCapacityUnits",
   ```

```
            "PolicyType": "TargetTrackingScaling",
            "TargetTrackingScalingPolicyConfiguration": {
                "TargetValue": 70.0,
                "PredefinedMetricSpecification": {
                    "PredefinedMetricType": "DynamoDBWriteCapacityUtilization"
                }
            },
            "Alarms": [
                ...
            ],
            "CreationTime": "2022-03-04T16:23:48.641000+10:00"
        },
        {
            "PolicyARN": "arn:aws:autoscaling:<region>:<account-

        }
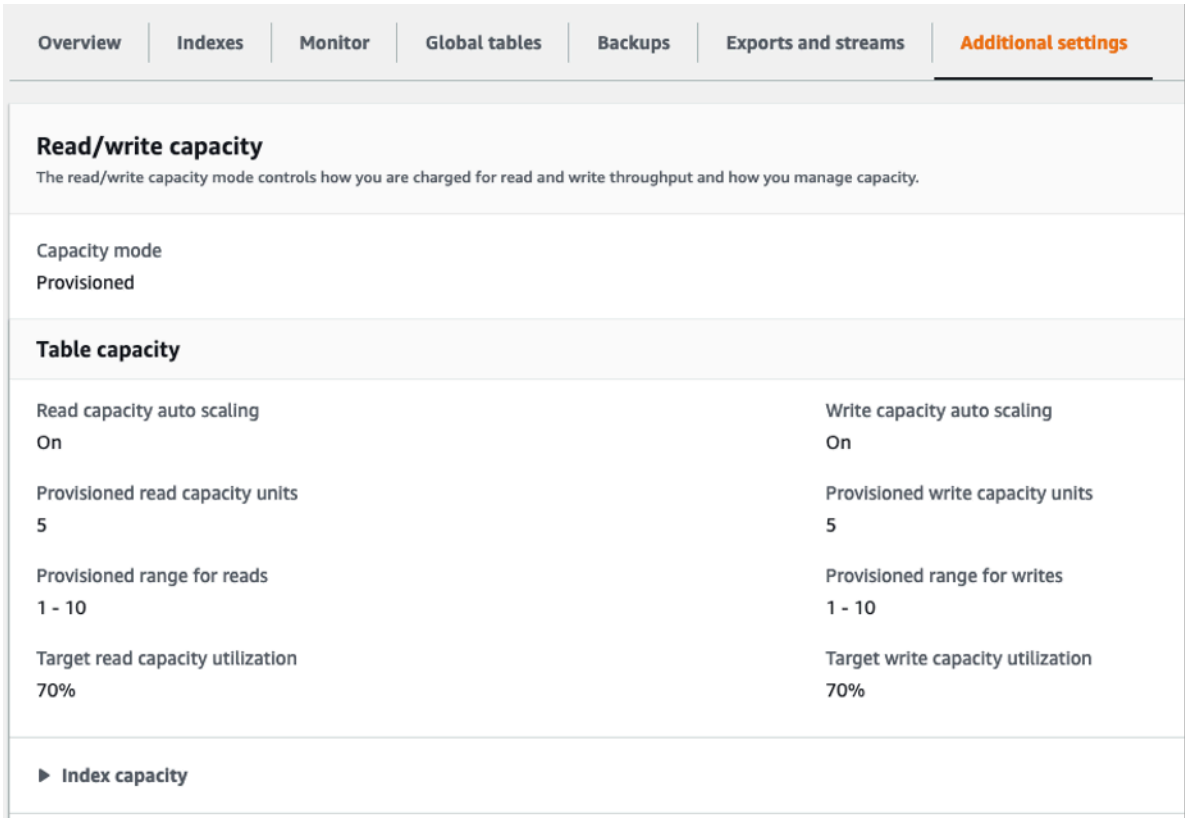
    ]
}
```

AWS Management Console

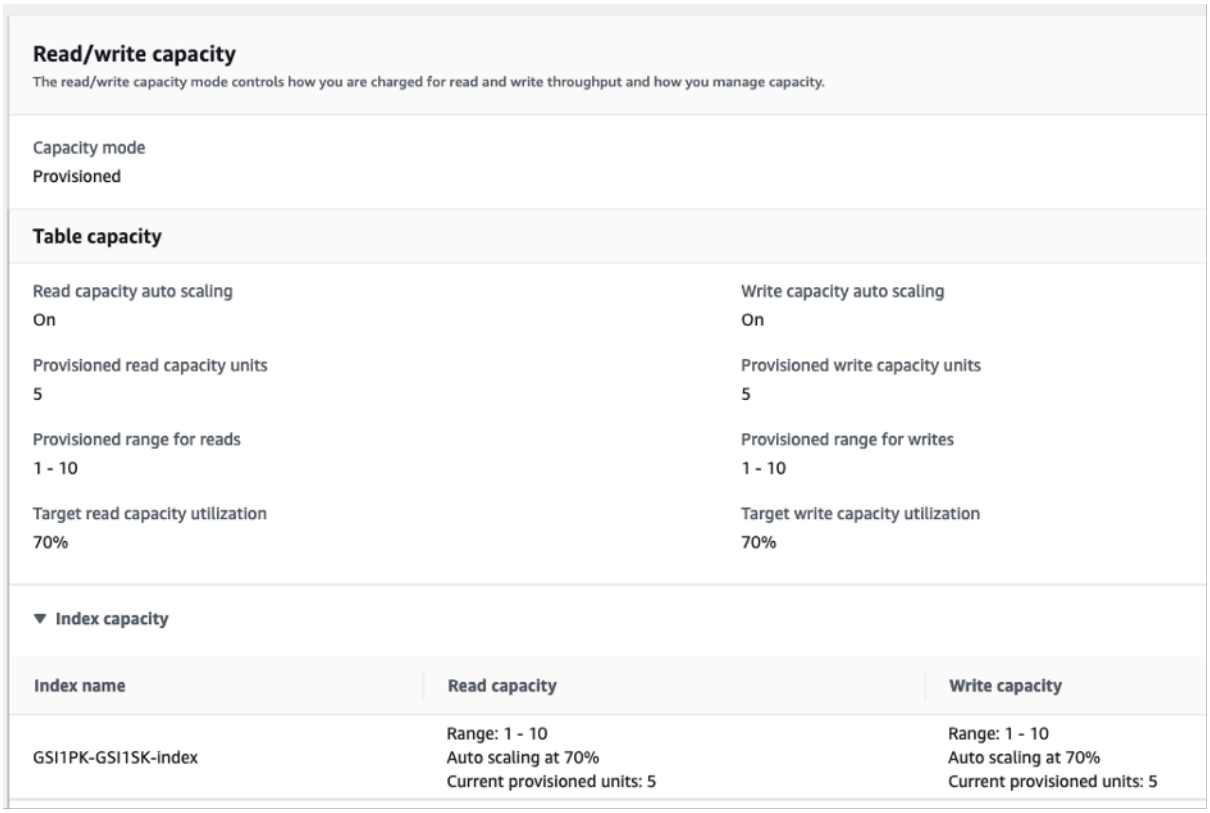
1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.

   Select an appropriate AWS Region if necessary.

2. On the left navigation bar, select **Tables**. On the **Tables** page, select the table's **Name**.
3. On the *Table details* page, choose **Additional settings**, and then review your table's auto scaling settings.



For indexes, expand the **Index capacity** section to review the index's auto scaling settings.



If your target utilization values are less than or equal to 50%, you should explore your table utilization metrics to see if they are under-provisioned or over-provisioned.

How to address workloads with seasonal variance

Consider the following scenario: your application is operating under a minimum average value most of the time, but the utilization target is low so your application can react quickly to events that happen at certain hours in the day and you have enough capacity and avoid getting throttled. This scenario is common when you have an application that is very busy during normal office hours (9 AM to 5 PM) but then it works at a base level during after hours. Since some users will start to connect before 9 am, the application uses this low threshold to ramp up quickly to get to the *required* capacity during peak hours.

This scenario could look like this:

- Between 5 PM and 9 AM the `ConsumedWriteCapacity` units stay between 90 and 100
- Users start to connect to the application before 9 AM and the capacity units increases considerably (the maximum value you've seen is 1500 WCU)
- On average, your application usage varies between 800 to 1200 during working hours

If the previous scenario applies to you, consider using scheduled auto scaling, where your table could still have an application auto scaling rule configured, but with a less aggressive target utilization that only provisions the extra capacity at the specific intervals you require.

You can use AWS CLI to execute the following steps to create a scheduled auto scaling rule that will execute based on the time of day and the day of the week.

1. Register your DynamoDB table or GSI as scalable target with Application Auto Scaling. A scalable target is a resource that Application Auto Scaling can scale out or in.

```
aws application-autoscaling register-scalable-target \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:WriteCapacityUnits \
    --resource-id table/<table-name> \
    --min-capacity 90 \
    --max-capacity 1500
```

2. Set up scheduled actions according to your requirements.

   We'll need two rules to cover the scenario: one to scale up and another to scale down. The first rule to scale up the scheduled action:

```
aws application-autoscaling put-scheduled-action \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:WriteCapacityUnits \
    --resource-id table/<table-name> \
    --scheduled-action-name my-8-5-scheduled-action \
    --scalable-target-action MinCapacity=800,MaxCapacity=1500 \
    --schedule "cron(45 8 ? * MON-FRI *)" \
    --timezone "Australia/Brisbane"
```

   The second rule to scale down the scheduled action:

```
aws application-autoscaling put-scheduled-action \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:WriteCapacityUnits \
    --resource-id table/<table-name> \
    --scheduled-action-name my-5-8-scheduled-down-action \
    --scalable-target-action MinCapacity=90,MaxCapacity=1500 \
    --schedule "cron(15 17 ? * MON-FRI *)" \
    --timezone "Australia/Brisbane"
```

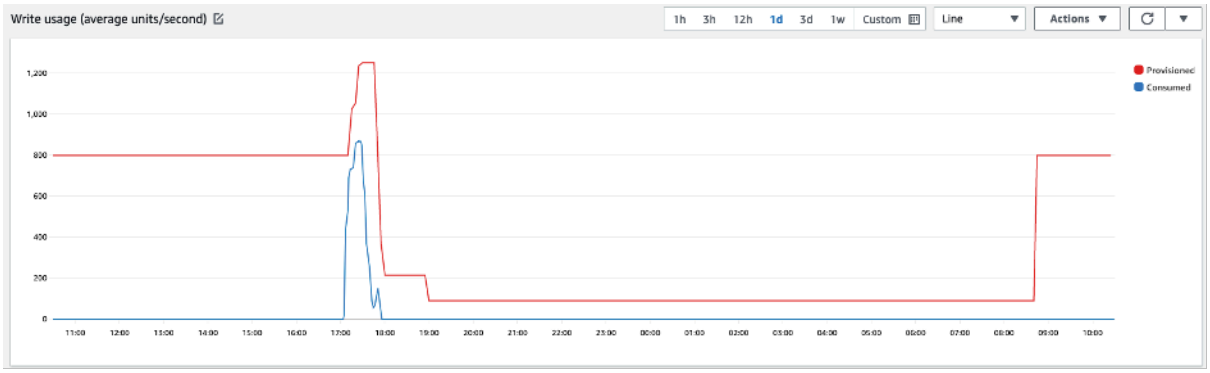
3. Run the following command to validate both rules have been activated:

```
aws application-autoscaling describe-scheduled-actions --service-namespace dynamodb
```

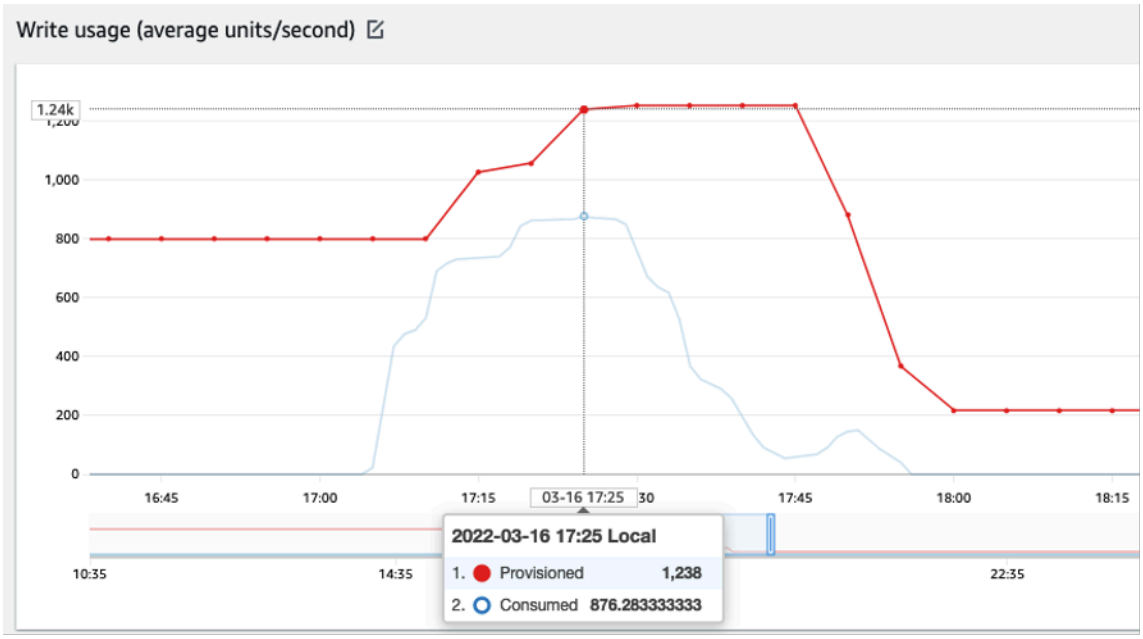
You should get a result like this:

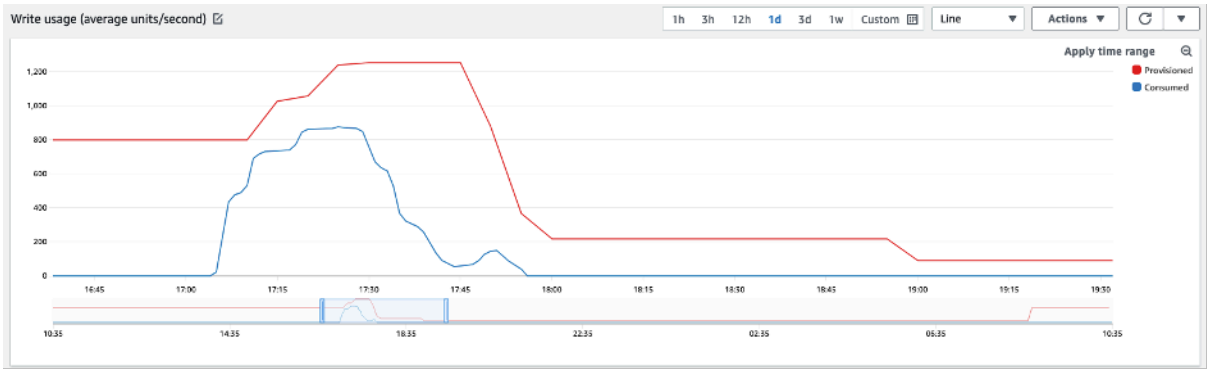
```
{
    "ScheduledActions": [
        {
            "ScheduledActionName": "my-5-8-scheduled-down-action",
            "ScheduledActionARN":
 "arn:aws:autoscaling:<region>:<account>:scheduledAction:<uuid>:resource/dynamodb/
table/<table-name>:scheduledActionName/my-5-8-scheduled-down-action",
            "ServiceNamespace": "dynamodb",
            "Schedule": "cron(15 17 ? * MON-FRI *)",
            "Timezone": "Australia/Brisbane",
            "ResourceId": "table/<table-name>",
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "ScalableTargetAction": {
                "MinCapacity": 90,
                "MaxCapacity": 1500
            },
            "CreationTime": "2022-03-15T17:30:25.100000+10:00"
        },
        {
            "ScheduledActionName": "my-8-5-scheduled-action",
            "ScheduledActionARN":
 "arn:aws:autoscaling:<region>:<account>:scheduledAction:<uuid>:resource/dynamodb/
table/<table-name>:scheduledActionName/my-8-5-scheduled-action",
            "ServiceNamespace": "dynamodb",
            "Schedule": "cron(45 8 ? * MON-FRI *)",
            "Timezone": "Australia/Brisbane",
            "ResourceId": "table/<table-name>",
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "ScalableTargetAction": {
                "MinCapacity": 800,
                "MaxCapacity": 1500
            },
            "CreationTime": "2022-03-15T17:28:57.816000+10:00"
        }
    ]
}
```

The following picture shows a sample workload that always keeps the 70% target utilization. Notice how the auto scaling rules are still applying and the throughput will not be reduced.



Zooming in, you can see there was a spike in the application that triggered the 70% auto scaling threshold, forcing the auto scaling to kick in and provide the extra capacity required for the table. The scheduled auto scaling action will affect maximum and minimum values, and it is your responsibility to set them up.





How to address spiky workloads with unknown patterns

In this scenario, the application uses a very low utilization target because you don't know the application patterns yet, and you want to make sure your workload is not throttled.

Consider using on-demand capacity mode instead. On-demand tables are perfect for spiky workloads where you don't know the traffic patterns. With on-demand capacity mode, you pay per request for the data reads and writes your application performs on your tables. You do not need to specify how much read and write throughput you expect your application to perform, as DynamoDB instantly accommodates your workloads as they ramp up or down.

How to address workloads with linked applications

In this scenario, the application depends on other systems, like batch processing scenarios where you can have big spikes in traffic according to events in the application logic.

Consider developing custom auto scaling logic that reacts to those events where you can increase table capacity and `TargetValues` depending on your specific needs. You could benefit from Amazon EventBridge and use a combination of AWS services like Lambda and Step Functions to react to your specific application needs.

Evaluate your DynamoDB table class selection

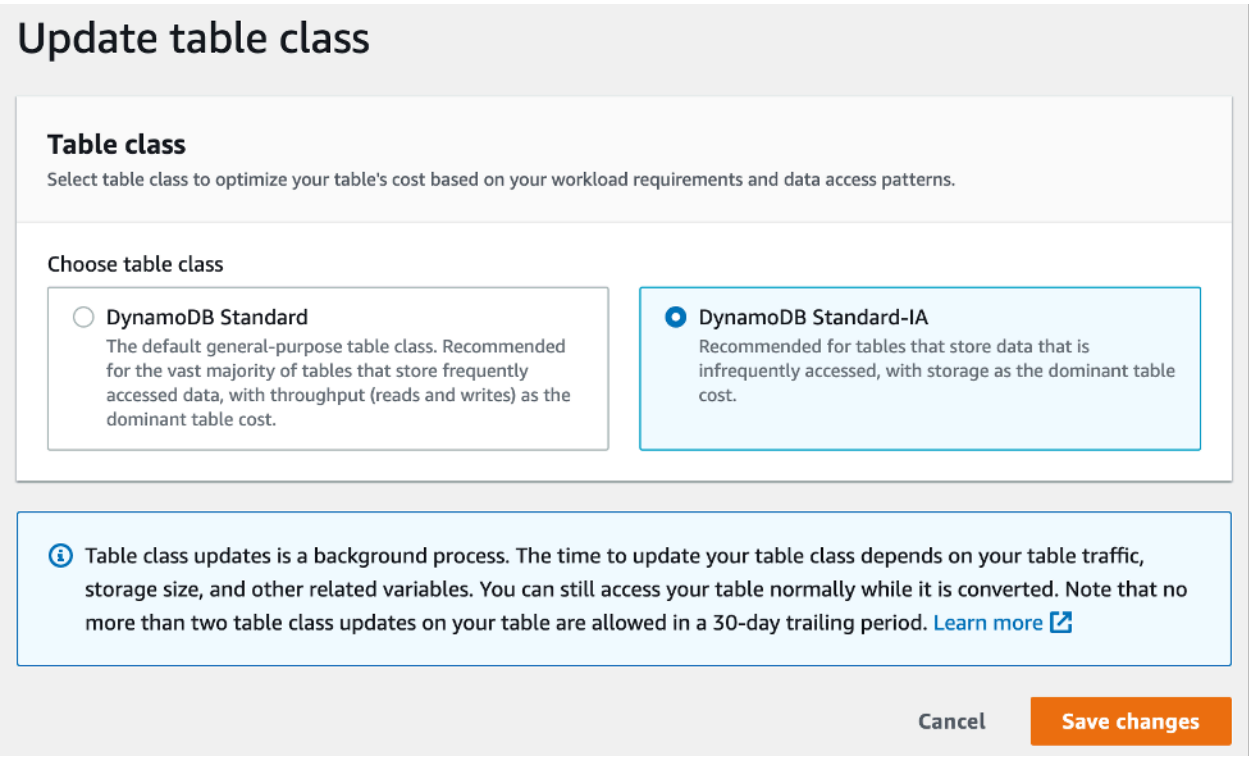
This section provides an overview of how to select the appropriate table class for your DynamoDB table. With the launch of the Standard Infrequent-Access (Standard-IA) table class, you now have the ability to optimize a table for either lower storage cost or lower throughput cost.

Topics

- What table classes are available
- When to select the DynamoDB Standard table class
- When to select DynamoDB Standard-IA table class
- Additional factors to consider when choosing a table class

What table classes are available

When you create a DynamoDB Table, you must select either DynamoDB Standard or DynamoDB Standard-IA for the table class. The table class can be changed twice in a 30-day period, so you can always change it in the future. Selecting either table class has no effect on table performance, availability, reliability, or durability.



Standard table class

The Standard table class is the default option for new tables. This option maintains the original billing balance of DynamoDB which offers a balance of throughput and storage costs for tables with frequently accessed data.

Standard-IA table class

The Standard-IA table class offers a lower storage cost (~60% lower) for workloads that require long-term storage of data with infrequent updates or reads. Since the class is optimized for infrequent access, reads and writes will be billed at a slightly higher cost (~25% higher) than the Standard table class.

When to select the DynamoDB Standard table class

DynamoDB Standard table class is best suited for tables whose storage cost is approximately 50% or less of the overall monthly cost of the table. This cost balance is indicative of a workload that regularly accesses or updates items already stored within DynamoDB.

When to select DynamoDB Standard-IA table class

DynamoDB Standard-IA table class is best suited for tables whose storage cost is approximately 50% or more of the overall monthly cost of the table. This cost balance is indicative of a workload that creates or reads fewer items per month than it keeps in storage.

A common use for the Standard-IA table class is moving less frequently accessed data to individual Standard-IA tables. For further information, see Optimizing the storage costs of your workloads with Amazon DynamoDB Standard-IA table class.

Additional factors to consider when choosing a table class

When deciding between the two table classes, there are some additional factors worth considering as part of your decision.

Reserved capacity

Purchasing reserved capacity for tables using the Standard-IA table class is currently not supported. When transitioning from a Standard table with reserved capacity to a Standard-IA table without reserved capacity, you might not see a cost benefit.

Identify your unused resources in DynamoDB

This section provides an overview of how to evaluate your unused resources regularly. As your application requirements evolve you should make sure no resources are unused and contributing to unnecessary Amazon DynamoDB costs. The procedures described below will use Amazon CloudWatch metrics to identify unused resources and will help you identify and take action on those resources to reduce costs.

You can monitor DynamoDB using CloudWatch, which collects and processes raw data from DynamoDB into readable, near real-time metrics. These statistics are retained for a period of time, so that you can access historical information to better understand your utilization. By default, DynamoDB metric data is sent to CloudWatch automatically. For more information, see What is Amazon CloudWatch? and Metrics retention in the *Amazon CloudWatch User Guide*.

Topics

- How to identify unused resources
- Identifying unused table resources
- Cleaning up unused table resources

- Identifying unused GSI resources
- Cleaning up unused GSI resources
- Cleaning up unused global tables
- Cleaning up unused backups or point-in-time recovery (PITR)

How to identify unused resources

To identify unused tables or indexes, we'll look at the following CloudWatch metrics over a period of 30 days to understand if there are any active reads or writes on the table or any reads on the global secondary indexes (GSIs):

ConsumedReadCapacityUnits

The number of read capacity units consumed over the specified time period, so you can track how much consumed capacity you have used. You can retrieve the total consumed read capacity for a table and all of its global secondary indexes, or for a particular global secondary index.

ConsumedWriteCapacityUnits

The number of write capacity units consumed over the specified time period, so you can track how much consumed capacity you have used. You can retrieve the total consumed write capacity for a table and all of its global secondary indexes, or for a particular global secondary index.

Identifying unused table resources

Amazon CloudWatch is a monitoring and observability service which provides the DynamoDB table metrics you'll use to identify unused resources. CloudWatch metrics can be viewed through the AWS Management Console as well as through the AWS Command Line Interface.

AWS Command Line Interface

To view your tables metrics through the AWS Command Line Interface, you can use the following commands.

1. First, evaluate your table's reads:

```
aws cloudwatch get-metric-statistics --metric-name
ConsumedReadCapacityUnits --start-time <start-time> --end-time <end-
time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
```

```
dimensions Name=TableName,Value=<table-name>
```

To avoid falsely identifying a table as unused, evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as **30 days**, and an appropriate period, such as **86400**.

In the returned data, any **Sum** above **0** indicates that the table you are evaluating received read traffic during that period.

The following result shows a table receiving read traffic in the evaluated period:

```
        {
            "Timestamp": "2022-08-25T19:40:00Z",
            "Sum": 36023355.0,
            "Unit": "Count"
        },
        {
            "Timestamp": "2022-08-12T19:40:00Z",
            "Sum": 38025777.5,
            "Unit": "Count"
        },
```

The following result shows a table not receiving read traffic in the evaluated period:

```
        {
            "Timestamp": "2022-08-01T19:50:00Z",
            "Sum": 0.0,
            "Unit": "Count"
        },
        {
            "Timestamp": "2022-08-20T19:50:00Z",
            "Sum": 0.0,
            "Unit": "Count"
        },
```

2. Next, evaluate your table's writes:

```
aws cloudwatch get-metric-statistics --metric-name
ConsumedWriteCapacityUnits --start-time <start-time> --end-time <end-
time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
dimensions Name=TableName,Value=<table-name>
```

To avoid falsely identifying a table as unused, you will want to evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as **30 days**, and an appropriate period, such as **86400**.

In the returned data, any **Sum** above **0** indicates that the table you are evaluating received read traffic during that period.

The following result shows a table receiving write traffic in the evaluated period:

```
{
    "Timestamp": "2022-08-19T20:15:00Z",
    "Sum": 41014457.0,
    "Unit": "Count"
},
{
    "Timestamp": "2022-08-18T20:15:00Z",
    "Sum": 40048531.0,
    "Unit": "Count"
},
```

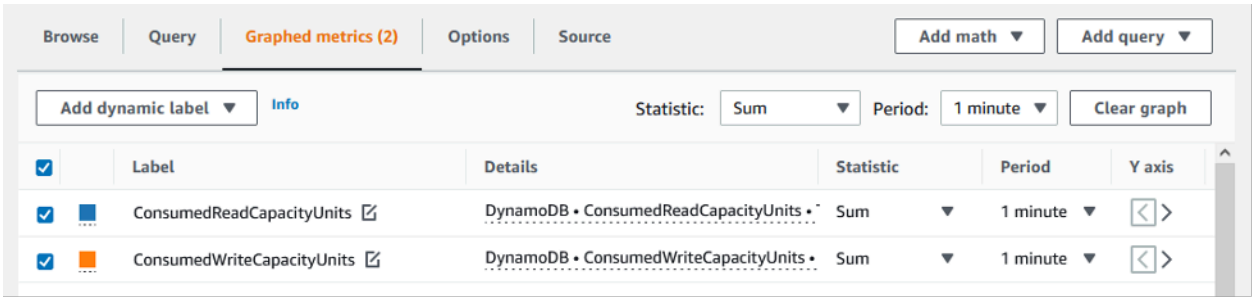
The following result shows a table not receiving write traffic in the evaluated period:

```
{
    "Timestamp": "2022-07-31T20:15:00Z",
    "Sum": 0.0,
    "Unit": "Count"
},
{
    "Timestamp": "2022-08-19T20:15:00Z",
    "Sum": 0.0,
    "Unit": "Count"
},
```

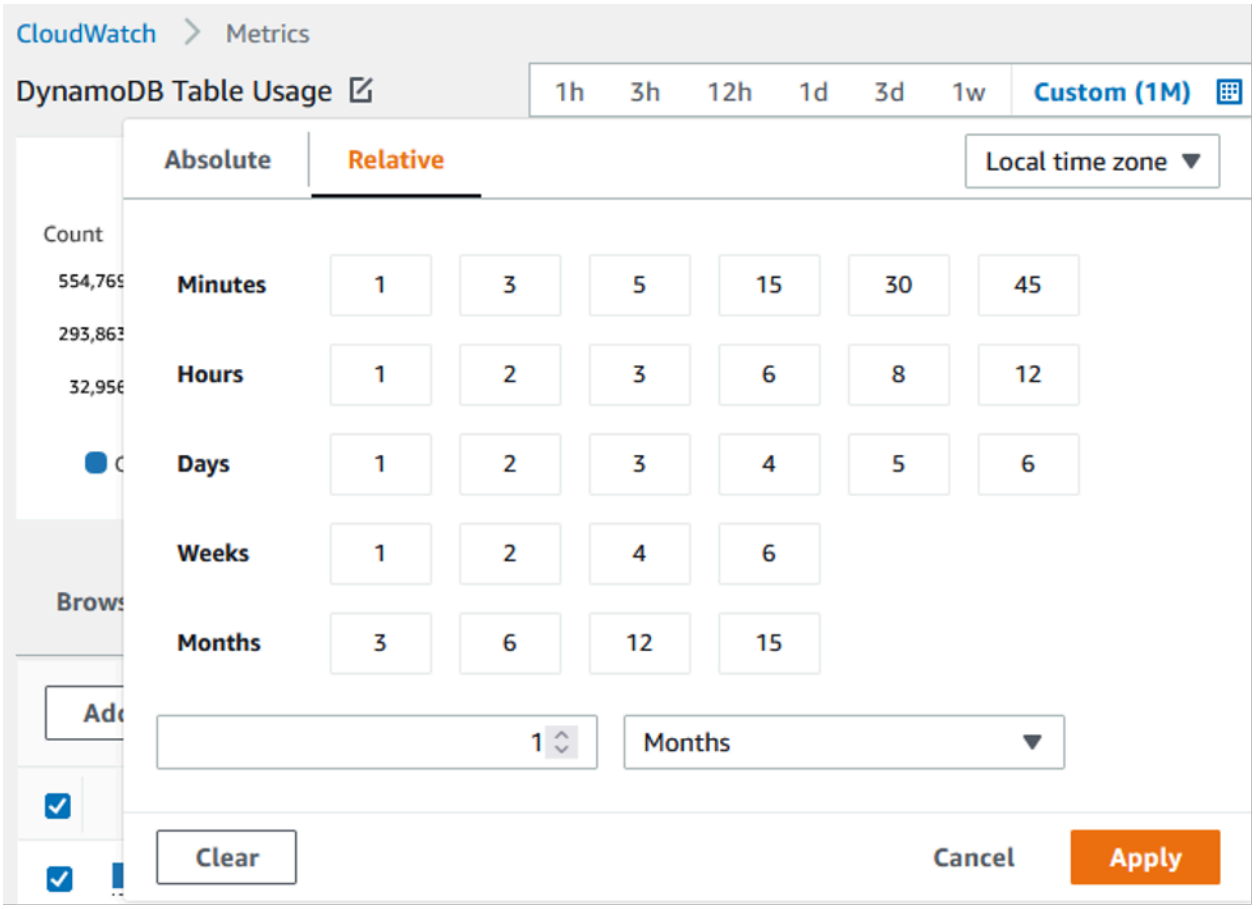
AWS Management Console

The following steps will allow you to evaluate your resources utilization through the AWS Management Console.

1. Log into the AWS console and navigate to the CloudWatch service page at https://console.aws.amazon.com/cloudwatch/. Select the appropriate AWS region in the top right of the console, if necessary.
2. On the left navigation bar, locate the Metrics section and select **All metrics**.
3. The action above will open a dashboard with two panels. In the top panel you will see currently graphed metrics. In the bottom you will select the metrics available to graph. Select DynamoDB in the bottom panel.
4. In the DynamoDB metrics selection panel select the **Table Metrics** category to show the metrics for your tables in the current region.
5. Identify your table name by scrolling down the menu, then select the metrics `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` for your table.
6. Select the **Graphed metrics (2)** tab and adjust the **Statistic** column to **Sum**.



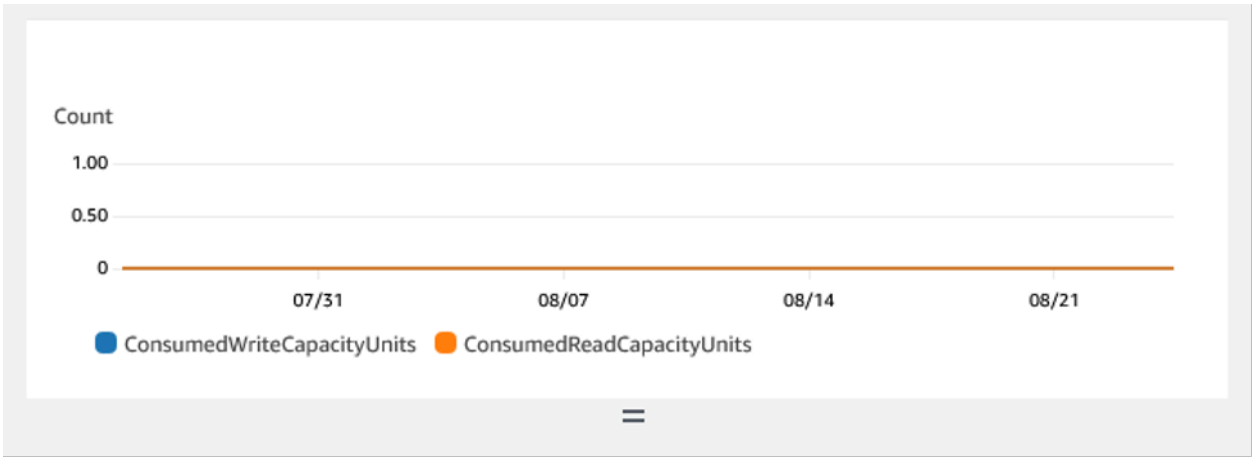
7. To avoid falsely identifying a table as unused, you'll want to evaluate metrics over a longer period. At the top of the graph panel choose an appropriate time frame, such as 1 month, to evaluate your table. Select **Custom**, select **1 Months** in the dropdowns, and choose **Apply**.



8. Evaluate the graphed metrics for your table to determine if it is being used. Metrics that have gone above **0** indicate that a table has been used during the evaluated time period. A flat graph at **0** for both read and write indicates a table that is unused.

   The following image shows a table with read traffic:

   The following image shows a table without read traffic:



Cleaning up unused table resources

If you have identified unused table resources, you can reduce their ongoing costs in the following ways.

> **Note**
>
> If you have identified an unused table but would still like to keep it available in case it needs to be accessed in the future, consider switching it to on-demand mode. Otherwise, you can consider backing up and deleting the table entirely.

Capacity modes

DynamoDB charges for reading, writing, and storing data in your DynamoDB tables.

DynamoDB has two capacity modes, which come with specific billing options for processing reads and writes on your tables: on-demand and provisioned. The read/write capacity mode controls how you are charged for read and write throughput and how you manage capacity.

For on-demand mode tables, you don't need to specify how much read and write throughput you expect your application to perform. DynamoDB charges you for the reads and writes that your application performs on your tables in terms of read request units and write request units. If there is no activity on your table/index you do not pay for throughput but you'll still incur a storage charge.

Table class

DynamoDB also offers two table classes designed to help you optimize for cost. The DynamoDB Standard table class is the default and is recommended for most workloads. The DynamoDB Standard-Infrequent Access (DynamoDB Standard-IA) table class is optimized for tables where storage is the dominant cost.

If there is no activity on your table or index, storage is likely to be the dominant cost and changing table class will offer a significant savings.

Deleting tables

If you've discovered an unused table and would like to delete it, you may wish to make a backup or export of the data first.

Backups taken through AWS Backup can leverage cold storage tiering, further reducing costs. Refer to the Using AWS Backup with DynamoDB documentation for information on how enable backups through AWS Backup as well as the Managing backup plans documentation for information on how to use lifecycle to move your backup to cold storage.

Alternatively, you may choose to export your table's data to S3. To do so, refer to the Export to Amazon S3 documentation. Once your data is exported, if you wish to leverage S3 Glacier Instant Retrieval, S3 Glacier Flexile Retrieval, or S3 Glacier Deep Archive to further reduce costs, see Managing your storage lifecycle.

After your table has been backed up, you may choose to delete it either through the AWS Management Console or through the AWS Command Line Interface.

Identifying unused GSI resources

The steps for identifying an unused global secondary are similar to those for identifying an unused table. Since DynamoDB replicates items written to your base table into your GSI if they contain the attribute used as the GSI's partition key, an unused GSI is still likely to have `ConsumedWriteCapacityUnits` above 0 if its base table is in use. As a result, you'll be evaluating only the `ConsumedReadCapacityUnits` metric to determine if your GSI is unused.

To view your GSI metrics through the AWS AWS CLI, you can use the following commands to evaluate your tables reads:

```
aws cloudwatch get-metric-statistics --metric-name
ConsumedReadCapacityUnits --start-time <start-time> --end-time <end-
time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
dimensions Name=TableName,Value=<table-name>
```

```
Name=GlobalSecondaryIndexName,Value=<index-name>
```

To avoid falsely identifying a table as unused, you will want to evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as 30 days, and an appropriate period, such as 86400.

In the returned data, any Sum above 0 indicates that the table you are evaluating received read traffic during that period.

The following result shows a GSI receiving read traffic in the evaluated period:

```
        {
          "Timestamp": "2022-08-17T21:20:00Z",
          "Sum": 36319167.0,
          "Unit": "Count"
        },
        {
          "Timestamp": "2022-08-11T21:20:00Z",
          "Sum": 1869136.0,
          "Unit": "Count"
        },
```

The following result shows a GSI receiving minimal read traffic in the evaluated period:

```
        {
          "Timestamp": "2022-08-28T21:20:00Z",
          "Sum": 0.0,
          "Unit": "Count"
        },
        {
          "Timestamp": "2022-08-15T21:20:00Z",
          "Sum": 2.0,
          "Unit": "Count"
        },
```

The following result shows a GSI receiving no read traffic in the evaluated period:

```
        {
          "Timestamp": "2022-08-17T21:20:00Z",
          "Sum": 0.0,
          "Unit": "Count"
        },
```

```
        {
          "Timestamp": "2022-08-11T21:20:00Z",
          "Sum": 0.0,
          "Unit": "Count"
        },
```

Cleaning up unused GSI resources

If you've identified an unused GSI, you can choose to delete it. Since all data present in a GSI is also present in the base table, additional backup is not necessary before deleting a GSI. If in the future the GSI is once again needed, it may be added back to the table.

If you have identified an infrequently used GSI, you should consider design changes in your application that would allow you to delete it or reduce its cost. For example, while DynamoDB scans should be used sparingly because they can consume large amounts of system resources, they may be more cost effective than a GSI if the access pattern it supports is used very infrequently.

Additionally, if a GSI is required to support an infrequent access pattern consider projecting a more limited set of attributes. While this may require subsequent queries against the base table to support your infrequent access patterns, it can potentially offer a significant reduction in storage and write costs.

Cleaning up unused global tables

Amazon DynamoDB global tables provide a fully managed solution for deploying a multi-Region, multi-active database, without having to build and maintain your own replication solution.

Global tables are ideal for providing low-latency access to data close to users and as well as a secondary region for disaster recovery.

If the global tables option is enabled for a resource in an effort to provide low-latency access to data but is not part of your disaster recovery strategy, validate that both replicas are actively serving read traffic by evaluating their CloudWatch metrics. If one replica does not serve read traffic, it may be an unused resource.

If global tables are part of your disaster recovery strategy, one replica not receiving read traffic may be expected under an active/standby pattern.

Cleaning up unused backups or point-in-time recovery (PITR)

DynamoDB offers two styles of backup. Point-in-time recovery provides continuous backups for up to 35 days to help you protect against accidental writes or deletes while on-demand backup allows

for snapshot creation which can be saved long term. You can set the recovery period to any value between 1 and 35 days. Both types of backups have costs associated with them.

Refer to the documentation for Backup and restore for DynamoDB and Point-in-time backups for DynamoDB to determine if your tables have backups enabled that may no longer be needed.

Evaluate your DynamoDB table usage patterns

This section provides an overview of how to evaluate if you are efficiently using your DynamoDB tables. There are certain usage patterns which are not optimal for DynamoDB, and they allow room for optimization from both a performance and cost perspective.

Topics

- Perform fewer strongly-consistent read operations
- Perform fewer transactions for read operations
- Perform fewer scans
- Shorten attribute names
- Enable Time to Live (TTL)
- Replace global tables with cross-Region backups

Perform fewer strongly-consistent read operations

DynamoDB allows you to configure read consistency on a per-request basis. Read requests are eventually consistent by default. Eventually consistent reads are charged at 0.5 RCU for upto 4 KB of data.

Most parts of distributed workloads are flexible and can tolerate eventual consistency. However, there can be access patterns requiring strongly consistent reads. Strongly consistent reads are charged at 1 RCU for upto 4 KB of data, essentially doubling your read costs. DynamoDB provides you with the flexibility to use both consistency models on the same table.

You can evaluate your workload and application code to confirm if strongly consistent reads are used only where required.

Perform fewer transactions for read operations

DynamoDB allows you to group certain actions in an all-or-nothing manner, which means you have the ability to execute ACID transactions with DynamoDB. However, as is the case with relational databases, it is not necessary to follow this approach for every action.

A transactional read operation of up to 4 KB consumes 2 RCUs as opposed to the default 0.5 RCUs for reading the same amount of data in an eventually consistent manner. The costs are doubled in write operations which means, a transactional write of up to 1 KB equates to 2 WCUs.

To determine if all operations on your tables are transactions, CloudWatch metrics for the table can be filtered down to the transaction APIs. If transaction APIs are the only graphs available under the `SuccessfulRequestLatency` metrics for the table, this would confirm that every operation is a transaction for this table. Alternatively, if the overall capacity utilization trend matches the transaction API trend, consider revisiting the application design as it seems dominated by transactional APIs.

Perform fewer scans

The extensive use of `Scan` operations generally stems from the need to run analytical queries on the DynamoDB data. Running frequent `Scan` operations on large table can be inefficient and expensive.

A better alternative is to use the Export to S3 feature and choosing a point in time to export the table state to S3. AWS offers services like Athena which can then be used to run analytical queries on the data without consuming any capacity from the table.

The frequency for `Scan` operations can be determined using the `SampleCount` statistic under the `SuccessfulRequestLatency` metric for `Scan`. If `Scan` operations are indeed very frequent, the access patterns and data model should be re-evaluated.

Shorten attribute names

The total size of an item in DynamoDB is the sum of its attribute name lengths and values. Having long attribute names not only contributes towards storage costs, but it might also lead to higher RCU/WCU consumption. We recommend that you choose shorter attribute names rather than long ones. Having shorter attribute names can help limit the item size within the next 4KB/1KB boundary after which you would consume additional RCU/WCU to access data.

Enable Time to Live (TTL)

Time to Live (TTL) can identify items older than the expiry time that you have set on an item and remove them from the table. If your data grows over time and older data becomes irrelevant, enabling TTL on the table can help trim your data down and save on storage costs.

Another useful aspect of TTL is that the expired items occur on your DynamoDB streams, so rather than just removing the data from your data, it is possible to consume those items from the stream

and archive them to a lower cost storage tier. Additionally, deleting items through TTL comes at no additional cost — it does not consume capacity, and there's no overhead of designing a clean up application.

Replace global tables with cross-Region backups

Global tables allow you to maintain multiple active replica tables in different Regions — they can all accept write operations and replicate data across each other. It is easy to set up replicas and the synchronization is managed for you. The replicas converge to a consistent state using a last writer wins strategy.

If you are using Global tables purely as a part of failover or disaster recovery (DR) strategy, you can replace them with a cross-Region backup copy for relatively lenient recovery point objectives and recovery time objective requirements. If you do not require fast local access and the high availability of five nines, maintaining a global table replica might not be the best approach for failover.

As an alternative, consider using AWS Backup to manage DynamoDB backups. You can schedule regular backups and copy them across Regions to meet DR requirements in a more cost-effective approach compared to using Global tables.

Evaluate your DynamoDB streams usage

This section provides an overview of how to evaluate your DynamoDB Streams usage. There are certain usage patterns which are not optimal for DynamoDB, and they allow room for optimization from both a performance and cost perspective.

You have two native streaming integrations for streaming and event-driven use cases:

- Amazon DynamoDB Streams
- Amazon Kinesis Data Streams

This page will just focus on cost optimization strategies for these options. If you'd like to instead find out how to choose between the two options, see Streaming options for change data capture.

Topics

- Optimizing costs for DynamoDB Streams
- Optimizing costs for Kinesis Data Streams

- Cost optimization strategies for both types of Streams usage

Optimizing costs for DynamoDB Streams

As mentioned in the pricing page for DynamoDB Streams, regardless of the table's throughput capacity mode, DynamoDB charges on the number of read requests made towards the table's DynamoDB Stream. Read requests made towards a DynamoDB Stream are different from the read requests made towards a DynamoDB table.

Each read request in terms of the stream is in the form of a `GetRecords` API call that can return up to 1000 records or 1 MB worth of records in the response, whichever is reached first. None of the other DynamoDB Stream APIs are charged and DynamoDB Streams are not charged for being idle. In other words, if no read requests are made to a DynamoDB Stream, no charges will be incurred for having a DynamoDB Stream enabled on a table.

Here are a few consumer applications for DynamoDB Streams:

- AWS Lambda function(s)
- Amazon Kinesis Data Streams-based applications
- Customer consumer applications built using an AWS SDK

Read requests made by AWS Lambda-based consumers of DynamoDB Streams are free, whereas calls made by consumers of any other kind are charged. Every month, the first 2,500,000 read requests made by non-Lambda consumers are also free of cost. This applies to all read requests made to any DynamoDB Streams in an AWS Account for each AWS Region.

Monitoring your DynamoDB Streams usage

DynamoDB Streams charges on the billing console are grouped together for all DynamoDB Streams across the AWS Region in an AWS Account. Currently, tagging DynamoDB Streams is not supported, so cost allocation tags cannot be used to identify granular costs for DynamoDB Streams. The volume of `GetRecords` calls can be obtained at the DynamoDB Stream level to compute the charges per stream. The volume is represented by the DynamoDB Stream's CloudWatch metric `SuccessfulRequestLatency` and its `SampleCount` statistic. This metric will also include `GetRecords` calls made by global tables to perform on-going replication as well as calls made by AWS Lambda consumers, both of which are not charged. For information on other CloudWatch metrics published by DynamoDB Streams, see DynamoDB Metrics and dimensions.

Using AWS Lambda as the consumer

Evaluate if using AWS Lambda functions as the consumers for DynamoDB Streams is feasible because that can eliminate costs associated with reading from the DynamoDB Stream. On the other hand, DynamoDB Streams Kinesis Adapter or SDK based consumer applications will be charged on the number of `GetRecords` calls they make towards the DynamoDB Stream.

Lambda function invocations will be charged based on standard Lambda pricing, however no charges will be incurred by DynamoDB Streams. Lambda will poll shards in your DynamoDB Stream for records at a base rate of 4 times per second. When records are available, Lambda invokes your function and waits for the result. If processing succeeds, Lambda resumes polling until it receives more records.

Tuning DynamoDB Streams Kinesis Adapter-based consumer applications

Since read requests made by non-Lambda based consumers are charged for DynamoDB Streams, it is important to find a balance between the near real-time requirement and the number of times the consumer application must poll the DynamoDB Stream.

The frequency of polling DynamoDB Streams using a DynamoDB Streams Kinesis Adapter based application is determined by the configured `idleTimeBetweenReadsInMillis` value. This parameter determines the amount of time in milliseconds that the consumer should wait before processing a shard in case the previous `GetRecords` call made to the same shard did not return any records. By default, this value for this parameter is 1000 ms. If near real-time processing is not required, this parameter could be increased to have the consumer application make fewer `GetRecords` calls and optimize on DynamoDB Streams calls.

Optimizing costs for Kinesis Data Streams

When a Kinesis Data Stream is set as the destination to deliver change data capture events for a DynamoDB table, the Kinesis Data Stream might need separate sizing management which will affect the overall costs. DynamoDB charges in terms of Change Data capture Units (CDUs) where each unit is a made of up a 1 KB DynamoDB item size attempted by the DynamoDB service to the destination Kinesis Data Stream.

In addition to charges by the DynamoDB service, standard Kinesis Data Stream charges will be incurred. As mentioned in the pricing page, the service pricing differs based on the capacity mode - provisioned and on-demand, which are distinct from DynamoDB table capacity modes and are user-defined. At a high level, Kinesis Data Streams charges an hourly rate based on the capacity mode, as well as on data ingested into the stream by DynamoDB service. There might be additional

charges like data retrieval (for on-demand mode), extended data retention (beyond default 24 hours), and enhanced fan-out consumer retrievals depending on the user configuration for the Kinesis Data Stream.

Monitoring your Kinesis Data Streams usage

Kinesis Data Streams for DynamoDB publishes metrics from DynamoDB in addition to standard Kinesis Data Stream CloudWatch Metrics. It might be possible that a `Put` attempt by the DynamoDB service is throttled by the Kinesis service because of insufficient Kinesis Data Streams capacity, or by dependent components like a AWS KMS service that might be configured to encrypt the Kinesis Data Stream data at rest.

To learn more about CloudWatch metrics published by DynamoDB service for the Kinesis Data Stream, see Monitoring change data capture with Kinesis Data Streams. In order to avoid additional costs of service retries due to throttles, it is important to right size the Kinesis Data Stream in case of Provisioned Mode.

Choosing the right capacity mode for Kinesis Data Streams

Kinesis Data Streams are supported in two capacity modes – provisioned mode and on-demand mode.

- If the workload involving Kinesis Data Stream has predictable application traffic, traffic that is consistent or ramps gradually, or traffic that can be forecasted accurately, then Kinesis Data Streams' **provisioned mode** is suitable and will be more cost efficient
- If the workload is new, has unpredictable application traffic, or you prefer not to manage capacity, then Kinesis Data Streams' **on-demand mode** is suitable and will be more cost efficient

A best practice to optimize costs would be to evaluate if the DynamoDB table associated with the Kinesis Data Stream has a predictable traffic pattern that can leverage provisioned mode of Kinesis Data Streams. If the workload is new, you could use on-demand mode for the Kinesis Data Streams for a few initial weeks, review the CloudWatch metrics to understand traffic patterns, and then switch the same Stream to provisioned mode based on the nature of the workload. In the case of provisioned mode, estimation on number shards can be made by following shard management considerations for Kinesis Data Streams.

Evaluate your consumer applications using Kinesis Data Streams for DynamoDB

Since Kinesis Data Streams don't charge on the number of `GetRecords` calls like DynamoDB Streams, consumer applications could make as many number of calls as possible, provided the

frequency is under the throttling limits for `GetRecords`. In terms of on-demand mode for Kinesis Data Streams, data reads are charged on a per GB basis. For provisioned mode Kinesis Data Streams, reads are not charged if the data is less than 7 days old. In the case of Lambda functions as Kinesis Data Streams consumers, Lambda polls each shard in your Kinesis Stream for records at a base rate of once per second.

Cost optimization strategies for both types of Streams usage

Event filtering for AWS Lambda consumers

Lambda event filtering allows you to discard events based on a filter criteria from being available in the Lambda function invocation batch. This optimizes Lambda costs for processing or discarding unwanted stream records within the consumer function logic. To learn more about configuring event filtering and writing your filtering criteria, see Lambda event filtering.

Tuning AWS Lambda consumers

Costs could be further be optimized by tuning Lambda configuration parameters like increasing the `BatchSize` to process more per invocation, enabling `BisectBatchOnFunctionError` to prevent processing duplicates (which incurs additional costs), and setting `MaximumRetryAttempts` to not run into too many retries. By default, failed consumer Lambda invocations are retried infinitely until the record expires from the stream, which is around 24 hours for DynamoDB Streams and configurable from 24 hours to up to 1 year for Kinesis Data Streams. Additional Lambda configuration options available including the ones mentioned above for DynamoDB Stream consumers are in the AWS Lambda developer guide.

Evaluate your provisioned capacity for right-sized provisioning in your DynamoDB table

This section provides an overview of how to evaluate if you have right-sized provisioning on your DynamoDB tables. As your workload evolves, you should modify your operational procedures appropriately, especially when your DynamoDB table is configured in provisioned mode and you have the risk to over-provision or under-provision your tables.

The procedures described below require statistical information that should be captured from the DynamoDB tables that are supporting your production application. To understand your application behavior, you should define a period of time that is significant enough to capture the data seasonality from your application. For example, if your application shows weekly patterns, using a three week period should give you enough room for analysing application throughput needs.

If you don't know where to start, use at least one month's worth of data usage for the calculations below.

While evaluating capacity, DynamoDB tables can configure **Read Capacity Units (RCUs)** and **Write Capacity Units (WCU)** independently. If your tables have any Global Secondary Indexes (GSI) configured, you will need to specify the throughput that it will consume, which will be also independent from the RCUs and WCUs from the base table.

> **Note**
>
> Local Secondary Indexes (LSI) consume capacity from the base table.

Topics

- How to retrieve consumption metrics on your DynamoDB tables
- How to identify under-provisioned DynamoDB tables
- How to identify over-provisioned DynamoDB tables

How to retrieve consumption metrics on your DynamoDB tables

To evaluate the table and GSI capacity, monitor the following CloudWatch metrics and select the appropriate dimension to retrieve either table or GSI information:

Read Capacity Units	Write Capacity Units
`ConsumedReadCapacityUnits`	`ConsumedWriteCapacityUnits`
`ProvisionedReadCapacityUnits`	`ProvisionedWriteCapacityUnits`
`ReadThrottleEvents`	`WriteThrottleEvents`

You can do this either through the AWS CLI or the AWS Management Console.

AWS CLI

Before we retrieve the table consumption metrics, we'll need to start by capturing some historical data points using the CloudWatch API.

Start by creating two files: `write-calc.json` and `read-calc.json`. These files will represent the calculations for a table or GSI. You'll need to update some of the fields, as indicated in the table below, to match your environment.

Field Name	Definition	Example
`<table-name>`	The name of the table that you will be analysing	SampleTable
`<period>`	The period of time that you will be using to evaluate the utilization target, based in seconds	For a 1-hour period you should specify: 3600
`<start-time>`	The beginning of your evaluation interval, specified in ISO8601 format	2022-02-21T23:00:00
`<end-time>`	The end of your evaluatio n interval, specified in ISO8601 format	2022-02-22T06:00:00

The write calculations file will retrieve the number of WCU provisioned and consumed in the time period for the date range specified. It will also generate a utilization percentage that will be used for analysis. The full content of the `write-calc.json` file should look like this:

```
{
  "MetricDataQueries": [
    {
      "Id": "provisionedWCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ProvisionedWriteCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>"
            }
```

```
          ]
        },
        "Period": <period>,
        "Stat": "Average"
      },
      "Label": "Provisioned",
      "ReturnData": false
    },
    {
      "Id": "consumedWCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ConsumedWriteCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>""
            }
          ]
        },
        "Period": <period>,
        "Stat": "Sum"
      },
      "Label": "",
      "ReturnData": false
    },
    {
      "Id": "m1",
      "Expression": "consumedWCU/PERIOD(consumedWCU)",
      "Label": "Consumed WCUs",
      "ReturnData": false
    },
    {
      "Id": "utilizationPercentage",
      "Expression": "100*(m1/provisionedWCU)",
      "Label": "Utilization Percentage",
      "ReturnData": true
    }
  ],
  "StartTime": "<start-time>",
  "EndTime": "<ent-time>",
  "ScanBy": "TimestampDescending",
  "MaxDatapoints": 24
```

```
}
```

The read calculations file uses a similar file. This file will retrieve how many RCUs were provisioned and consumed during the time period for the date range specified. The contents of the `read-calc.json` file should look like this:

```
{
  "MetricDataQueries": [
    {
      "Id": "provisionedRCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ProvisionedReadCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>"
            }
          ]
        },
        "Period": <period>,
        "Stat": "Average"
      },
      "Label": "Provisioned",
      "ReturnData": false
    },
    {
      "Id": "consumedRCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ConsumedReadCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>"
            }
          ]
        },
        "Period": <period>,
        "Stat": "Sum"
      },
```

```
      "Label": "",
      "ReturnData": false
    },
    {
      "Id": "m1",
      "Expression": "consumedRCU/PERIOD(consumedRCU)",
      "Label": "Consumed RCUs",
      "ReturnData": false
    },
    {
      "Id": "utilizationPercentage",
      "Expression": "100*(m1/provisionedRCU)",
      "Label": "Utilization Percentage",
      "ReturnData": true
    }
  ],
  "StartTime": "<start-time>",
  "EndTime": "<end-time>",
  "ScanBy": "TimestampDescending",
  "MaxDatapoints": 24
}
```

One you've created the files, you can start retrieving utilization data.

1. To retreive the write utilization data, issue the following command:

   ```
   aws cloudwatch get-metric-data --cli-input-json file://write-calc.json
   ```

2. To retreive the read utilization data, issue the following command:

   ```
   aws cloudwatch get-metric-data --cli-input-json file://read-calc.json
   ```

The result for both queries will be a series of data points in JSON format that will be used for analysis. Your result will depend on the number of data points you specified, the period, and your own specific workload data. It could look something like this:

```
{
    "MetricDataResults": [
        {
            "Id": "utilizationPercentage",
            "Label": "Utilization Percentage",
```

```
            "Timestamps": [
                "2022-02-22T05:00:00+00:00",
                "2022-02-22T04:00:00+00:00",
                "2022-02-22T03:00:00+00:00",
                "2022-02-22T02:00:00+00:00",
                "2022-02-22T01:00:00+00:00",
                "2022-02-22T00:00:00+00:00",
                "2022-02-21T23:00:00+00:00"
            ],
            "Values": [
                91.55364583333333,
                55.066631944444445,
                2.6114930555555556,
                24.9496875,
                40.94725694444445,
                25.61819444444444,
                0.0
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

> **Note**
>
> If you specify a short period and a long time range, you might need to modify the `MaxDatapoints` which is by default set to 24 in the script. This represents one data point per hour and 24 per day.

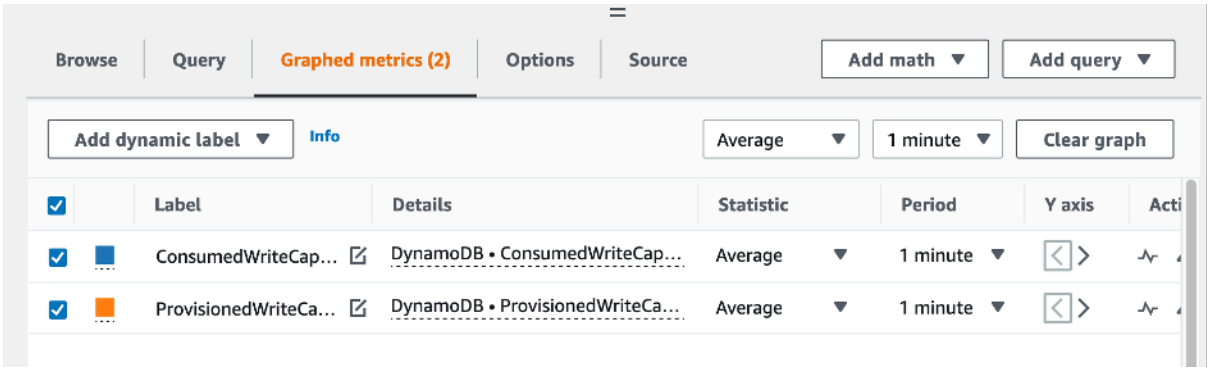
AWS Management Console

1. Log into the AWS Management Console and navigate to the CloudWatch service page. Select an appropriate AWS Region if necessary.
2. Locate the **Metrics** section on the left navigation bar and select **All metrics**.
3. This will open a dashboard with two panels. The top panel will show you the graphic, and the bottom panel will show the metrics you want to graph. Choose **DynamoDB**.
4. Choose **Table Metrics**. This will show you the tables in your current Region.

5. Use the Search box to search for your table name and choose the write operation metrics: `ConsumedWriteCapacityUnits` and `ProvisionedWriteCapacityUnits`

> **Note**
>
> This example talks about write operation metrics, but you can also use these steps to graph the read operation metrics.

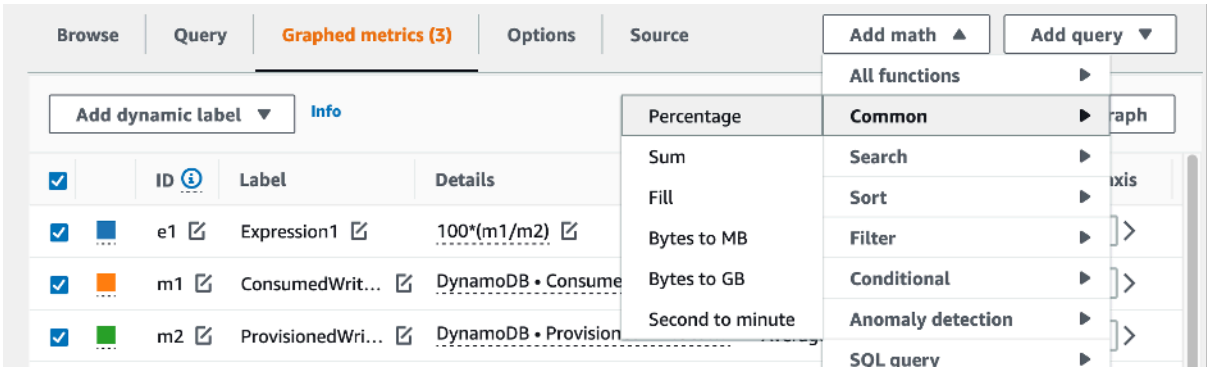
6. Choose the **Graphed metrics (2)** tab to modify the formulas. By default, CloudWatch selects the statistical function **Average** for the graphs.



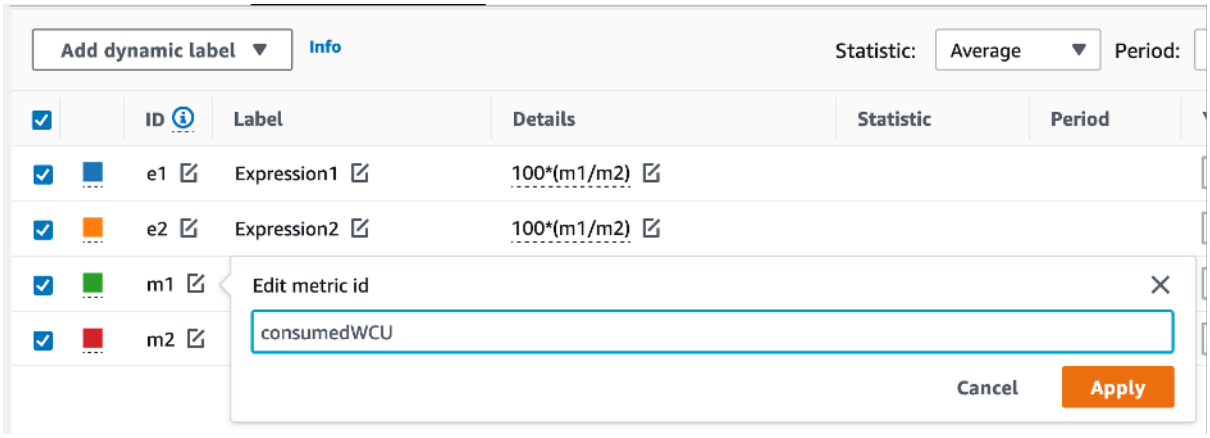
7. While having both graphed metrics selected (the checkbox on the left) select the menu **Add math**, followed by **Common**, and then select the **Percentage** function. Repeat the procedure twice.

   First time selecting the **Percentage** function:

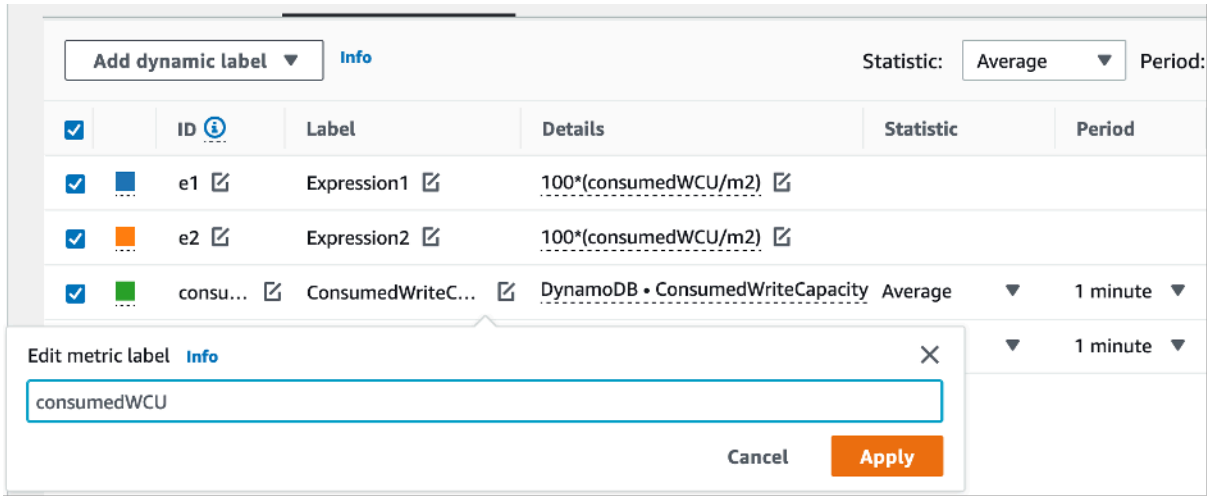
   Second time selecting the **Percentage** function:



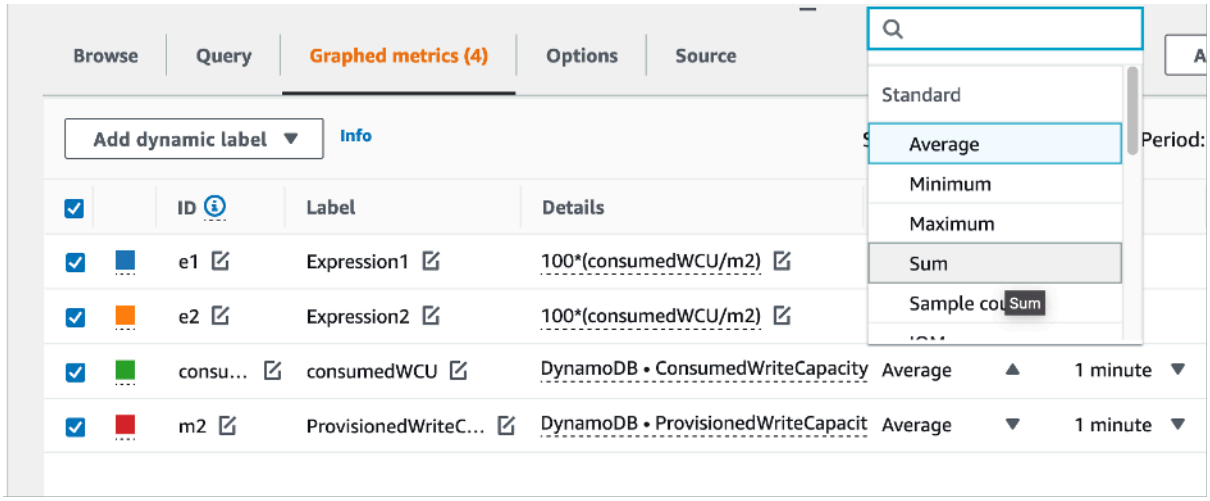
8. At this point you should have four metrics in the bottom menu. Let's work on the `ConsumedWriteCapacityUnits` calculation. To be consistent, you need to match the names used in the AWS CLI section. Choose the **m1 ID** and change this value to **consumedWCU**.

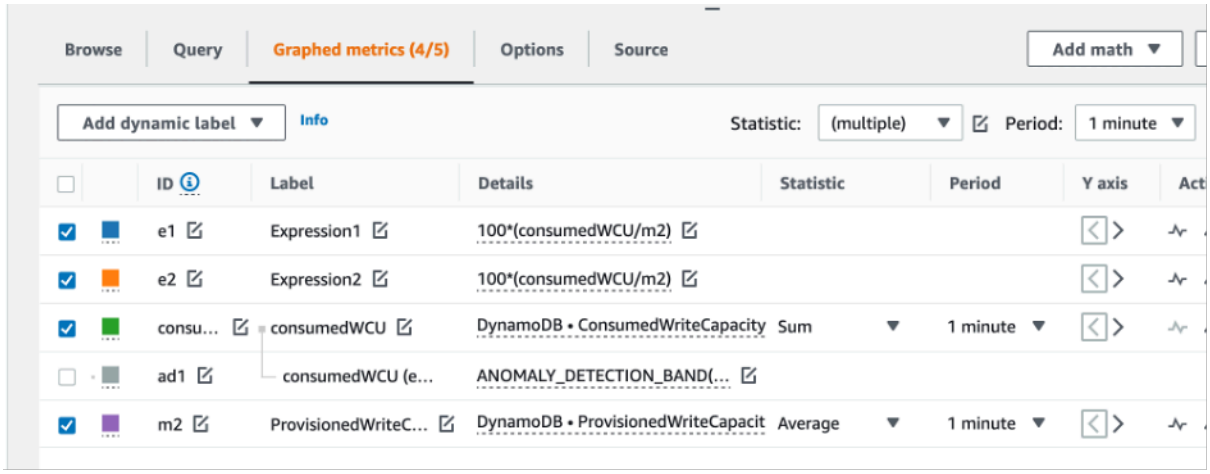


Rename the **ConsumedWriteCapacityUnit** label as **consumedWCU**.

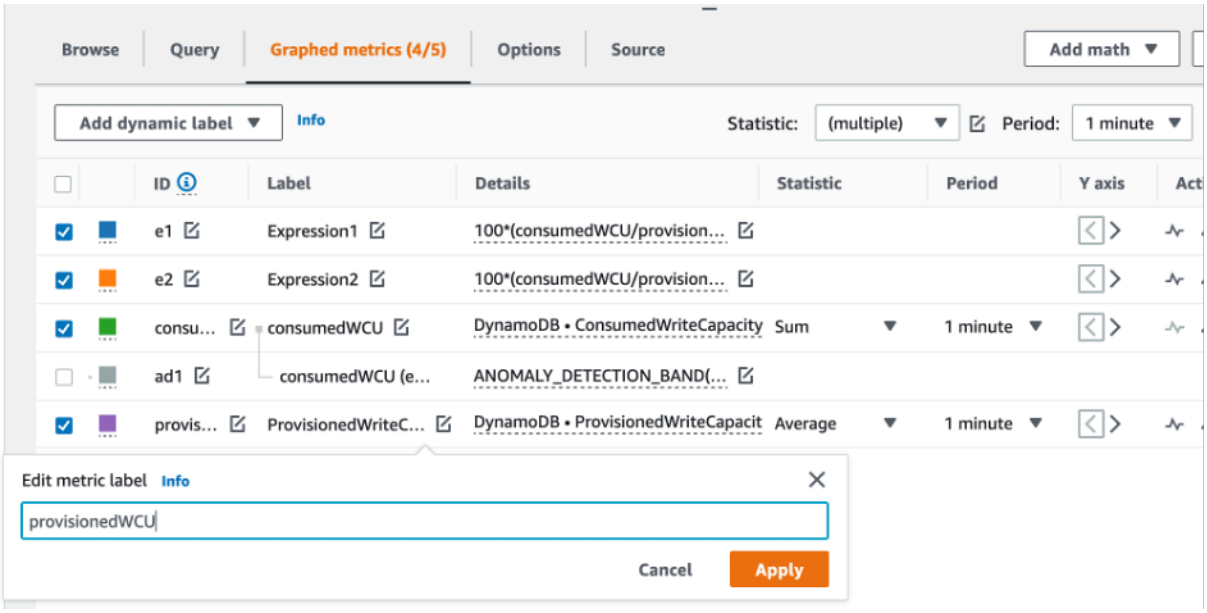


9. Change the statistic from **Average** to **Sum**. This action will automatically create another metric called **ANOMALY_DETECTION_BAND**. For the scope of this procedure, let's ignore it by removing the checkbox on the newly generated **ad1 metric**.





10. Repeat step 8 to rename the **m2 ID** to **provisionedWCU**. Leave the statistic set to **Average**.



11. Select the **Expression1** label and update the value to **m1** and the label to **Consumed WCUs**.

> **Note**
>
> Make sure you have only selected **m1** (checkbox on the left) and **provisionedWCU** to properly visualize the data. Update the formula by clicking in **Details** and changing the formula to **consumedWCU/PERIOD(consumedWCU)**. This step might also generate another **ANOMALY_DETECTION_BAND** metric, but for the scope of this procedure you can ignore it.
>
> >

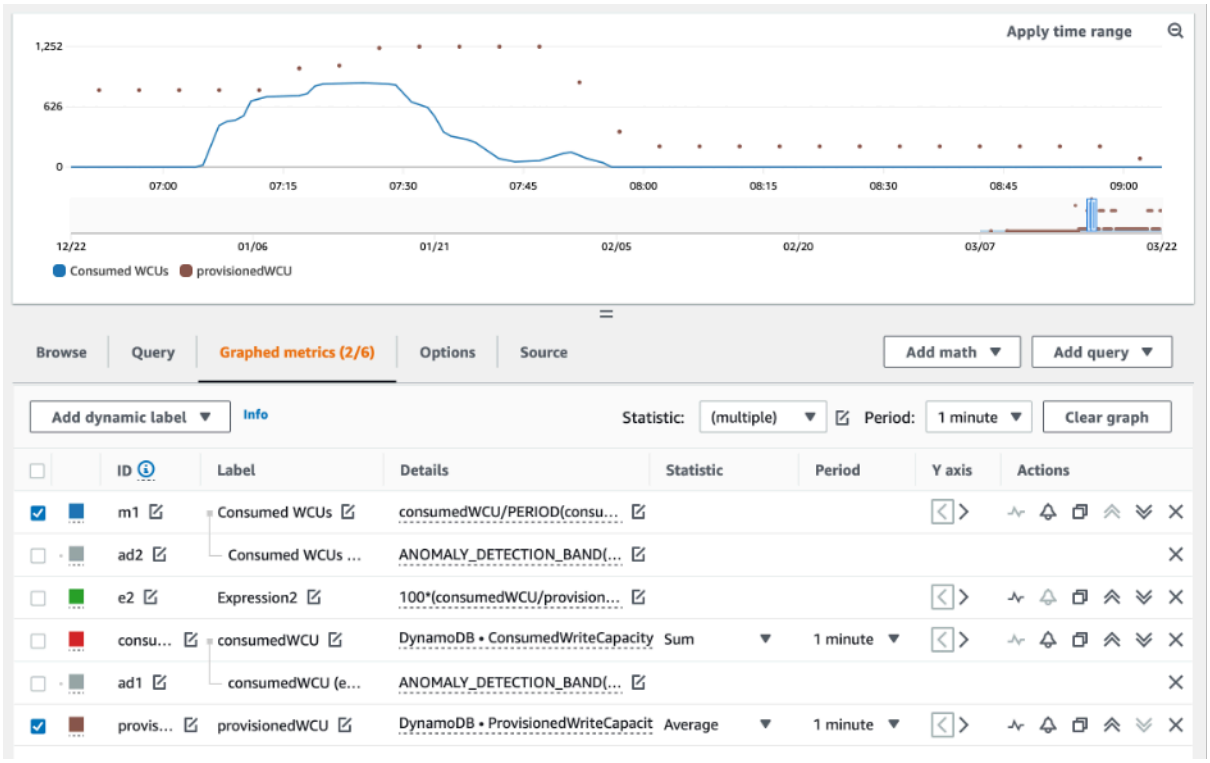
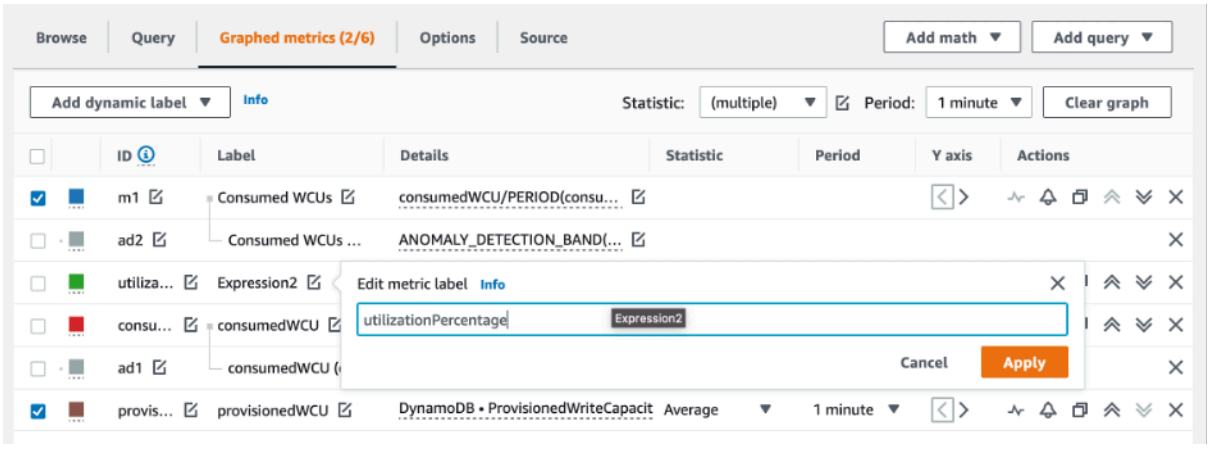
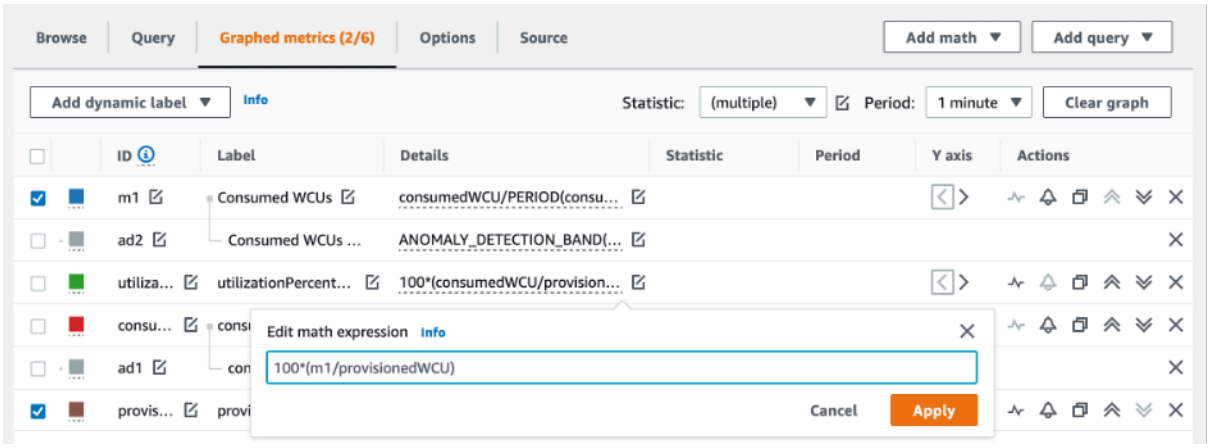
12. You should have now have two graphics: one that indicates your provisioned WCUs on the table and another that indicates the consumed WCUs. The shape of the graphic might be different from the one below, but you can use it as reference:



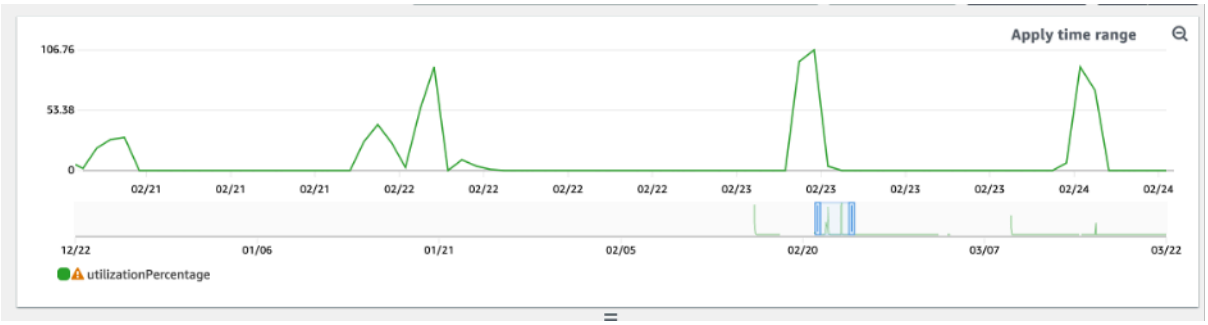
13. Update the percentage formula by selecting the Expression2 graphic (**e2**). Rename the labels and IDs to **utilizationPercentage**. Rename the formula to match **100*(m1/provisionedWCU)**.





14. Remove the checkbox from all the metrics but **utilizationPercentage** to visualize your utilization patterns. The default interval is set to 1 minute, but feel free to modify it as you need.

Here is view of a longer period of time as well as a bigger period of 1 hour. You can see there are some intervals where the utilization was higher than 100%, but this particular workload has longer intervals with zero utilization.



At this point, you might have different results from the pictures in this example. It all depends on the data from your workload. Intervals with more than 100% utilization are prone to throttling events. DynamoDB offers burst capacity, but as soon as the burst capacity is done anything above 100% will be throttled.

How to identify under-provisioned DynamoDB tables

For most workloads, a table is considered under-provisioned when it constantly consumes more than 80% of their provisioned capacity.

Burst capacity is a DynamoDB feature that allow customers to temporarily consume more RCUs/WCUs than originally provisioned (more than the per-second provisioned throughput that was defined in the table). The burst capacity was created to absorb sudden increases in traffic due to special events or usage spikes. This burst capacity doesn't last forever. As soon as the unused RCUs and WCUs are depleted, you will get throttled if you try to consume more capacity than provisioned. When your application traffic is getting close to the 80% utilization rate, your risk of throttling is significantly higher.

The 80% utilization rate rule varies from the seasonality of your data and your traffic growth. Consider the following scenarios:

- If your traffic has been **stable** at ~90% utilization rate for the last 12 months, your table has just the right capacity
- If your application traffic is **growing** at a rate of 8% monthly in less than 3 months, you will arrive at 100%
- If your application traffic is **growing** at a rate of 5% in a little more than 4 months, you will still arrive at 100%

The results from the queries above provide a picture of your utilization rate. Use them as a guide to further evaluate other metrics that can help you choose to increase your table capacity as required (for example: a monthly or weekly growth rate). Work with your operations team to define what is a good percentage for your workload and your tables.

There are special scenarios where the data is skewed when we analyse it on a daily or weekly basis. For example, with seasonal applications that have spikes in usage during working hours (but then drops to almost zero outside of working hours), you could benefit by scheduling auto scaling where you specify the hours of the day (and the days of the week) to increase the provisioned capacity and when to reduce it. Instead of aiming for higher capacity so you can cover the busy hours, you can also benefit from DynamoDB table auto scaling configurations if your seasonality is less pronounced.

> **Note**
>
> When you create a DynamoDB auto scaling configuration for your base table, remember to include another configuration for any GSI that is associated with the table.

How to identify over-provisioned DynamoDB tables

The query results obtained from the scripts above provide the data points required to perform some initial analysis. If your data set presents values lower than 20% utilization for several intervals, your table might be over-provisioned. To further define if you need to reduce the number of WCUs and RCUS, you should revisit the other readings in the intervals.

When your tables contain several low usage intervals, you can really benefit from using auto scaling policies, either by scheduling auto scaling or just configuring the default auto scaling policies for the table that are based on utilization.

If you have a workload with low utilization to high throttle ratio (**Max(ThrottleEvents)/ Min(ThrottleEvents)** in the interval), this could happen when you have a very spiky workload where traffic increases a lot during some days (or hours), but in general the traffic is consistently low. In these scenarios it might be beneficial to use scheduled auto scaling.

The AWS Well-Architected Framework helps cloud architects build secure, high-performing, resilient, and efficient infrastructure for a variety of applications and workloads. Built around six pillars—operational excellence, security, reliability, performance efficiency, cost optimization, and sustainability—AWS Well-Architected provides a consistent approach for customers and partners to evaluate architectures and implement scalable designs.

The AWS Well-Architected Lenses extend the guidance offered by AWS Well-Architected to specific industry and technology domains. The Amazon DynamoDB Well-Architected Lens focuses on DynamoDB workloads. It provides best practices, design principles and questions to assess and review a DynamoDB workload. Completing an Amazon DynamoDB Well-Architected Lens review will provide you with education and guidance around recommended design principles as it relates to each of the AWS Well-Architected pillars. This guidance is based on our experience working with customers across various industries, segments, sizes and geographies.

As a direct outcome of the Well-Architected Lens review, you will receive a summary of actionable recommendations to optimize and improve your DynamoDB workload.

Conducting the Amazon DynamoDB Well-Architected Lens review

The DynamoDB Well-Architected Lens review is usually performed by an AWS Solutions Architect together with the customer, but can also be performed by the customer as a self-service. While we recommend reviewing all six of the Well-Architected Pillars as part of the Amazon DynamoDB Well-Architected Lens, you can also decide to prioritize your focus on one or more pillars first.

Additional information and instructions for conducting an Amazon DynamoDB Well-Architected Lens review are available in this video and the DynamoDB Well-Architected Lens GitHub page.

The pillars of the Amazon DynamoDB Well-Architected Lens

The Amazon DynamoDB Well-Architected Lens is built around six pillars:

Performance efficiency pillar

The performance efficiency pillar includes the ability to use computing resources efficiently to meet system requirements, and to maintain that efficiency as demand changes and technologies evolve.

The primary DynamoDB design principles for this pillar revolve around modeling the data, choosing partition keys and sort keys, and defining secondary indexes based on the application access patterns. Additional considerations include choosing the optimal throughput mode for the workload, AWS SDK tuning and, when appropriate, using an optimal caching strategy. For more information about these design principles, refer to the deep dive video about the performance efficiency pillar of the DynamoDB Well-Architected Lens.

Cost optimization pillar

The cost optimization pillar focuses on avoiding unnecessary costs.

Key topics include understanding and controlling where money is being spent, selecting the most appropriate and right number of resource types, analyzing spend over time, designing your data models to optimize the cost for application-specific access patterns, and scaling to meet business needs without overspending.

The key cost optimization design principles for DynamoDB revolve around choosing the most appropriate capacity mode and table class for your tables and avoiding over-provisioning capacity by either using the on-demand capacity mode, or provisioned capacity mode with autoscaling. Additional considerations include efficient data modeling and querying to reduce the amount of

consumed capacity, reserving portions of the consumed capacity at discounted price, minimizing item size, identifying and removing unused resources and using TTL to automatically delete aged-out data at no cost. To learn more about these design principles, refer to the deep dive video about the cost optimization pillar of the DynamoDB Well-Architected Lens.

See Cost optimization for additional information on cost optimization best practices for DynamoDB.

Operational excellence pillar

The operational excellence pillar focuses on running and monitoring systems to deliver business value, and continually improving processes and procedures. Key topics include automating changes, responding to events, and defining standards to manage daily operations.

The main operational excellence design principles for DynamoDB include monitoring DynamoDB metrics through Amazon CloudWatch and AWS Config and automatically alert and remediate when predefined thresholds are breached, or non compliant rules are detected. Additional considerations are defining DynamoDB resources through infrastructure as code and leveraging tags for better organization, identification and cost accounting of your DynamoDB resources. To learn more about these design principles, refer to the deep dive video about the operational excellence pillar of the DynamoDB Well-Architected Lens.

Reliability pillar

The reliability pillar focuses on ensuring a workload performs its intended function correctly and consistently when it's expected to. A resilient workload quickly recovers from failures to meet business and customer demand. Key topics include distributed system design, recovery planning, and how to handle change.

The essential reliability design principles for DynamoDB revolve around choosing the backup strategy and retention based on your RPO and RTO requirements, and using DynamoDB global tables for multi-regional workloads or cross-region disaster recovery scenarios with low RTO. You should also implement retry logic with exponential backoff in your application by configuring these capabilities in the AWS SDK, and monitor DynamoDB metrics through Amazon CloudWatch to automatically alert and remediate when predefined thresholds are breached. For more information about these design principles, refer to the deep dive video about the reliability pillar of the DynamoDB Well-Architected Lens.

Security pillar

The security pillar focuses on protecting information and systems. Key topics include confidentiality and integrity of data, identifying and managing who can do what with privilege management, protecting systems, and establishing controls to detect security events.

The main security design principles for DynamoDB are encrypting data in transit with HTTPS, choosing the type of keys for data at rest encryption and defining the IAM roles and policies to authenticate, authorize and provide fine grain access to DynamoDB resources. Additional considerations include auditing DynamoDB control plane and data plane operations through AWS CloudTrail. For more information about these design principles, refer to the deep dive video about the security pillar of the DynamoDB Well-Architected Lens.

See Security for additional information on security for DynamoDB.

Sustainability pillar

The sustainability pillar focuses on minimizing the environmental impacts of running cloud workloads. Key topics include a shared responsibility model for sustainability, understanding impact, and maximizing utilization to minimize required resources and reduce downstream impacts.

The main sustainability design principles for DynamoDB include identifying and removing unused DynamoDB resources, and avoiding over-provisioning through the use of on-demand capacity mode or provisioned capacity mode with autoscaling. You can also reduce capacity consumption through efficient querying, and reduce the storage footprint by compressing data and deleting aged-out data through TTL. For more information about these design principles, refer to the deep dive video about the sustainability pillar of the DynamoDB Well-Architected Lens.

Best practices for designing and using partition keys effectively in DynamoDB

The primary key that uniquely identifies each item in an Amazon DynamoDB table can be simple (a partition key only) or composite (a partition key combined with a sort key).

You should design your application for uniform activity across all partition keys in the table and its secondary indexes. You can determine the access patterns that your application requires, and read and write units that each table and secondary index requires.

> **Note**
>
> Adaptive capacity applies to on-demand mode and provisioned capacity.

Every partition in a DynamoDB table is designed to deliver a maximum capacity of 3,000 read units per second and 1,000 write units per second. One read unit represents one strongly consistent read operation per second, or two eventually consistent read operations per second, for an item up to 4 KB in size. One write unit represents one write operation per second for an item up to 1 KB in size.

You must factor in the item size when evaluating the partition throughput limits for your table. For example, if the table has an item size of 20 KB, a single consistent read operation will consume 5 read units. This means you can concurrently drive 600 consistent read operations per second on that single item before reaching the partition limits. The total throughput across all partitions in the table can be constrained by the provisioned throughput in provisioned mode, or by the table level throughput limit in on-demand mode. See Service Quotas for more information.

- Designing partition keys to distribute your workload in DynamoDB
- Using write sharding to distribute workloads evenly in your DynamoDB table
- Distributing write activity efficiently during data upload in DynamoDB

Designing partition keys to distribute your workload in DynamoDB

The partition key portion of a table's primary key determines the logical partitions in which a table's data is stored. This in turn affects the underlying physical partitions. A partition key design that doesn't distribute I/O requests effectively can create "hot" partitions that result in throttling and use your provisioned I/O capacity inefficiently.

The optimal usage of a table's provisioned throughput depends not only on the workload patterns of individual items, but also on the partition key design. This doesn't mean that you must access all partition key values to achieve an efficient throughput level, or even that the percentage of accessed partition key values must be high. It does mean that the more distinct partition key values that your workload accesses, the more those requests will be spread across the partitioned space. In general, you'll use your provisioned throughput more efficiently as the ratio of partition key values accessed to the total number of partition key values increases.

The following is a comparison of the provisioned throughput efficiency of some common partition key schemas.

Partition key value	Uniformity
User ID, where the application has many users.	Good
Status code, where there are only a few possible status codes.	Bad
Item creation date, rounded to the nearest time period (for example, day, hour, or minute).	Bad
Device ID, where each device accesses data at relatively similar intervals.	Good
Device ID, where even if there are many devices being tracked, one is by far more popular than all the others.	Bad

If a single table has only a small number of partition key values, consider distributing your write operations across more distinct partition key values. In other words, structure the primary key elements to avoid one "hot" (heavily requested) partition key value that slows overall performance.

For example, consider a table with a composite primary key. The partition key represents the item's creation date, rounded to the nearest day. The sort key is an item identifier. On a given day, say `2014-07-09`, **all** of the new items are written to that single partition key value (and corresponding physical partition).

If the table fits entirely into a single partition (considering growth of your data over time), and if your application's read and write throughput requirements don't exceed the read and write capabilities of a single partition, your application won't encounter any unexpected throttling as a result of partitioning.

To use NoSQL Workbench for DynamoDB to help visualize your partition key design, see Building data models with NoSQL Workbench.

Using write sharding to distribute workloads evenly in your DynamoDB table

One way to better distribute writes across a partition key space in Amazon DynamoDB is to expand the space. You can do this in several different ways. You can add a random number to the partition key values to distribute the items among partitions. Or you can use a number that is calculated based on something that you're querying on.

Sharding using random suffixes

One strategy for distributing loads more evenly across a partition key space is to add a random number to the end of the partition key values. Then you randomize the writes across the larger space.

For example, for a partition key that represents today's date, you might choose a random number between 1 and 200 and concatenate it as a suffix to the date. This yields partition key values like 2014-07-09.1, 2014-07-09.2, and so on, through 2014-07-09.200. Because you are randomizing the partition key, the writes to the table on each day are spread evenly across multiple partitions. This results in better parallelism and higher overall throughput.

However, to read all the items for a given day, you would have to query the items for all the suffixes and then merge the results. For example, you would first issue a Query request for the partition key value 2014-07-09.1. Then issue another Query for 2014-07-09.2, and so on, through 2014-07-09.200. Finally, your application would have to merge the results from all those Query requests.

Sharding using calculated suffixes

A randomizing strategy can greatly improve write throughput. But it's difficult to read a specific item because you don't know which suffix value was used when writing the item. To make it easier to read individual items, you can use a different strategy. Instead of using a random number to distribute the items among partitions, use a number that you can calculate based upon something that you want to query on.

Consider the previous example, in which a table uses today's date in the partition key. Now suppose that each item has an accessible OrderId attribute, and that you most often need to find items by order ID in addition to date. Before your application writes the item to the table, it could calculate a hash suffix based on the order ID and append it to the partition key date. The calculation might

generate a number between 1 and 200 that is fairly evenly distributed, similar to what the random strategy produces.

A simple calculation would likely suffice, such as the product of the UTF-8 code point values for the characters in the order ID, modulo 200, + 1. The partition key value would then be the date concatenated with the calculation result.

With this strategy, the writes are spread evenly across the partition key values, and thus across the physical partitions. You can easily perform a `GetItem` operation for a particular item and date because you can calculate the partition key value for a specific `OrderId` value.

To read all the items for a given day, you still must `Query` each of the `2014-07-09.N` keys (where `N` is 1–200), and your application then has to merge all the results. The benefit is that you avoid having a single "hot" partition key value taking all of the workload.

> **Note**
>
> For a more efficient strategy specifically designed to handle high-volume time series data, see Time series data.

Distributing write activity efficiently during data upload in DynamoDB

Typically, when you load data from other data sources, Amazon DynamoDB partitions your table data on multiple servers. You get better performance if you upload data to all the allocated servers simultaneously.

For example, suppose that you want to upload user messages to a DynamoDB table that uses a composite primary key with `UserID` as the partition key and `MessageID` as the sort key.

When you upload the data, one approach you can take is to upload all message items for each user, one user after another:

UserID	MessageID
U1	1
U1	2

UserID	MessageID
U1	...
U1	... up to 100
U2	1
U2	2
U2	...
U2	... up to 200

The problem in this case is that you are not distributing your write requests to DynamoDB across your partition key values. You are taking one partition key value at a time and uploading all of its items before going to the next partition key value and doing the same.

Behind the scenes, DynamoDB is partitioning the data in your table across multiple servers. To fully use all the throughput capacity that is provisioned for the table, you must distribute your workload across your partition key values.

By directing an uneven amount of upload work toward items that all have the same partition key value, you are not fully using all the resources that DynamoDB has provisioned for your table.

You can distribute your upload work by using the sort key to load one item from each partition key value, then another item from each partition key value, and so on:

UserID	MessageID
U1	1
U2	1
U3	1
...	...
U1	2

UserID	MessageID
U2	2
U3	2
...	...

Every upload in this sequence uses a different partition key value, keeping more DynamoDB servers busy simultaneously and improving your throughput performance.

Best practices for using sort keys to organize data in DynamoDB

In an Amazon DynamoDB table, the primary key that uniquely identifies each item in the table can be composed of a partition key and a sort key.

Well-designed sort keys have two key benefits:

- They gather related information together in one place where it can be queried efficiently. Careful design of the sort key lets you retrieve commonly needed groups of related items using range queries with operators such as `begins_with`, `between`, >, <, and so on.
- Composite sort keys let you define hierarchical (one-to-many) relationships in your data that you can query at any level of the hierarchy.

  For example, in a table listing geographical locations, you might structure the sort key as follows.

  ```
  [country]#[region]#[state]#[county]#[city]#[neighborhood]
  ```

  This would let you make efficient range queries for a list of locations at any one of these levels of aggregation, from `country`, to a `neighborhood`, and everything in between.

Using sort keys for version control

Many applications need to maintain a history of item-level revisions for audit or compliance purposes and to be able to retrieve the most recent version easily. There is an effective design pattern that accomplishes this using sort key prefixes:

- For each new item, create two copies of the item: One copy should have a version-number prefix of zero (such as `v0_`) at the beginning of the sort key, and one should have a version-number prefix of one (such as `v1_`).
- Every time the item is updated, use the next higher version-prefix in the sort key of the updated version, and copy the updated contents into the item with version-prefix zero. This means that the latest version of any item can be located easily using the zero prefix.

For example, a parts manufacturer might use a schema like the one illustrated below.

Primary Key		Data-Item Attributes...				
Partition Key *Equipment_ID*	Sort Key *(varies)*	Attribute 1	Attribute 2	Attribute 3	Attribute 4	...
Equipment_1	Details	Name: Biphasic Cardiometer *(equipment name)*	Factory_ID: S14_Tukwilla *(factory where manufactured)*	Line_ID R_7 *(assembly-line ID)*		
	v0_Audit	Auditor: Padma *(name of the auditor)*	Latest: 3 *(most recent audit version)*	Time: 2018-04-15T11:00 *(audit date and time)*	Result Passed *(audit result)*	...etc.
	v1_Audit	Auditor: Rick *(name of the auditor)*	Time: 2018-03-14T11:00 *(audit date and time)*	Result Open *(audit result)*	Report: 0943922EKG14 *(detailed problem report in S3)*	...etc.
	v2_Audit	Auditor: George *(name of the auditor)*	Time: 2018-03-18T11:00 *(audit date and time)*	Result Open *(audit result)*	Report: 0943923EKG15 *(detailed problem report in S3)*	...etc.
	v3_Audit	Auditor: Padma *(name of the auditor)*	Time: 2018-04-15T11:00 *(audit date and time)*	Result Passed *(audit result)*	Report: x792 *(pass confirmation report)*	...etc.

The `Equipment_1` item goes through a sequence of audits by various auditors. The results of each new audit are captured in a new item in the table, starting with version number one, and then incrementing the number for each successive revision.

When each new revision is added, the application layer replaces the contents of the zero-version item (having sort key equal to `v0_Audit`) with the contents of the new revision.

Whenever the application needs to retrieve for the most recent audit status, it can query for the sort key prefix of `v0_`.

If the application needs to retrieve the entire revision history, it can query all the items under the item's partition key and filter out the `v0_` item.

This design also works for audits across multiple parts of a piece of equipment, if you include the individual part-IDs in the sort key after the sort key prefix.

Best practices for using secondary indexes in DynamoDB

Secondary indexes are often essential to support the query patterns that your application requires. At the same time, overusing secondary indexes or using them inefficiently can add cost and reduce performance unnecessarily.

General guidelines for secondary indexes in DynamoDB

Amazon DynamoDB supports two types of secondary indexes:

- **Global secondary index (GSI)—** An index with a partition key and a sort key that can be different from those on the base table. A global secondary index is considered "global" because queries on the index can span all of the data in the base table, across all partitions. A global secondary index has no size limitations and has its own provisioned throughput settings for read and write activity that are separate from those of the table.
- **Local secondary index (LSI)—**An index that has the same partition key as the base table, but a different sort key. A local secondary index is "local" in the sense that every partition of a local secondary index is scoped to a base table partition that has the same partition key value. As a result, the total size of indexed items for any one partition key value can't exceed 10 GB. Also, a local secondary index shares provisioned throughput settings for read and write activity with the table it is indexing.

Each table in DynamoDB can have up to 20 global secondary indexes (default quota) and 5 local secondary indexes.

Global secondary indexes are often more useful than local secondary indexes. Determining which type of index to use will also depend on your application's requirements. For a comparison of global secondary indexes and local secondary indexes, and more information on how to choose between them, see the section called “Working with secondary indexes”.

The following are some general principles and design patterns to keep in mind when creating indexes in DynamoDB:

Topics

- Use indexes efficiently
- Choose projections carefully
- Optimize frequent queries to avoid fetches
- Be aware of item-collection size limits when creating local secondary indexes

Use indexes efficiently

Keep the number of indexes to a minimum. Don't create secondary indexes on attributes that you don't query often. Indexes that are seldom used contribute to increased storage and I/O costs without improving application performance.

Choose projections carefully

Because secondary indexes consume storage and provisioned throughput, you should keep the size of the index as small as possible. Also, the smaller the index, the greater the performance advantage compared to querying the full table. If your queries usually return only a small subset of attributes, and the total size of those attributes is much smaller than the whole item, project only the attributes that you regularly request.

If you expect a lot of write activity on a table compared to reads, follow these best practices:

- Consider projecting fewer attributes to minimize the size of items written to the index. However, this only applies if the size of projected attributes would otherwise be larger than a single write capacity unit (1 KB). For example, if the size of an index entry is only 200 bytes, DynamoDB rounds this up to 1 KB. In other words, as long as the index items are small, you can project more attributes at no extra cost.
- Avoid projecting attributes that you know will rarely be needed in queries. Every time you update an attribute that is projected in an index, you incur the extra cost of updating the index as well. You can still retrieve non-projected attributes in a `Query` at a higher provisioned throughput cost, but the query cost might be significantly lower than the cost of updating the index frequently.
- Specify `ALL` only if you want your queries to return the entire table item sorted by a different sort key. Projecting all attributes eliminates the need for table fetches, but in most cases, it doubles your costs for storage and write activity.

Balance the need to keep your indexes as small as possible against the need to keep fetches to a minimum, as explained in the next section.

Optimize frequent queries to avoid fetches

To get the fastest queries with the lowest possible latency, project all the attributes that you expect those queries to return. In particular, if you query a local secondary index for attributes that are not

projected, DynamoDB automatically fetches those attributes from the table, which requires reading the entire item from the table. This introduces latency and additional I/O operations that you can avoid.

Keep in mind that "occasional" queries can often turn into "essential" queries. If there are attributes that you don't intend to project because you anticipate querying them only occasionally, consider whether circumstances might change and you might regret not projecting those attributes after all.

For more information about table fetches, see Provisioned throughput considerations for Local Secondary Indexes.

Be aware of item-collection size limits when creating local secondary indexes

An *item collection* is all the items in a table and its local secondary indexes that have the same partition key. No item collection can exceed 10 GB, so it's possible to run out of space for a particular partition key value.

When you add or update a table item, DynamoDB updates all local secondary indexes that are affected. If the indexed attributes are defined in the table, the local secondary indexes grow too.

When you create a local secondary index, think about how much data will be written to it, and how many of those data items will have the same partition key value. If you expect that the sum of table and index items for a particular partition key value might exceed 10 GB, consider whether you should avoid creating the index.

If you can't avoid creating the local secondary index, you must anticipate the item collection size limit and take action before you exceed it. As a best practice, you should utilize the `ReturnItemCollectionMetrics` parameter when writing items to monitor and alert on item collection sizes that approach the 10GB size limit. Exceeding the maximum item collection size will result in failed write attempts. You can mitigate the item collection size issues by monitoring and alerting on item collection sizes before they impact your application.

> **Note**
>
> After a local secondary index is created, you cannot delete it.

For strategies on working within the limit and taking corrective action, see Item collection size limit.

Take advantage of sparse indexes

For any item in a table, DynamoDB writes a corresponding index entry **only if the index key attributes are present in the item**. For a global secondary index, this means the index partition key must be defined on the item, and if the index also has a sort key, that attribute must be present too. If either key attribute is missing from an item, that item does not appear in the index. An index where only a subset of items from the base table appear is called a *sparse* index.

Sparse indexes are useful for queries over a small subsection of a table. For example, suppose that you have a table where you store all your customer orders, with the following key attributes:

- Partition key: `CustomerId`
- Sort key: `OrderId`

To track open orders, you can insert an attribute named `isOpen` in order items that have not already shipped. Then when the order ships, you can delete the attribute. If you then create an index on `CustomerId` (partition key) and `isOpen` (sort key), only those orders with `isOpen` defined appear in it. When you have thousands of orders of which only a small number are open, it's faster and less expensive to query that index for open orders than to scan the entire table.

Instead of using a type of attribute like `isOpen`, you could use an attribute with a value that results in a useful sort order in the index. For example, you could use an `OrderOpenDate` attribute set to the date on which each order was placed, and then delete it after the order is fulfilled. That way, when you query the sparse index, the items are returned sorted by the date on which each order was placed.

Examples of sparse indexes in DynamoDB

Global secondary indexes are sparse by default. When you create a global secondary index, you specify a partition key and optionally a sort key. Only items in the base table that contain the required key attributes appear in the index. If an item is missing the index partition key—or the sort key, when one is defined—that item is excluded from the index.

By designing a global secondary index to be sparse, you can provision it with lower write throughput than that of the base table, while still achieving excellent performance.

For example, a gaming application might track all scores of every user, but generally only needs to query a few high scores. The following design handles this scenario efficiently:

Table

Primary Key		Data Attributes...		
Partition Key	*Sort Key*			
Player_ID	Game_ID	Attribute 1	Attribute 2	Attribute 3
Rick	Game_1	Score: 36,750 *(game score)*	Date: 2017-11-14 *(date of game)*	
	Game_2	Score: 69,450 *(game score)*	Date: 2017-12-31 *(date of game)*	
	Game_3	Score: 135,900 *(game score)*	Date: 2018-01-19 *(date of game)*	Award: Champ *(type of award)*
Padma	Game_4	Score: 25,350 *(game score)*	Date: 2018-01-27 *(date of game)*	
	Game_5	Score: 69,450 *(game score)*	Date: 2028-01-19 *(date of game)*	
	Game_6	Score: 147,300 *(game score)*	Date: 2018-02-02 *(date of game)*	Award: Champ *(type of award)*
	Game_7	Score: 169,100 *(game score)*	Date: 2018-03-10 *(date of game)*	Award: Champ *(type of award)*

Here, Rick has played three games and achieved `Champ` status in one of them. Padma has played four games and achieved `Champ` status in two of them. Notice that the `Award` attribute is present only in items where the user achieved an award. The associated global secondary index looks like the following:

GSI

Primary Key	Projected Attributes...			
Partition Key				
Award	Player_ID	Game_ID	Score	Date
Champ	Rick	Game_3	135,900	2018-01-19
	Padma	Game_6	147,300	2018-02-02
	Padma	Game_7	169,100	2018-03-10

The global secondary index contains only the high scores that are frequently queried, which are a small subset of the items in the base table.

Using Global Secondary Indexes for materialized aggregation queries in DynamoDB

Maintaining near real-time aggregations and key metrics on top of rapidly changing data is becoming increasingly valuable to businesses for making rapid decisions. For example, a music

library might want to showcase its most downloaded songs in near-real time, or an e-commerce platform might need to display trending products by category.

Because DynamoDB doesn't natively support aggregation operations like `SUM` or `COUNT` across items, computing these values at read time would require scanning large numbers of items—which might be slow and expensive. Instead, you can *pre-compute* aggregations as data changes and store the results as regular items in your table. This pattern is called *materialized aggregation*.

Topics

- Example scenario and access patterns
- Why pre-compute aggregations
- Table design
- Aggregation pipeline with Streams and AWS Lambda
- Sparse GSI design
- Querying the GSI
- Considerations

Example scenario and access patterns

Consider a music library application with the following requirements:

- The application records individual song downloads at high volume (thousands per second).
- Users need to see the most downloaded songs for a given month with single-digit millisecond latency.
- The application also needs to support queries like "top 10 songs this month" and "all songs downloaded in a given month."

Computing download counts at read time by scanning all download records might be expensive at this scale. Instead, you can maintain a running count that updates as each download occurs, and store it in a way that supports efficient querying.

Why pre-compute aggregations

There are several approaches to computing aggregations. The following table compares common alternatives and explains why materialized aggregation in DynamoDB is often the best fit for this type of use case.

Approach	Tradeoffs	When to use
Scan and count at read time	Requires reading all download records for every query. Latency grows with data volume and consumes significant read capacity.	Only suitable for very small datasets where latency isn't a concern.
External aggregation store (for example, Amazon ElastiCache)	Adds operational complexity with a separate service to manage. Requires synchronization logic between DynamoDB and the cache.	When you need sub-millisecond reads or complex aggregation logic that goes beyond simple counts.
Application-level aggregation on write	Couples the aggregation logic to the write path. If the application fails after recording the download but before updating the count, the aggregation becomes inconsistent.	When you need synchronous, strongly consistent aggregation and can tolerate added write latency.
Materialized aggregation with Streams and Lambda	Decouples aggregation from the write path. Aggregation is eventually consistent (typically seconds behind). Adds Lambda invocation costs.	**When you need near real-time aggregations with low read latency and can tolerate eventual consistency.** This is the approach described on this page.

The materialized aggregation approach keeps the write path simple (just record the download), offloads the aggregation to an asynchronous process, and stores the result in DynamoDB where it can be queried with single-digit millisecond latency.

Table design

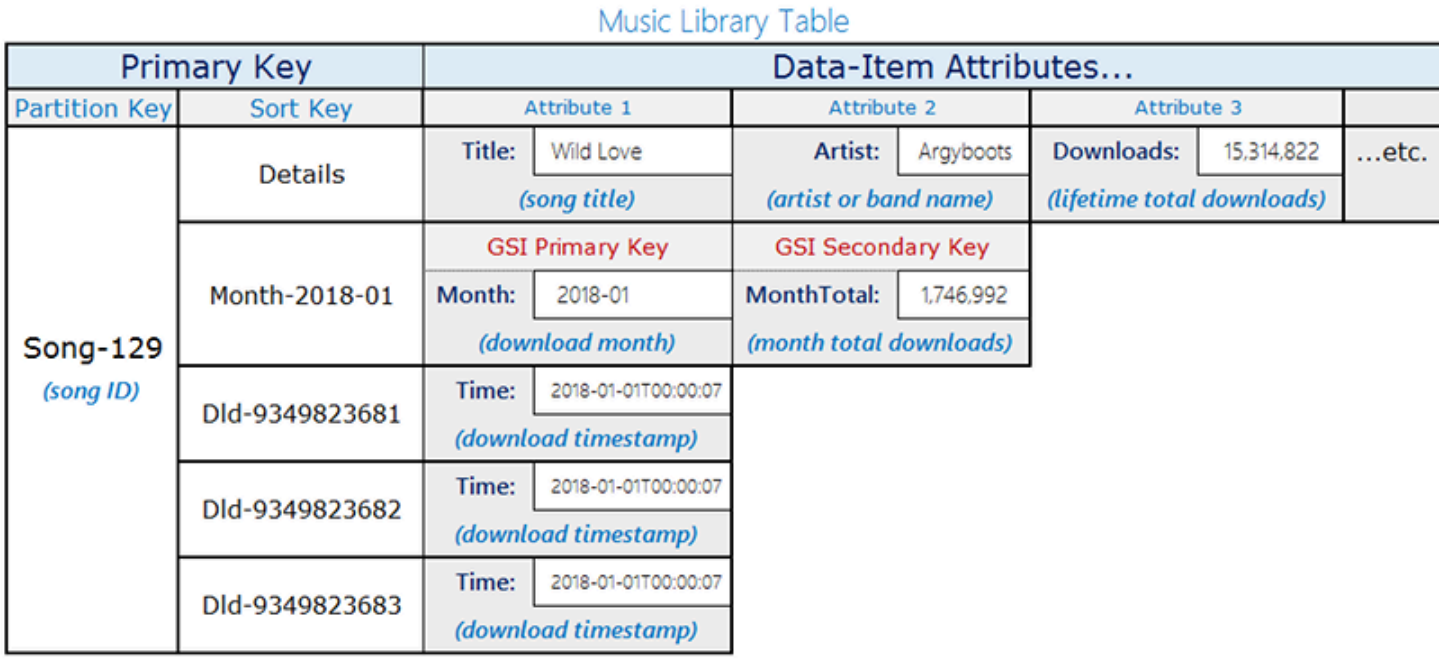
This design uses a single table with two item types that share the same partition key (`songID`) but use different sort key patterns to distinguish between them:

- **Download records** – Individual download events. The sort key is the `DownloadID` (a unique identifier for each download).

- **Monthly aggregation items** – Pre-computed download counts per song per month. The sort key is the month in `YYYY-MM` format (for example, `2018-01`). These items also contain a `DownloadCount` attribute with the running total.

Only the monthly aggregation items contain the `Month` attribute. This distinction is important for the sparse GSI design described later.

The following diagram shows the table layout with both item types:



Item type	Partition key (songID)	Sort key	Additional attributes
Download record	`song1`	`download-abc123`	`UserID`, `Timestamp`
Monthly aggregation	`song1`	`2018-01`	`Month=2018-01`, `DownloadCount =1,746,992`

Aggregation pipeline with Streams and AWS Lambda

The aggregation pipeline works as follows:

1. When a song is downloaded, the application writes a new item to the table with `Partition-Key=songID` and `Sort-Key=DownloadID`.
2. DynamoDB Streams captures this write as a stream record.
3. A Lambda function, attached to the stream, processes the new record. It identifies the `songID` and the current month, then updates the corresponding monthly aggregation item by incrementing the `DownloadCount` attribute.
4. The updated aggregation item is then available for querying through the sparse GSI.

The Lambda function uses an `UpdateItem` call with an `ADD` expression to atomically increment the download count. This avoids read-modify-write race conditions:

```
import boto3

dynamodb = boto3.resource('dynamodb')
table = dynamodb.Table('MusicLibrary')

def handler(event, context):
    for record in event['Records']:
        if record['eventName'] == 'INSERT':
            new_image = record['dynamodb']['NewImage']
            song_id = new_image['songID']['S']
            # Derive the month from the download timestamp
            timestamp = new_image['Timestamp']['S']
            month = timestamp[:7]  # Extract YYYY-MM

            table.update_item(
                Key={
                    'songID': song_id,
                    'SK': month
                },
                UpdateExpression='ADD DownloadCount :inc SET #m = :month',
                ExpressionAttributeNames={
                    '#m': 'Month'
                },
                ExpressionAttributeValues={
                    ':inc': 1,
                    ':month': month
                }
            )
```

Note

If a Lambda execution fails after writing the updated aggregation value, the stream record might be retried. Because the ADD operation increments the count each time it runs, a retry would increment the count more than once for the same download, leaving you with an *approximate* value. For most analytics and leaderboard use cases, this small margin of error is acceptable. If you need exact counts, consider adding idempotency logic—for example, by using a condition expression that checks whether the specific `DownloadID` has already been processed.

Sparse GSI design

To efficiently query the aggregated results, create a global secondary index with the following key schema:

- **GSI partition key:** `Month` (String)
- **GSI sort key:** `DownloadCount` (Number)

This GSI is *sparse* because only the monthly aggregation items contain the `Month` attribute. The individual download records don't have this attribute, so they are automatically excluded from the index. This means the GSI contains only the pre-computed aggregation items—a small fraction of the total items in the table.

A sparse GSI provides two key benefits:

- **Lower cost** – Because only aggregation items are replicated to the index, you consume far less write capacity and storage compared to an index that includes every item in the table.
- **Faster queries** – The index contains only the data you need to query, so reads are efficient and return results with single-digit millisecond latency.

For more information about how sparse indexes work, see Take advantage of sparse indexes.

Querying the GSI

With the sparse GSI in place, you can efficiently answer several types of queries:

Get the most downloaded song for a given month:

```
aws dynamodb query \
    --table-name "MusicLibrary" \
    --index-name "MonthDownloadsIndex" \
    --key-condition-expression "#m = :month" \
    --expression-attribute-names '{"#m": "Month"}' \
    --expression-attribute-values '{":month": {"S": "2018-01"}}' \
    --scan-index-forward false \
    --limit 1
```

Setting `ScanIndexForward` to `false` sorts results by `DownloadCount` in descending order, and `Limit=1` returns only the top song.

Get the top 10 songs for a given month:

```
aws dynamodb query \
    --table-name "MusicLibrary" \
    --index-name "MonthDownloadsIndex" \
    --key-condition-expression "#m = :month" \
    --expression-attribute-names '{"#m": "Month"}' \
    --expression-attribute-values '{":month": {"S": "2018-01"}}' \
    --scan-index-forward false \
    --limit 10
```

Get all songs downloaded in a given month (sorted by download count):

```
aws dynamodb query \
    --table-name "MusicLibrary" \
    --index-name "MonthDownloadsIndex" \
    --key-condition-expression "#m = :month" \
    --expression-attribute-names '{"#m": "Month"}' \
    --expression-attribute-values '{":month": {"S": "2018-01"}}' \
    --scan-index-forward false
```

Considerations

Keep the following in mind when implementing this pattern:

- **Eventual consistency** – The aggregation values are updated asynchronously through DynamoDB Streams and Lambda. There is typically a delay of a few seconds between a download being recorded and the aggregation being updated. This means the GSI reflects near real-time data, not real-time data.

- **Lambda concurrency** – If your table has a high write volume, multiple Lambda invocations might attempt to update the same aggregation item concurrently. The atomic ADD operation handles this safely, but you should monitor Lambda concurrency and throttling metrics to make sure your function can keep up with the stream.
- **GSI write capacity** – Because the sparse GSI only contains aggregation items, it requires significantly less write capacity than the base table. However, you should still provision enough capacity (or use on-demand mode) to handle the rate of aggregation updates.
- **Approximate counts** – As noted earlier, Lambda retries can cause counts to be slightly over-counted. For use cases that require exact counts, implement idempotency checks in the Lambda function.

Overloading Global Secondary Indexes in DynamoDB

Although Amazon DynamoDB has a default quota of 20 global secondary indexes per table, in practice, you can index across far more than 20 data fields. As opposed to a table in a relational database management system (RDBMS), in which the schema is uniform, a table in DynamoDB can hold many different kinds of data items at one time. In addition, the same attribute in different items can contain entirely different kinds of information.

Consider the following example of a DynamoDB table layout that saves a variety of different kinds of data.

Primary Key		Data-Item Attributes...		
Partition Key	Sort Key	Attribute 1	Attribute 2	...
HR-974 *(employee ID)*	Employee_Name	Data: Murphy, John *(employee name)*	Start: 2008-11-08 *(start date)*	...etc.
	YYYY-Q1	Data: $5,477 *(order totals in USD)*	Name: Murphy, John *(employee name)*	
	HR_confidential	Data: 2008-11-08 *(hire date)*	Name: Murphy, John *(employee name)*	...etc.
	Warehouse_01	Data: Murphy, John *(employee name)*		
	v0_Job_title	Data: Operator-1 *(job title)*	Start: 2008-11-08 *(start date)*	...etc.
	v1_Job_title	Data: Operator-2 *(job title)*	Start: 2016-11-04 *(start date)*	...etc.
	v2_Job_title	Data: Supervisor-1 *(job title)*	Start: 2017-11-01 *(start date)*	...etc.

The `Data` attribute, which is common to all the items, has different content depending on its parent item. If you create a global secondary index for the table that uses the table's sort key as its partition key and the `Data` attribute as its sort key, you can make a variety of different queries using that single global secondary index. These queries might include the following:

- Look up an employee by name in the global secondary index, using `Employee_Name` as the partition key value and the employee's name (for example `Murphy, John`) as the sort key value.
- Use the global secondary index to find all employees working in a particular warehouse by searching on a warehouse ID (such as `Warehouse_01`).
- Get a list of recent hires, querying the global secondary index on `HR_confidential` as a partition key value and using a range of dates in the sort key value.

Using Global Secondary Index write sharding for selective table queries in DynamoDB

When you need to query recent data within a specific time window, DynamoDB's requirement of providing a partition key for most read operations can present a challenge. To address this scenario, you can implement an effective query pattern using a combination of write sharding and a Global Secondary Index (GSI).

This approach allows you to efficiently retrieve and analyze time-sensitive data without performing full table scans, which can be resource-intensive and costly. By strategically designing your table structure and indexing, you can create a flexible solution that supports time-based data retrieval while maintaining optimal performance.

Topics

- Pattern design
- Sharding strategy
- Querying the sharded GSI
- Parallel query execution considerations
- Code example

Pattern design

When working with DynamoDB, you can overcome time-based data retrieval challenges by implementing a sophisticated pattern that combines write sharding and Global Secondary Indexes to enable flexible, efficient querying across recent data windows.

Structure of the table

- Partition Key (PK): "Username"

Structure of the GSI

- GSI Partition Key (PK_GSI): "ShardNumber#"
- GSI Sort Key (SK_GSI): ISO 8601 timestamp (e.g., "2030-04-01T12:00:00Z")

[TABLE] - TimeBounded Metadata Actions

PK	SK_GSI	Address	PK_GSI
Trenton69	2023-12-05T06:40:31.312Z	117 Hudson Divide	ShardNumber#0
Scot_Langworth-Prosacco	2024-10-09T14:44:45.819Z	84021 Herzog Skyway	ShardNumber#6
Juliet.Morissette	2025-03-28T07:20:56.538Z	4871 N Broadway	ShardNumber#4
Kay.Von71	2024-11-23T16:19:26.763Z	14554 Odell Throughway	ShardNumber#2
Kiarra43	2023-11-15T16:21:57.078Z	8471 London Road	ShardNumber#1
Marcella91	2024-12-17T09:02:31.623Z	10271 Nick Crescent	ShardNumber#6
Bernard.Lemke36	2025-09-09T00:18:34.482Z	5438 Douglas Groves	ShardNumber#2
Daisha83	2024-01-24T06:38:08.482Z	8786 Armstrong Radial	ShardNumber#3
Marcos_Schmitt58	2024-04-06T17:38:58.551Z	510 S Center Street	ShardNumber#3
Jeremie_VonRueden-Mills	2025-04-06T04:24:23.701Z	157 Koch Drives	ShardNumber#1
Verna28	2025-10-10T18:42:21.059Z	70040 Baylee Trafficway	ShardNumber#1
Trycia.Doyle	2024-01-10T17:00:08.360Z	9511 Tillman Extensions	ShardNumber#2

Sharding strategy

Assuming you decide to use 10 shards, your shard numbers could range from 0 to 9. When logging an activity, you would calculate the shard number (for example, by using a hash function on the user ID and then taking the modulus of the number of shards) and prepend it to the GSI partition key. This method distributes the entries across different shards, mitigating the risk of hot partitions.

Querying the sharded GSI

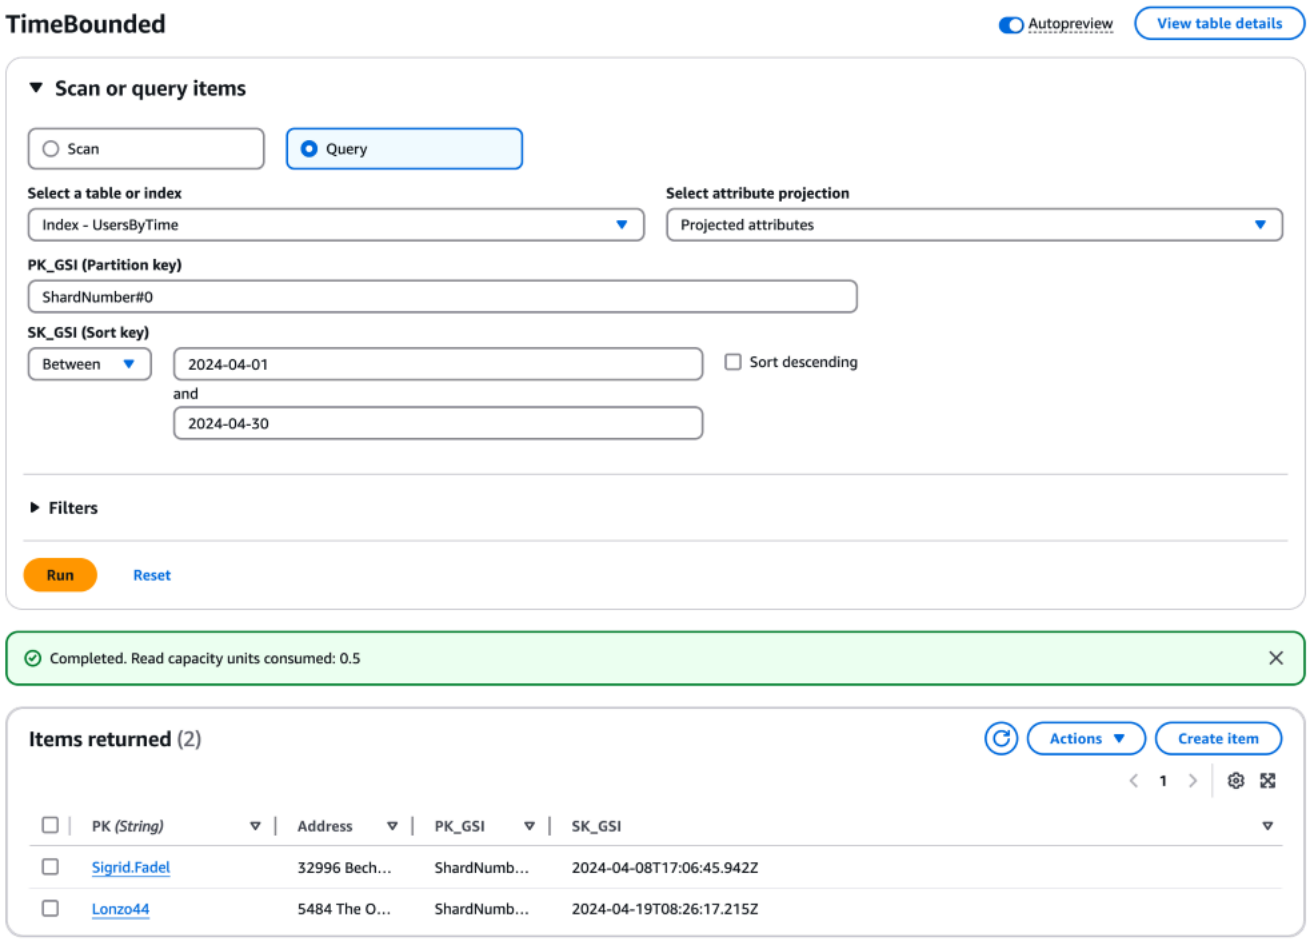
Querying across all shards for items within a particular time range in a DynamoDB table, where data is sharded across multiple partition keys, requires a different approach than querying a single partition. Since DynamoDB queries are limited to a single partition key at a time, you can't directly query across multiple shards with a single query operation. However, you can achieve the desired result through application-level logic by performing multiple queries, each targeting a specific shard, and then aggregating the results. The procedure below explains how to do this.

To query and aggregate shards

1. Identify the range of shard numbers used in your sharding strategy. For instance, if you have 10 shards, your shard numbers would range from 0-9.

2. For each shard, construct and execute a query to fetch items within the desired time range. These queries can be executed in parallel to improve efficiency. Use the partition key with the shard number and the sort key with your time range for these queries. Here's an example query for a single shard:

```
aws dynamodb query \
    --table-name "YourTableName" \
    --index-name "YourIndexName" \
    --key-condition-expression "PK_GSI = :pk_val AND SK_GSI BETWEEN :start_date
 AND :end_date" \
    --expression-attribute-values '{
        ":pk_val": {"S": "ShardNumber#0"},
        ":start_date": {"S": "2024-04-01"},
        ":end_date": {"S": "2024-04-30"}
    }'
```



You would replicate this query for each shard, adjusting the partition key accordingly (e.g., "ShardNumber#1", "ShardNumber#2", ..., "ShardNumber#9").

3. Aggregate the results from each query after all queries are complete. Perform this aggregation in your application code, combining the results into a single dataset that represents the items from all shards within your specified time range.

Parallel query execution considerations

Each query consumes read capacity from your table or index. If you're using provisioned throughput, make sure that your table is provisioned with enough capacity to handle the burst of parallel queries. If you're using on-demand capacity, be mindful of the potential cost implications.

Code example

To execute parallel queries across shards in DynamoDB using Python, you can use the boto3 library, which is the Amazon Web Services SDK for Python. This example assumes you have boto3 installed and configured with appropriate AWS credentials.

The following Python code demonstrates how to perform parallel queries across multiple shards for a given time range. It uses concurrent futures to execute queries in parallel, reducing the overall execution time compared to sequential execution.

```
import boto3
from concurrent.futures import ThreadPoolExecutor, as_completed

# Initialize a DynamoDB client
dynamodb = boto3.client('dynamodb')

# Define your table name and the total number of shards
table_name = 'YourTableName'
total_shards = 10  # Example: 10 shards numbered 0 to 9
time_start = "2030-03-15T09:00:00Z"
time_end = "2030-03-15T10:00:00Z"

def query_shard(shard_number):
    """
    Query items in a specific shard for the given time range.
    """
    response = dynamodb.query(
```

```
        TableName=table_name,
        IndexName='YourGSIName',  # Replace with your GSI name
        KeyConditionExpression="PK_GSI = :pk_val AND SK_GSI BETWEEN :date_start
 AND :date_end",
        ExpressionAttributeValues={
            ":pk_val": {"S": f"ShardNumber#{shard_number}"},
            ":date_start": {"S": time_start},
            ":date_end": {"S": time_end},
        }
    )
    return response['Items']

# Use ThreadPoolExecutor to query across shards in parallel
with ThreadPoolExecutor(max_workers=total_shards) as executor:
    # Submit a future for each shard query
    futures = {executor.submit(query_shard, shard_number): shard_number for
 shard_number in range(total_shards)}

    # Collect and aggregate results from all shards
    all_items = []
    for future in as_completed(futures):
        shard_number = futures[future]
        try:
            shard_items = future.result()
            all_items.extend(shard_items)
            print(f"Shard {shard_number} returned {len(shard_items)} items")
        except Exception as exc:
            print(f"Shard {shard_number} generated an exception: {exc}")

# Process the aggregated results (e.g., sorting, filtering) as needed
# For example, simply printing the count of all retrieved items
print(f"Total items retrieved from all shards: {len(all_items)}")
```

Before running this code, make sure to replace `YourTableName` and `YourGSIName` with the actual table and GSI names from your DynamoDB setup. Also, adjust `total_shards`, `time_start`, and `time_end` variables according to your specific requirements.

This script queries each shard for items within the specified time range and aggregates the results.

Using Global Secondary Indexes to create an eventually consistent replica in DynamoDB

You can use a global secondary index to create an eventually consistent replica of a table. Creating a replica can allow you to do the following:

- **Set different provisioned read capacity for different readers.** For example, suppose that you have two applications: One application handles high-priority queries and needs the highest levels of read performance, whereas the other handles low-priority queries that can tolerate throttling of read activity.

  If both of these applications read from the same table, a heavy read load from the low-priority application could consume all the available read capacity for the table. This would throttle the high-priority application's read activity.

  Instead, you can create a replica through a global secondary index whose read capacity you can set separate from that of the table itself. You can then have your low-priority app query the replica instead of the table.
- **Eliminate reads from a table entirely.** For example, you might have an application that captures a high volume of clickstream activity from a website, and you don't want to risk having reads interfere with that. You can isolate this table and prevent reads by other applications (see Using IAM policy conditions for fine-grained access control), while letting other applications read a replica created using a global secondary index.

To create a replica, set up a global secondary index that has the same key schema as the parent table, with some or all of the non-key attributes projected into it. In applications, you can direct some or all read activity to this global secondary index rather than to the parent table. You can then adjust the provisioned read capacity of the global secondary index to handle those reads without changing the parent table's provisioned read capacity.

There is always a short propagation delay between a write to the parent table and the time when the written data appears in the index. In other words, your applications should take into account that the global secondary index replica is only *eventually consistent* with the parent table.

You can create multiple global secondary index replicas to support different read patterns. When you create the replicas, project only the attributes that each read pattern actually requires. An application can then consume less provisioned read capacity to obtain only the data it needs rather

than having to read the item from the parent table. This optimization can result in significant cost savings over time.

Best practices for storing large items and attributes in DynamoDB

Amazon DynamoDB limits the size of each item that you store in a table to 400 KB (see Item size). If your application needs to store more data in an item than the DynamoDB size limit permits, you can try compressing one or more large attributes or breaking the item into multiple items (efficiently indexed by sort keys). You can also store the item as an object in Amazon Simple Storage Service (Amazon S3) and store the Amazon S3 object identifier in your DynamoDB item.

As a best practice, you should utilize the `ReturnConsumedCapacity` parameter when writing items to monitor and alert on items sizes that approach the 400 KB maximum item size. Exceeding the maximum item size will result in failed write attempts. DynamoDB will return a ValidationException error. Monitoring and alerting on item sizes will enable you to mitigate the items size issues before they impact your application.

Compressing large attribute values

Compressing large attribute values can let them fit within item limits in DynamoDB and reduce your storage costs. Compression algorithms such as GZIP or LZO produce binary output that you can then store in a `Binary` attribute type within the item.

As an example, consider a table that stores messages written by forum users. Such messages often contain long strings of text, which are candidates for compression. While compression can reduce item sizes, the downside is that the compressed attribute values are not useful for filtering.

For sample code that demonstrates how to compress such messages in DynamoDB, see the following:

- Example: Handling binary type attributes using the AWS SDK for Java document API
- Example: Handling binary type attributes using the AWS SDK for .NET low-level API

Vertical partitioning

An alternative solution to dealing with large items is to break them down into smaller chunks of data and associating all relevant items by the partition key value. You can then use a sort key string

to identify the associated information stored alongside it. By doing this, and having multiple items grouped by the same partition key value, you are creating an *item collection*.

For more information on this approach, see:

- Use vertical partitioning to scale data efficiently in Amazon DynamoDB
- Implement vertical partitioning in Amazon DynamoDB using AWS Glue

Storing large attribute values in Amazon S3

As mentioned previously, you can also use Amazon S3 to store large attribute values that cannot fit in a DynamoDB item. You can store them as an object in Amazon S3 and then store the object identifier in your DynamoDB item.

You can also use the object metadata support in Amazon S3 to provide a link back to the parent item in DynamoDB. Store the primary key value of the item as Amazon S3 metadata of the object in Amazon S3. Doing this often helps with maintenance of the Amazon S3 objects.

For example, consider the `ProductCatalog` table. Items in this table store information about item price, description, book authors, and dimensions for other products. If you wanted to store an image of each product that was too large to fit in an item, you could store the images in Amazon S3 instead of in DynamoDB.

When implementing this strategy, keep the following in mind:

- DynamoDB doesn't support transactions that cross Amazon S3 and DynamoDB. Therefore, your application must deal with any failures, which could include cleaning up orphaned Amazon S3 objects.
- Amazon S3 limits the length of object identifiers. So you must organize your data in a way that doesn't generate excessively long object identifiers or violate other Amazon S3 constraints.

For more information about how to use Amazon S3, see the Amazon Simple Storage Service User Guide.

Best practices for handling time series data in DynamoDB

General design principles in Amazon DynamoDB recommend that you keep the number of tables you use to a minimum. For most applications, a single table is all you need. However, for time series data, you can often best handle it by using one table per application per period.

Design pattern for time series data

Consider a typical time series scenario, where you want to track a high volume of events. Your write access pattern is that all the events being recorded have today's date. Your read access pattern might be to read today's events most frequently, yesterday's events much less frequently, and then older events very little at all. One way to handle this is by building the current date and time into the primary key.

The following design pattern often handles this kind of scenario effectively:

- Create one table per period, provisioned with the required read and write capacity and the required indexes.
- Before the end of each period, prebuild the table for the next period. Just as the current period ends, direct event traffic to the new table. You can assign names to these tables that specify the periods they have recorded.
- As soon as a table is no longer being written to, reduce its provisioned write capacity to a lower value (for example, 1 WCU), and provision whatever read capacity is appropriate. Reduce the provisioned read capacity of earlier tables as they age. You might choose to archive or delete the tables whose contents are rarely or never needed.

The idea is to allocate the required resources for the current period that will experience the highest volume of traffic and scale down provisioning for older tables that are not used actively, therefore saving costs. Depending on your business needs, you might consider write sharding to distribute traffic evenly to the logical partition key. For more information, see Using write sharding to distribute workloads evenly in your DynamoDB table.

Optimize storage costs with the Standard-IA table class

DynamoDB offers two table classes: DynamoDB Standard and DynamoDB Standard-Infrequent Access (DynamoDB Standard-IA). The Standard-IA table class lowers your storage costs while increasing the cost of read and write throughput. It's a good fit when storage is the dominant portion of a table's cost and the table is accessed infrequently.

This trade-off maps naturally onto the time series pattern. The current period's table receives most of the read and write traffic, so keep it on the DynamoDB Standard table class, where throughput is less expensive. As a table ages out of active use, it is written to rarely (or not at all) and read infrequently, while you continue to retain its data. For these older tables, storage typically becomes the largest cost, so switching them to the Standard-IA table class can lower your overall cost.

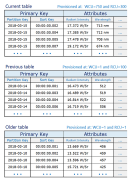
Consider the following when you apply table classes to time series tables:

- Keep the current (active) period on the DynamoDB Standard table class. The higher throughput cost of Standard-IA would outweigh its storage savings for a table that serves a high volume of reads and writes.
- Switch a period's table to Standard-IA after it is no longer actively written to and is accessed infrequently, but you still need to retain its data (for example, for compliance or occasional historical queries).
- You can set the table class when you create a table or change it later. Evaluate each table's storage-to-throughput cost ratio before switching, and monitor costs after the change.

For more information about table classes and how to choose between them, see DynamoDB table classes and Evaluate your DynamoDB table class selection.

Time series table examples

The following is a time series data example in which the current table is provisioned at a higher read/write capacity and the older tables are scaled down because they are accessed infrequently.



Best practices for managing many-to-many relationships in DynamoDB tables

Adjacency lists are a design pattern that is useful for modeling many-to-many relationships in Amazon DynamoDB. More generally, they provide a way to represent graph data (nodes and edges) in DynamoDB.

Adjacency list design pattern

When different entities of an application have a many-to-many relationship between them, the relationship can be modeled as an adjacency list. In this pattern, all top-level entities (synonymous to nodes in the graph model) are represented using the partition key. Any relationships with other entities (edges in a graph) are represented as an item within the partition by setting the value of the sort key to the target entity ID (target node).

The advantages of this pattern include minimal data duplication and simplified query patterns to find all entities (nodes) related to a target entity (having an edge to a target node).

A real-world example where this pattern has been useful is an invoicing system where invoices contain multiple bills. One bill can belong in multiple invoices. The partition key in this example is either an `InvoiceID` or a `BillID`. `BillID` partitions have all attributes specific to bills. `InvoiceID` partitions have an item storing invoice-specific attributes, and an item for each `BillID` that rolls up to the invoice.

The schema looks like the following.

Table	Primary Key		Data Attributes...	
	Partition Key	*Sort Key (and GSI PK)*		
	`Invoice-92551`	**Inv_ID:** Invoice-92551 *(invoice ID)*	**Dated:** 2018-02-07 *(date created)*	More attributes of this invoice...
		Bill_ID: Bill-4224663 *(bill ID)*	**Dated:** 2017-12-03 *(date created)*	Attributes of this bill *in this invoice*..
		Bill_ID: Bill-4224687 *(bill ID)*	**Dated:** 2018-01-09 *(date created)*	Attributes of this bill *in this invoice*..
	`Invoice-92552`	**Inv_ID:** Invoice-92552 *(invoice ID)*	**Dated:** 2018-03-04 *(date created)*	More attributes of this invoice...
		Bill_ID: Bill-4224687 *(bill ID)*	**Dated:** 2018-01-09 *(date created)*	Attributes of this bill *in this invoice*..
	`Bill-4224663`	**Bill_ID:** Bill-4224663 *(bill ID)*	**Dated:** 2017-12-03 *(date created)*	More attributes of this bill...
	`Bill-4224687`	**Bill_ID:** Bill-4224687 *(bill ID)*	**Dated:** 2018-01-09 *(date created)*	More attributes of this bill...

Using the preceding schema, you can see that all bills for an invoice can be queried using the primary key on the table. To look up all invoices that contain a part of a bill, create a global secondary index on the table's sort key.

The projections for the global secondary index look like the following.

GSI	Primary Key *Partition Key*	Projected Attributes...	
	Bill-4224663	Bill_ID: Bill-4224663 *(table primary key)*	Attributes of this bill...
		Inv_ID: Invoice-92551 *(table primary key)*	Attributes of this bill *in this invoice*..
	Bill-4224687	Bill_ID: Bill-4224687 *(table primary key)*	Attributes of this bill...
		Inv_ID: Invoice-92551 *(table primary key)*	Attributes of this bill *in this invoice*..
		Inv_ID: Invoice-92552 *(table primary key)*	Attributes of this bill *in this invoice*..
	Invoice-92551	Inv_ID: Invoice-92551 *(table primary key)*	Attributes of this invoice...
	Invoice-92552	Inv_ID: Invoice-92552 *(table primary key)*	Attributes of this invoice...

Materialized graph pattern

Many applications need to understand rankings across peers, relationships between entities, and neighbor entity state. If your application uses these types of graph style workflows, consider the following schema design pattern.

As a real-world example, consider a social networking application. In this application, people have relationships with other people, possess skills, live in places, and have associated dates (such as birthdates). Each person is a *node* in the graph. The connections between people, such as friendships, are *edges*. The associations between people and their attributes (skills, places, dates) are also edges.

With the materialized graph pattern, you can store both nodes and edges in a single DynamoDB table and efficiently traverse relationships. The following diagrams show how to model this social networking graph. The first diagram shows the primary table structure. The subsequent diagrams show the global secondary index projections.

TABLE	Primary Key		Attributes		
	PK (NodeId)	SK (TypeTarget, GSI 2 SK)	Data	GSI PK	Graph Projections
	1	DATE|2|BIRTH	1980-12-19	Hash(Person.Data)

The table uses the following key structure:

- **Partition key** – The entity ID (for example, `Person-1`, `Person-2`). Each partition contains one node item and multiple edge items.
- **Sort key** – For node items, the entity's own ID. For edge items, a composite of the edge type and target (for example, `Friend-Person-2` or `Skill-DynamoDB`).

Edge items contain a `Target` and a `Type` attribute. These form the composite key "TypeTarget" that identifies items in the primary table and in the second global secondary index. For example, "Person-1 is friends with Person-2" produces `Type=Friend`, `Target=Person-2`, and `TypeTarget=Friend-Person-2`.

The first global secondary index is built on the `Data` attribute. This attribute uses global secondary index overloading to index several attribute types within the same index:

- `Dates` – birthdates, join dates (for example, `1971-12-21`)
- `Names` – display names (for example, `Ana Carolina Silva`)

- `Places` – locations (for example, `Seattle`)
- `Skills` – competencies (for example, `DynamoDB`)

You can use this single global secondary index to query for all people born on a specific date, all people in a location, or all people with a specific skill.

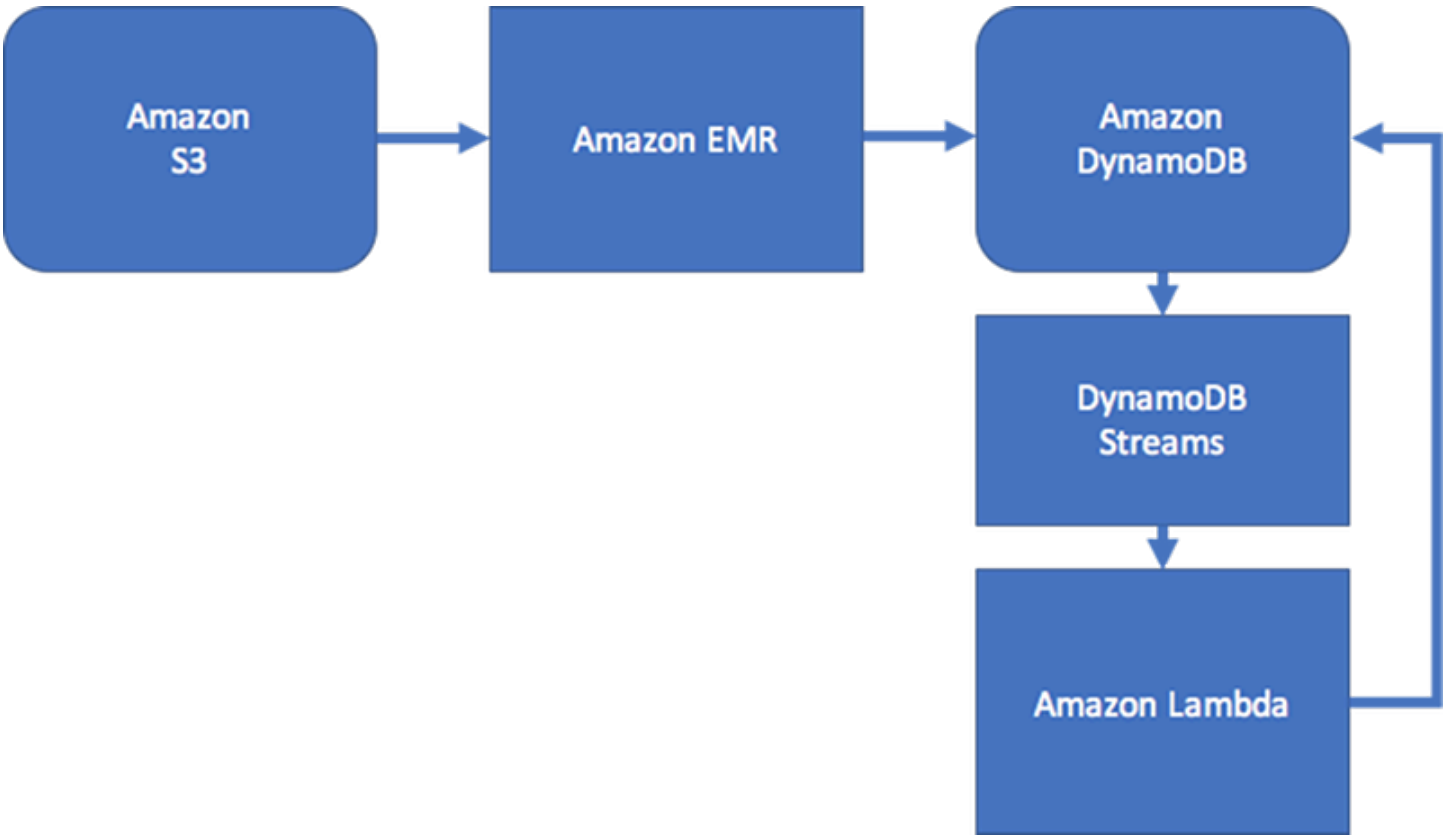
The second global secondary index uses `TypeTarget` as its partition key for reverse lookups. For example, you can find all people who list `Person-2` as a friend by querying for `TypeTarget=Friend-Person-2`.

As you insert items into the table, you can use an intelligent sharding strategy to distribute item sets with large aggregations (birthdate, skill) across as many logical partitions on the global secondary indexes as are needed to avoid hot read/write problems.

With this combination of design patterns, you get a solid datastore for highly efficient real-time graph workflows. You can use it to build high-performance neighbor entity state and edge aggregation queries for recommendation engines, social-networking applications, node rankings, subtree aggregations, and other common graph use cases.

If your use case isn't sensitive to real-time data consistency, you can use a scheduled Amazon EMR process to populate edges with relevant graph summary aggregations for your workflows. If your application doesn't need to know immediately when an edge is added to the graph, you can use a scheduled process to aggregate results.

To maintain some level of consistency, the design could include Amazon DynamoDB Streams and AWS Lambda to process edge updates. It could also use an Amazon EMR job to validate results on a regular interval. This approach is illustrated by the following diagram. It is commonly used in social networking applications, where the cost of a real-time query is high and the need to immediately know individual user updates is low.



IT service-management (ITSM) and security applications generally need to respond in real time to entity state changes composed of complex edge aggregations. Such applications need a system that can support real-time multiple node aggregations of second- and third-level relationships, or complex edge traversals. If your use case requires these types of real-time graph query workflows, we recommend that you consider using Amazon Neptune to manage these workflows.

> **Note**
>
> If you need to query highly connected datasets or traverse multiple nodes (multi-hop queries) with millisecond latency, consider using Amazon Neptune. Amazon Neptune is a purpose-built, high-performance graph database engine. It is optimized for storing billions of relationships and querying the graph with millisecond latency.

Best practices for querying and scanning data in DynamoDB

This section covers some best practices for using `Query` and `Scan` operations in Amazon DynamoDB.

Performance considerations for scans

In general, `Scan` operations are less efficient than other operations in DynamoDB. A `Scan` operation always scans the entire table or secondary index. It then filters out values to provide the result you want, essentially adding the extra step of removing data from the result set.

If possible, you should avoid using a `Scan` operation on a large table or index with a filter that removes many results. Also, as a table or index grows, the `Scan` operation slows. The `Scan` operation examines every item for the requested values and can use up the provisioned throughput for a large table or index in a single operation. For faster response times, design your tables and indexes so that your applications can use `Query` instead of `Scan`. (For tables, you can also consider using the `GetItem` and `BatchGetItem` APIs.)

Alternatively, you can design your application to use `Scan` operations in a way that minimizes the impact on your request rate. This can include modeling when it might be more efficient to use a global secondary index instead of a `Scan` operation. Further information on this process is in the following video.

Modeling low velocity access patterns

Avoiding sudden spikes in read activity

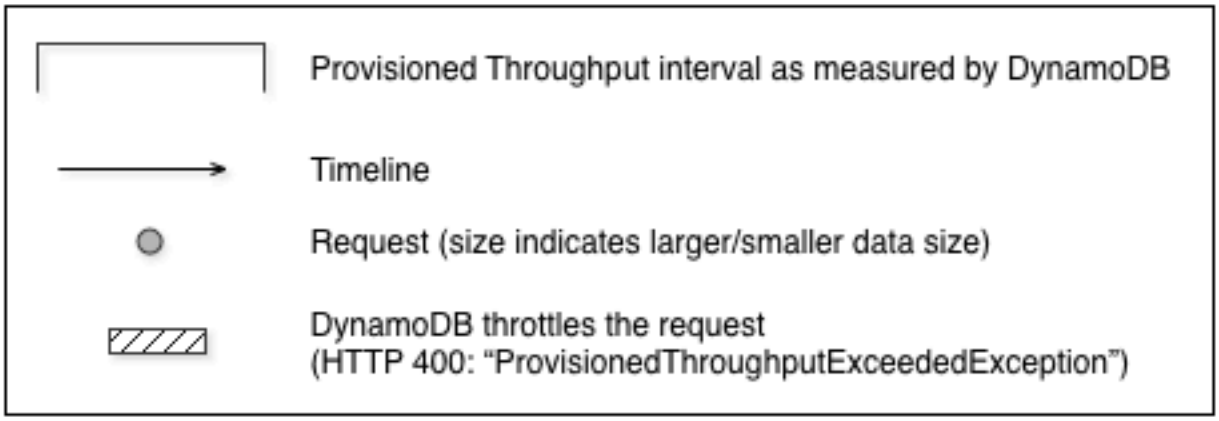
When you create a table, you set its read and write capacity unit requirements. For reads, the capacity units are expressed as the number of strongly consistent 4 KB data read requests per second. For eventually consistent reads, a read capacity unit is two 4 KB read requests per second. A `Scan` operation performs eventually consistent reads by default, and it can return up to 1 MB (one page) of data. Therefore, a single `Scan` request can consume (1 MB page size / 4 KB item size) / 2 (eventually consistent reads) = 128 read operations. If you request strongly consistent reads instead, the `Scan` operation would consume twice as much provisioned throughput—256 read operations.

This represents a sudden spike in usage, compared to the configured read capacity for the table. This usage of capacity units by a scan prevents other potentially more important requests for the same table from using the available capacity units. As a result, you likely get a `ProvisionedThroughputExceeded` exception for those requests.

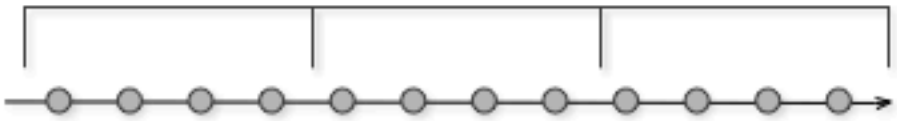
The problem is not just the sudden increase in capacity units that the `Scan` uses. The scan is also likely to consume all of its capacity units from the same partition because the scan requests read

items that are next to each other on the partition. This means that the request is hitting the same partition, causing all of its capacity units to be consumed, and throttling other requests to that partition. If the request to read data is spread across multiple partitions, the operation would not throttle a specific partition.

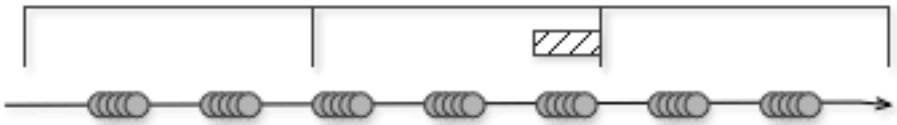
The following diagram illustrates the impact of a sudden spike of capacity unit usage by `Query` and `Scan` operations, and its impact on your other requests against the same table.



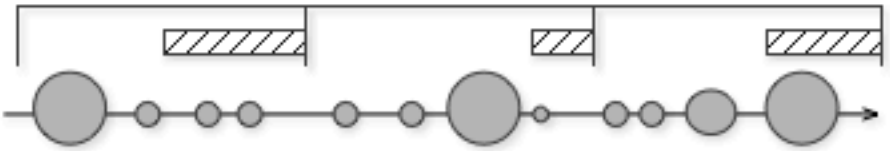
1. Good: Even distribution of requests and size



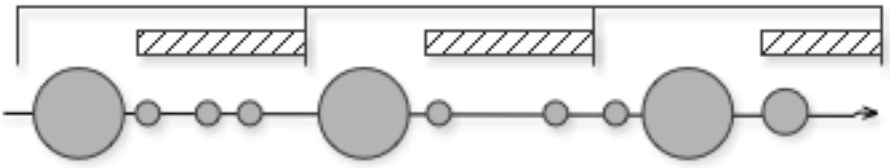
2. Not as Good: Frequent requests in bursts



3. Bad: A few random large requests



4. Bad: Large scan operations



As illustrated here, the usage spike can impact the table's provisioned throughput in several ways:

1. Good: Even distribution of requests and size

2. Not as good: Frequent requests in bursts
3. Bad: A few random large requests
4. Bad: Large scan operations

Instead of using a large `Scan` operation, you can use the following techniques to minimize the impact of a scan on a table's provisioned throughput.

- **Reduce page size**

  Because a Scan operation reads an entire page (by default, 1 MB), you can reduce the impact of the scan operation by setting a smaller page size. The `Scan` operation provides a *Limit* parameter that you can use to set the page size for your request. Each `Query` or `Scan` request that has a smaller page size uses fewer read operations and creates a "pause" between each request. For example, suppose that each item is 4 KB and you set the page size to 40 items. A `Query` request would then consume only 20 eventually consistent read operations or 40 strongly consistent read operations. A larger number of smaller `Query` or `Scan` operations would allow your other critical requests to succeed without throttling.
- **Isolate scan operations**

  DynamoDB is designed for easy scalability. As a result, an application can create tables for distinct purposes, possibly even duplicating content across several tables. You want to perform scans on a table that is not taking "mission-critical" traffic. Some applications handle this load by rotating traffic hourly between two tables—one for critical traffic, and one for bookkeeping. Other applications can do this by performing every write on two tables: a "mission-critical" table, and a "shadow" table.

Configure your application to retry any request that receives a response code that indicates you have exceeded your provisioned throughput. Or, increase the provisioned throughput for your table using the `UpdateTable` operation. If you have temporary spikes in your workload that cause your throughput to exceed, occasionally, beyond the provisioned level, retry the request with exponential backoff. For more information about implementing exponential backoff, see Error retries and exponential backoff.

Taking advantage of parallel scans

Many applications can benefit from using parallel `Scan` operations rather than sequential scans. For example, an application that processes a large table of historical data can perform a parallel

scan much faster than a sequential one. Multiple worker threads in a background "sweeper" process could scan a table at a low priority without affecting production traffic. In each of these examples, a parallel `Scan` is used in such a way that it does not starve other applications of provisioned throughput resources.

Although parallel scans can be beneficial, they can place a heavy demand on provisioned throughput. With a parallel scan, your application has multiple workers that are all running `Scan` operations concurrently. This can quickly consume all of your table's provisioned read capacity. In that case, other applications that need to access the table might be throttled.

A parallel scan can be the right choice if the following conditions are met:

- The table size is 20 GB or larger.
- The table's provisioned read throughput is not being fully used.
- Sequential `Scan` operations are too slow.

Choosing TotalSegments

The best setting for `TotalSegments` depends on your specific data, the table's provisioned throughput settings, and your performance requirements. You might need to experiment to get it right. We recommend that you begin with a simple ratio, such as one segment per 2 GB of data. For example, for a 30 GB table, you could set `TotalSegments` to 15 (30 GB / 2 GB). Your application would then use 15 workers, with each worker scanning a different segment.

You can also choose a value for `TotalSegments` that is based on client resources. You can set `TotalSegments` to any number from 1 to 1000000, and DynamoDB lets you scan that number of segments. For example, if your client limits the number of threads that can run concurrently, you can gradually increase `TotalSegments` until you get the best `Scan` performance with your application.

Monitor your parallel scans to optimize your provisioned throughput use, while also making sure that your other applications aren't starved of resources. Increase the value for `TotalSegments` if you don't consume all of your provisioned throughput but still experience throttling in your `Scan` requests. Reduce the value for `TotalSegments` if the `Scan` requests consume more provisioned throughput than you want to use.

Best practices for DynamoDB table design

General design principles in Amazon DynamoDB recommend that you keep the number of tables you use to a minimum. In the majority of cases, we recommend that you consider using a single table. However if a single or small number of tables are not viable, these guidelines might be of use.

- The per account limit cannot be increased above 10,000 tables per account. If your application requires more tables, plan for distributing the tables across multiple accounts. For more information see service, account, and table quotas in Amazon DynamoDB.
- Consider control plane limits for concurrent control plane operations that might impact your table management.
- Work with AWS solution architects to validate your design patterns for multi-tenant designs.

Using DynamoDB global tables

Global tables build on Amazon DynamoDB's global footprint to provide you with a fully managed, multi-Region, and multi-active database that can deliver fast and local, read and write performance for massively scaled, global applications. Global tables replicate your DynamoDB tables automatically across your choice of AWS Regions. No application changes are required because global tables use existing DynamoDB APIs. There are no upfront costs or commitments for using global tables, and you pay only for the resources you use.

This guide explains how to use DynamoDB global tables effectively. It provides key facts about global tables, explains the feature's primary use cases, describes the two consistency modes, introduces a taxonomy of three different write models you should consider, walks through the four main request routing choices you might implement, discusses ways to evacuate a Region that's live or a Region that's offline, explains how to think about throughput capacity planning, and provides a checklist of things to consider when you deploy global tables.

This guide fits into a larger context of AWS multi-Region deployments, as covered in the AWS Multi-Region Fundamentals whitepaper and the Data resiliency design patterns with AWS video.

Key facts about DynamoDB global table design

- There are two versions of global tables: the current version Global Tables version 2019.11.21 (Current) (sometimes called "V2"), and Global tables version 2017.11.29 (Legacy) (sometimes called "V1"). This guide focuses exclusively on the current version.
- DynamoDB (without global tables) is a Regional service, which means that it is highly available and intrinsically resilient to failures of infrastructure, including the failure of an entire Availability Zone. A single-Region DynamoDB table is designed for 99.99% availability. For more information, see the DynamoDB service-level agreement (SLA).
- A DynamoDB global table replicates its data between two or more Regions. A multi-Region DynamoDB table is designed for 99.999% availability. With proper planning, global tables can help create an architecture that is resilient to Regional failures.
- DynamoDB doesn't have a global endpoint. All requests are made to a Regional endpoint that accesses the global table instance that's local to that Region.
- Calls to DynamoDB should not go across Regions. The best practice is for an application that is homed to one Region to directly access only the local DynamoDB endpoint for its Region. If problems are detected within a Region (in the DynamoDB layer or in the surrounding stack), end user traffic should be routed to a different application endpoint that's hosted in a different Region. Global tables make sure that the application homed in every Region has access to the same data.

Consistency modes

When you create a global table, you configure its consistency mode. Global tables support two consistency modes: multi-Region eventual consistency (MREC) and multi-Region strong consistency (MRSC) which was introduced in June 2025.

If you don't specify a consistency mode when you create a global table, the global table defaults to MREC. A global table can't contain replicas that are configured with different consistency modes. You can't change a global table's consistency mode after its creation. Multi-account global tables support MREC only.

Key facts about MREC

- Global tables that use MREC employ an active-active replication model. From the perspective of DynamoDB, the table in each Region has equal standing to accept read and write requests. After receiving a write request, the local replica table replicates the write operation to other participating remote Regions in the background.
- Items are replicated individually. Items that are updated within a single transaction might not be replicated together.
- Each table partition in the source Region replicates its write operations in parallel with every other partition. The sequence of write operations within a remote Region might not match the sequence of write operations that happened within the source Region. For more information about table partitions, see the blog post Scaling DynamoDB: How partitions, hot keys, and split for heat impact performance.
- A newly written item is usually propagated to all replica tables within a second. Nearby Regions tend to propagate faster.
- Amazon CloudWatch provides a `ReplicationLatency` metric for each Region pair. It is calculated by looking at arriving items, comparing their arrival time with their initial write time, and computing an average. Timings are stored within CloudWatch in the source Region. Viewing the average and maximum timings can be useful for determining the average and worst-case replication lag. There is no SLA on this latency.
- If an individual item is updated at about the same time (within this `ReplicationLatency` window) in two different Regions, and the second write operation happens before the first write operation was replicated, there's a potential for write conflicts. Global tables that use MREC resolve such conflicts by using a last writer wins mechanism, based on the timestamp of the write operations. The first operation "loses" to the second operation. These conflicts aren't recorded in CloudWatch or AWS CloudTrail.

- Each item has a last write timestamp held as a private system property. The last writer wins approach is implemented by using a conditional write operation that requires the incoming item's timestamp to be greater than the existing item's timestamp.
- A global table replicates all items to all participating Regions. If you want to have different replication scopes, you can create multiple global tables and assign each table different participating Regions.
- The local Region accepts write operations even if the replica Region is offline or `ReplicationLatency` grows. The local table continues to attempt replicating items to the remote table until each item succeeds.
- In the unlikely event that a Region goes fully offline, when it comes back online later, all pending outbound and inbound replications will be retried. No special action is required to bring the tables back in sync. The *last writer wins* mechanism ensures that the data eventually becomes consistent.
- You can add a new Region to a DynamoDB MREC table at any time. DynamoDB handles the initial sync and ongoing replication. You can also remove a Region (even the original Region), and this will delete the local table in that Region.

Key facts about MRSC

- Global tables that use MRSC also employ an active-active replication model. From the perspective of DynamoDB, the table in each Region has equal standing to accept read and write requests. Item changes in an MRSC global table replica are **synchronously** replicated to at least one other Region before the write operation returns a successful response.
- Strongly consistent read operations on any MRSC replica always return the latest version of an item. Conditional write operations always evaluate the condition expression against the latest version of an item. Updates always operate against the latest version of an item.
- Eventually consistent read operations on an MRSC replica might not include changes that recently occurred in another Region, and might not even include changes that very recently occurred in the same Region.
- A write operation fails with a `ReplicatedWriteConflictException` exception when it attempts to modify an item that is already being modified in another Region. Write operations that fail with the `ReplicatedWriteConflictException` exception can be retried and will succeed if the item is no longer being modified in another Region.

- With MRSC, latencies are higher for write operations and for strongly consistent read operations. These operations require cross-Region communication. This communication can add latency that increases based on the round-trip latency between the Region being accessed and the nearest Region participating in the global table. For more information, see the AWS re:Invent 2024 presentation, Multi-Region strong consistency with DynamoDB global tables. Eventually consistent read operations experience no extra latency.
- Items are replicated individually. Global tables using MRSC do not support the transaction APIs.
- A MRSC global table must be deployed in exactly three Regions. You can configure a MRSC global table with three replicas, or with two replicas and one witness. A witness is a component of an MRSC global table that contains recent data written to global table replicas. A witness provides an optional alternative to a full replica while supporting MRSC's availability architecture. You can't perform read or write operations on a witness. A witness doesn't incur storage or write costs. A witness is located within a different Region from the two replicas.
- To create an MRSC global table, you add one replica and a witness, or add two replicas to an existing DynamoDB table that contains no data. You cannot add additional replicas to an existing MRSC global table. You can't delete a single replica or a witness from an MRSC global table. You can delete two replicas, or delete one replica and a witness, from an MRSC global table. The second scenario converts the remaining replica to a single-Region DynamoDB table.
- You can determine whether an MRSC global table has a witness configured, and which Region in which it's configured, from the output of the DescribeTable API. The witness is owned and managed by DynamoDB and doesn't appear in your AWS account in the Region where it's configured.
- MRSC global tables are available in the following Region sets:
  - US Region set: US East (N. Virginia), US East (Ohio), US West (Oregon)
  - EU Region set: Europe (Ireland), Europe (London), Europe (Paris), Europe (Frankfurt)
  - AP Region set: Asia Pacific (Tokyo), Asia Pacific (Seoul), and Asia Pacific (Osaka)
- MRSC global tables can't span Region sets. For example, an MRSC global table can't contain replicas from both US and EU Region sets.
- Time to Live (TTL) isn't supported for MRSC global tables.
- Local secondary indexes (LSIs) aren't supported for MRSC global tables. Global secondary indexes (GSIs) are supported, and reads from a GSI are eventually consistent.
- CloudWatch Contributor Insights information is only reported for the Region in which an operation occurred.

- The local Region accepts all read and write operations as long as there is a second Region that hosts a replica or witness to establish quorum. If a second Region isn't available, the local Region can only service eventually consistent reads.
- In the unlikely event that a Region goes fully offline, when it comes back online later, it will automatically catch up. Until it's caught up, write operations and strongly consistent read operations *only* to the catching up Region will return errors while requests to other Regions will continue to perform normally. Eventually consistent read operations to the catching up Region will return the data that has so far been propagated into the Region, with usual local consistency behavior between the leader node and local replicas. No special action is required to bring the tables back in sync.

MREC DynamoDB global table use cases

MREC global tables provides these benefits:

- **Lower-latency read operations.** Place a copy of the data closer to the end user to reduce network latency during read operations. The data is kept as fresh as the `ReplicationLatency` value.
- **Lower-latency write operations.** You can write to a nearby region to reduce network latency and the time taken to achieve the write. The write traffic must be carefully routed to ensure no conflicts. Techniques for routing are discussed in more detail in Routing strategies in DynamoDB.
- **Seamless Region migration.** You can add a new Region and delete the old Region to migrate a deployment from one Region to another without downtime at the data layer.

MREC and MRSC global tables both provide this benefit:

- **Increased resiliency and disaster recovery.** If a Region has degraded performance or a full outage, you can evacuate it. To evacuate means moving away some or all requests going to that Region. Using global tables increases the DynamoDB SLA for monthly uptime percentage from 99.99% to 99.999%. Using MREC supports a recovery point objective (RPO) and recovery time objective (RTO) measured in seconds. Using MRSC supports an RPO of zero.

  For example, Fidelity Investments presented at re:Invent 2022 on how they use DynamoDB global tables for their order management system. Their goal was to achieve reliably low latency processing at a scale they couldn't achieve with on-premises processing while also maintaining resilience to Availability Zone and Regional failures.

If your goal is resiliency and disaster recovery, MRSC tables have higher write latencies and higher strongly consistent read latencies, but support an RPO of zero. MREC global tables support an RPO equal to the replication delay between replicas, usually a few seconds depending on the replica Regions.

Key facts about multi-account global tables

With DynamoDB global tables, you can replicate data between tables in different AWS accounts. You can use multi-account global tables when security or governance controls require isolating workload Regions into separate AWS accounts. Accounts are a hard boundary, and separating a workload across multiple accounts reduces potential impact in account compromise scenarios. Your account can replicate data only to and from replicas in other accounts. You cannot delete those replicas or modify their point-in-time recovery (PITR) or backup settings. Therefore, if credentials in one account are compromised, only that account's replica of the data is affected.

Accounts also provide a hard boundary for cost allocation. Each account pays only for the resources and requests used by its own replica—reads, writes, storage, and data transfer. DynamoDB global tables don't charge for replication data transfer between Regions. If a different team uses the replica, a separate account provides clearer cost separation than tags alone.

- Multi-account global tables support only MREC.
- Conflict resolution uses the same last-writer-wins mechanism as same-account MREC global tables.
- Every replica in a multi-account global table **must** be in a different AWS account **and** Region. DynamoDB doesn't support same-Region replication.
- Because every replica must have a unique AWS account, a table must be single-Region before you add the first cross-account replica. An existing single-account global table must delete its replicas before becoming a multi-account global table.
- All replicas in the replication group must have a resource-based policy that allows the DynamoDB replication service principal (`replication.dynamodb.amazonaws.com`) to read and write data between replicas. Add this policy to the source replica before adding a new replica. You can use the DynamoDB console, the , an AWS SDK, or an infrastructure-as-code tool. For an example resource policy, see Setting up multi-account global tables.
- DynamoDB doesn't replicate point-in-time recovery (PITR) settings. For full resiliency in all accounts, enable PITR on every replica. This provides a recovery path if one account is compromised and malicious writes or deletes replicate to other accounts.

- If the source replica is encrypted with an AWS KMS key, you must update the key policy to allow the DynamoDB replication service principal (`replication.dynamodb.amazonaws.com`) permission to `kms:Decrypt`, `kms:ReEncrypt*`, `kms:GenerateDataKey*`, and `kms:DescribeKey`. You don't need these permissions when you use an AWS owned key. Multi-account global tables don't support AWS managed keys.
- To create a replica from the console, initiate the action in the destination account and destination Region.
- Encryption key management modes don't need to match between replicas.
- You can create replicas with AWS owned encryption keys through the console. Use the or an AWS SDK if you need to create a replica with a customer managed key.
- You cannot delete the source replica for the first 24 hours after creating a multi-account global table. Otherwise, you can delete your replica from the replication group or change your replica's non-replicated settings at any time. You cannot, however, delete or modify replicas in other accounts.

Write modes with DynamoDB global tables

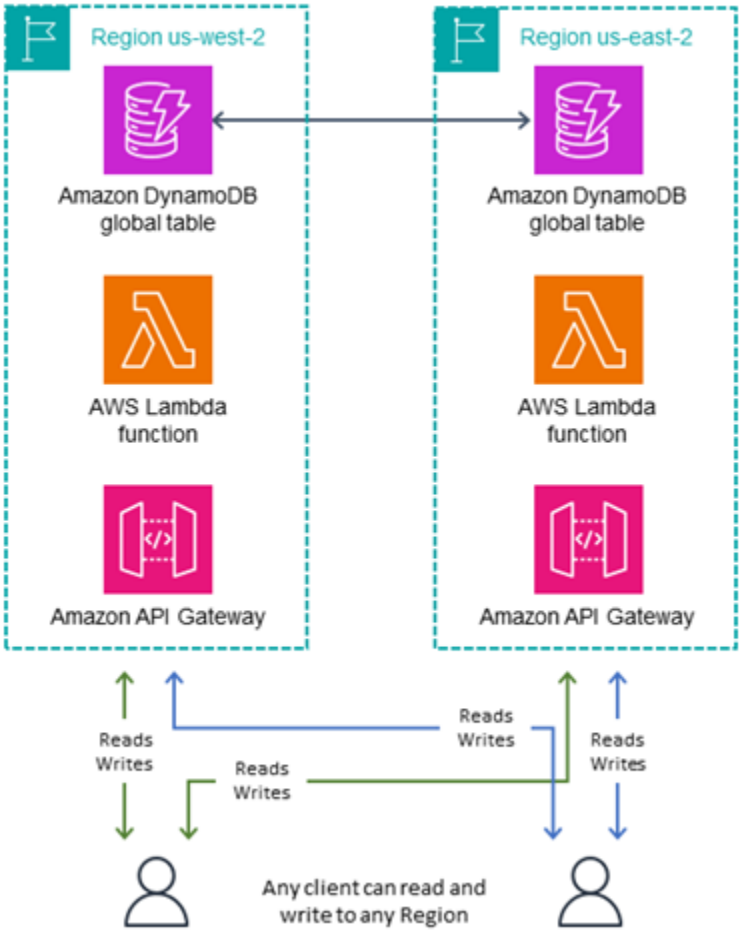
Global tables are always active-active at the table level. However, especially for MREC tables, you might want to treat them as active-passive by controlling how you route write requests. For example, you might decide to route write requests to a single Region to avoid potential write conflicts that can happen with MREC tables.

There are three main managed write patterns, as explained in the next three sections. You should consider which write pattern fits your use case. This choice affects how you route requests, evacuate a Region, and handle disaster recovery. The guidance in later sections depends on your application's write mode.

Write to any Region mode (no primary)

The *write to any Region* mode, illustrated in the following diagram, is fully active-active and doesn't impose restrictions on where a write might occur. Any Region might accept a write at any time. This is the simplest mode, but it can only be used with some types of applications. This mode is suitable for all MRSC tables. It's also suitable for MREC tables when all writers are idempotent, and therefore safely repeatable so that concurrent or repeated write operations across Regions are not in conflict. For example, when a user updates their contact data. This mode also works well for a special case of being idempotent, an append-only dataset where all writes are unique inserts under

a deterministic primary key. Lastly, this mode is suitable for MREC where the risk of conflicting writes would be acceptable.



The *write to any Region* mode is the most straightforward architecture to implement. Routing is easier because any Region can be the write target at any time. Failover is easier, because with MRSC tables, the items are always synchronized, and with MRSC tables, any recent writes can be replayed any number of times to any secondary Region. Where possible, you should design for this write mode.

For example, several video streaming services use global tables for tracking bookmarks, reviews, watch status flags, and so on. These deployments use MREC tables because they need replicas scattered around the world, with each replica providing low-latency read and write operations. These deployments can use the *write to any Region* mode as long as they make sure that every write operation is idempotent. This will be the case if every update—for example, setting a new latest time code, assigning a new review, or setting a new watch status—assigns the user's new state directly, and the next correct value for an item doesn't depend on its current value. If, by chance, the user's write requests are routed to different Regions, the last write operation will

persist and the global state will settle according to the last assignment. Read operations in this mode will eventually become consistent, delayed by the latest `ReplicationLatency` value.

In another example, a financial services firm uses global tables as part of a system to maintain a running tally of debit card purchases for each customer, to calculate that customer's cash-back rewards. They want to keep a `RunningBalance` item per customer. This write mode is not naturally idempotent because as transactions stream in, they modify the balance by using an `ADD` expression where the new correct value depends on the current value. By using MRSC tables they can still *write to any Region*, because every `ADD` call always operates against the very latest value of the item.

A third example involves a company that provides online ad placement services. This company decided that a low risk of data loss would be acceptable to achieve the design simplifications of the *write to any Region* mode. When they serve ads, they have just a few milliseconds to retrieve enough metadata to determine which ad to show, and then to record the ad impression so they don't repeat the same ad soon. They use global tables to get both low-latency read operations for end users across the world and low-latency write operations. They record all ad impressions for a user within a single item, which is represented as a growing list. They use one item instead of appending to an item collection, so they can remove older ad impressions as part of each write operation without paying for a delete operation. This write operation is not idempotent; if the same end user sees ads served out of multiple Regions at approximately the same time, there's a chance that one write operation for an ad impression could overwrite another. The risk is that a user might see an ad repeated once in a while. They decided that this is acceptable.

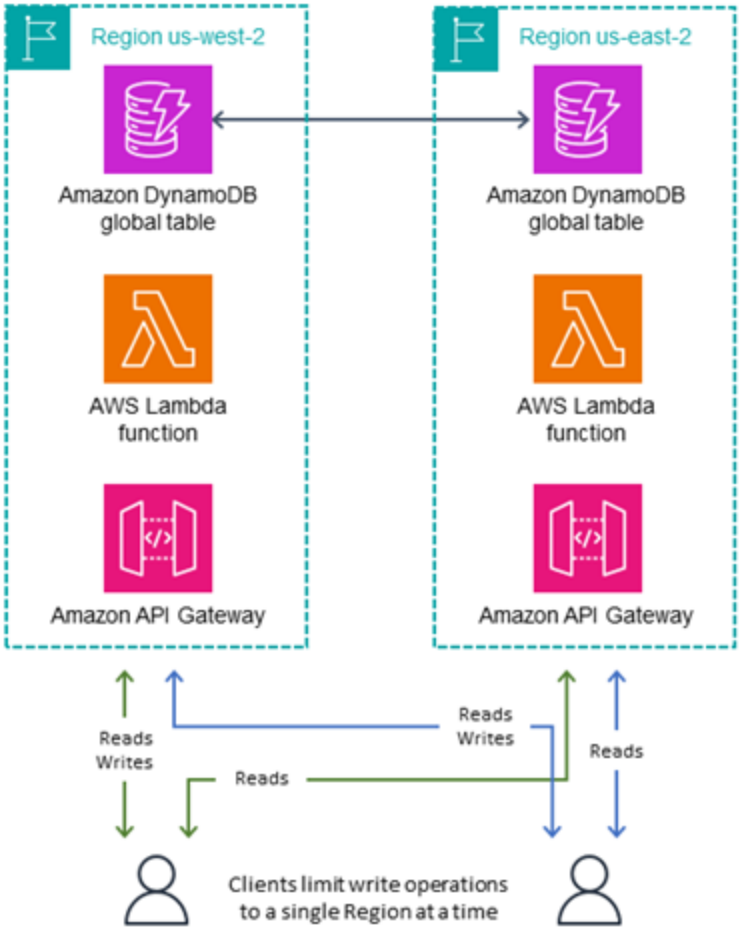
Write to one Region (single primary)

The *write to one Region* mode, illustrated in the following diagram, is active-passive and routes all table writes to a single active region. Note that DynamoDB doesn't have a notion of a single active region; the application routing outside DynamoDB manages this. The *write to one Region* mode works well for MREC tables that need to avoid write conflicts by ensuring that write operations flow only to one Region at a time. This write mode helps when you want to use conditional expressions and can't use MRSC for some reason, or when you need to perform transactions. These expressions aren't possible unless you know that you're acting against the latest data, so they require sending all write requests to a single Region that has the latest data.

When you use an MRSC table, you might choose to generally write to one Region for convenience. For example, this can help minimize your infrastructure build-out beyond DynamoDB. The write mode would still be write to any Region because with MRSC you could safely write to any Region at

any time without concern of conflict resolution that would cause MREC tables to choose to *write to one Region*.

Eventually consistent reads can go to any replica Regions to achieve lower latencies. Strongly consistent reads must go to the single primary Region.



It's sometimes necessary to change the active Region in response to a Regional failure. Some users change the currently active Region on a regular schedule, such as implementing a follow-the-sun deployment. This places the active Region near the geography that has the most activity (usually where it's daytime, thus the name), which results in the lowest latency read and write operations. It also has the side benefit of calling the Region-changing code daily and making sure that it's well tested before any disaster recovery.

The passive Region(s) might keep a downscaled set of infrastructure surrounding DynamoDB that gets built up only if it becomes the active Region. This guide doesn't cover pilot light and warm standby designs. For a more information, see Disaster Recovery (DR) Architecture on AWS, Part III: Pilot Light and Warm Standby.

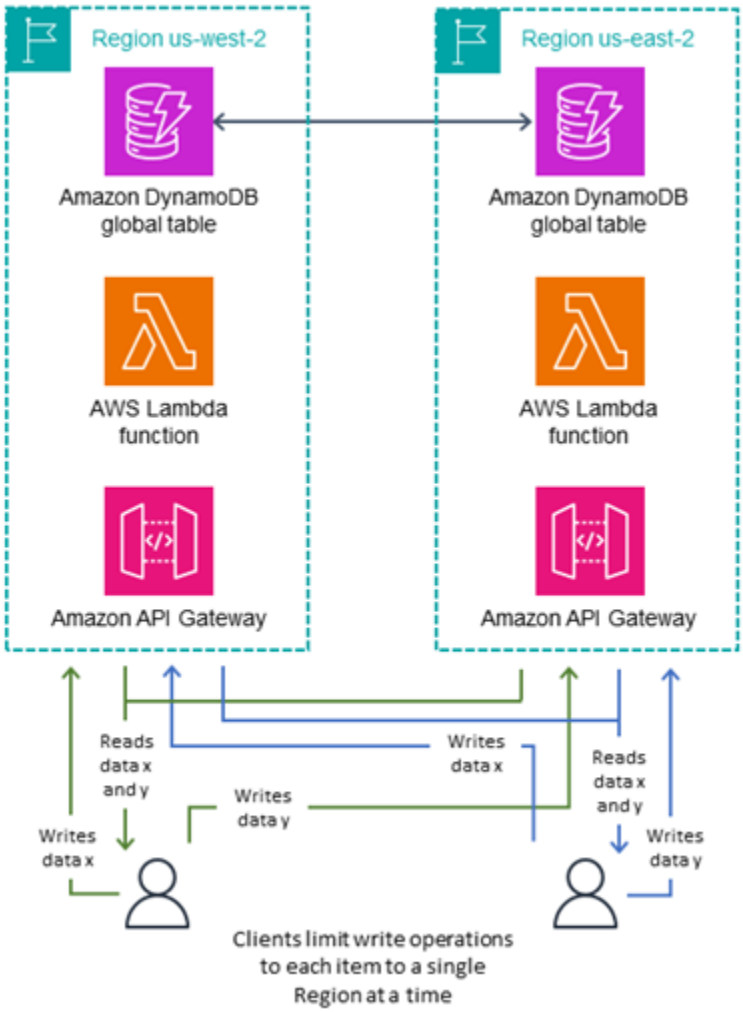
Using the *write to one Region* mode works well when you use global tables for low-latency globally distributed read operations. An example is a large social media company that needs to have the same reference data available in every Region around the world. They don't update the data often, but when they do, they write to only one Region to avoid any potential write conflicts. Read operations are always allowed from any Region.

As another example, consider the financial services company discussed earlier that implemented the daily cash-back calculation. They used *write to any Region* mode to calculate the balance but *write to one Region* mode to track payments. This work requires transactions, which aren't supported in MRSC tables, so it works better with a separate MREC table and *write to one Region* mode.

Write to your Region (mixed primary)

The *write to your Region* write mode, illustrated in the following diagram, works with MREC tables. It assigns different data subsets to different home Regions and allows write operations to an item only through its home Region. This mode is active-passive but assigns the active Region based on the item. Every Region is primary for its own non-overlapping dataset, and write operations must be guarded to ensure proper locality.

This mode is similar to *write to one Region* except that it enables lower-latency write operations, because the data associated with each user can be placed in closer network proximity to that user. It also spreads the surrounding infrastructure more evenly between Regions and requires less work to build out infrastructure during a failover scenario, because all Regions have a portion of their infrastructure already active.



You can determine the home Region for items in several ways:

- **Intrinsic:** Some aspect of the data, such as a special attribute or a value embedded within its partition key, makes its home Region clear. This technique is described in the blog post Use Region pinning to set a home Region for items in an Amazon DynamoDB global table.
- **Negotiated:** The home Region of each dataset is negotiated in some external manner, such as with a separate global service that maintains assignments. The assignment might have a finite duration after which it's subject to renegotiation.
- **Table-oriented:** Instead of creating a single replicating global table, you create the same number of global tables as replicating Regions. Each table's name indicates its home Region. In standard operations, all data is written to the home Region while other Regions keep a read-only copy. During a failover, another Region temporarily adopts write duties for that table.

For example, imagine that you're working for a gaming company. You need low-latency read and write operations for all gamers around the world. You assign each gamer to the Region that's closest to them. That Region takes all their read and write operations, ensuring strong read-after-write consistency. However, when a gamer travels or if their home Region suffers an outage, a complete copy of their data is available in alternative Regions, and the gamer can be assigned to a different home Region.

As another example, imagine that you're working at a video conferencing company. Each conference call's metadata is assigned to a particular Region. Callers can use the Region that's closest to them for lowest latency. If there's a Region outage, using global tables allows quick recovery because the system can move the processing of the call to a different Region where a replicated copy of the data already exists.

To summarize

- Write to any Region mode is suitable for MRSC tables and idempotent calls to MREC tables.
- Write to one Region mode is suitable for non-idempotent calls to MREC tables.
- Write to your Region mode is suitable for non-idempotent calls to MREC tables, where it's important to have clients write to a Region that's close to them.

Routing strategies in DynamoDB

Perhaps the most complex piece of a global table deployment is managing request routing. Requests must first go from an end user to a Region that's chosen and routed in some manner. The request encounters some stack of services in that Region, including a compute layer that perhaps consists of a load balancer backed by an AWS Lambdafunction, container, or Amazon Elastic Compute Cloud (Amazon EC2) node, and possibly other services including another database. That compute layer communicates with DynamoDB It should do that by using the local endpoint for that Region. The data in the global table replicates to all other participating Regions, and each Region has a similar stack of services around its DynamoDB table.

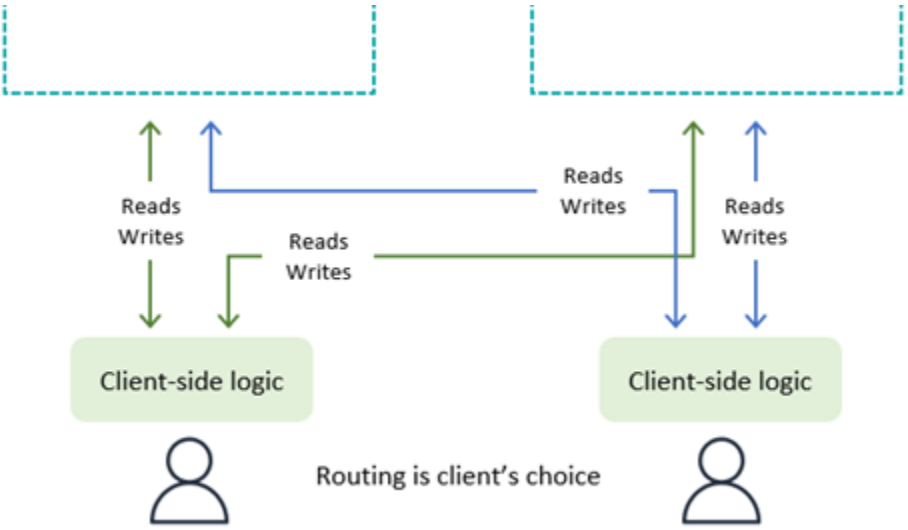
The global table provides each stack in the various Regions with a local copy of the same data. You might consider designing for a single stack in a single Region and anticipate making remote calls to a secondary Region's DynamoDB endpoint if there's an issue with the local DynamoDB table. This is not best practice. If there's an issue in one Region that's caused by DynamoDB (or, more likely, caused by something else in the stack or by another service that depends on DynamoDB), it's best to route the end user to another Region for processing and use that other Region's compute

layer, which will talk to its local DynamoDB endpoint. This approach routes around the problematic Region entirely. To ensure resiliency, you need replication across multiple Regions: replication of the compute layer as well as the data layer.

There are numerous alternative techniques to route an end user request to a Region for processing. The optimum choice depends on your write mode and your failover considerations. This section discusses four options: client-driven, compute-layer, Route 53, and Global Accelerator.

Client-driven request routing

With client-driven request routing, illustrated in the following diagram, the end user client (an application, a web page with JavaScript, or another client) keeps track of the valid application endpoints (for example, an Amazon API Gateway endpoint rather than a literal DynamoDB endpoint) and uses its own embedded logic to choose the Region to communicate with. It might choose based on random selection, lowest observed latencies, highest observed bandwidth measurements, or locally performed health checks.



As an advantage, client-driven request routing can adapt to things such as real-world public internet traffic conditions to switch Regions if it notices any degraded performance. The client must be aware of all potential endpoints, but launching a new Regional endpoint is not a frequent occurrence.

With *write to any Region* mode, a client can unilaterally select its preferred endpoint. If its access to one Region becomes impaired, the client can route to another endpoint.

With the *write to one Region* mode, the client will need a mechanism to route its writes to the currently active region. This could be as basic as empirically testing which region is presently

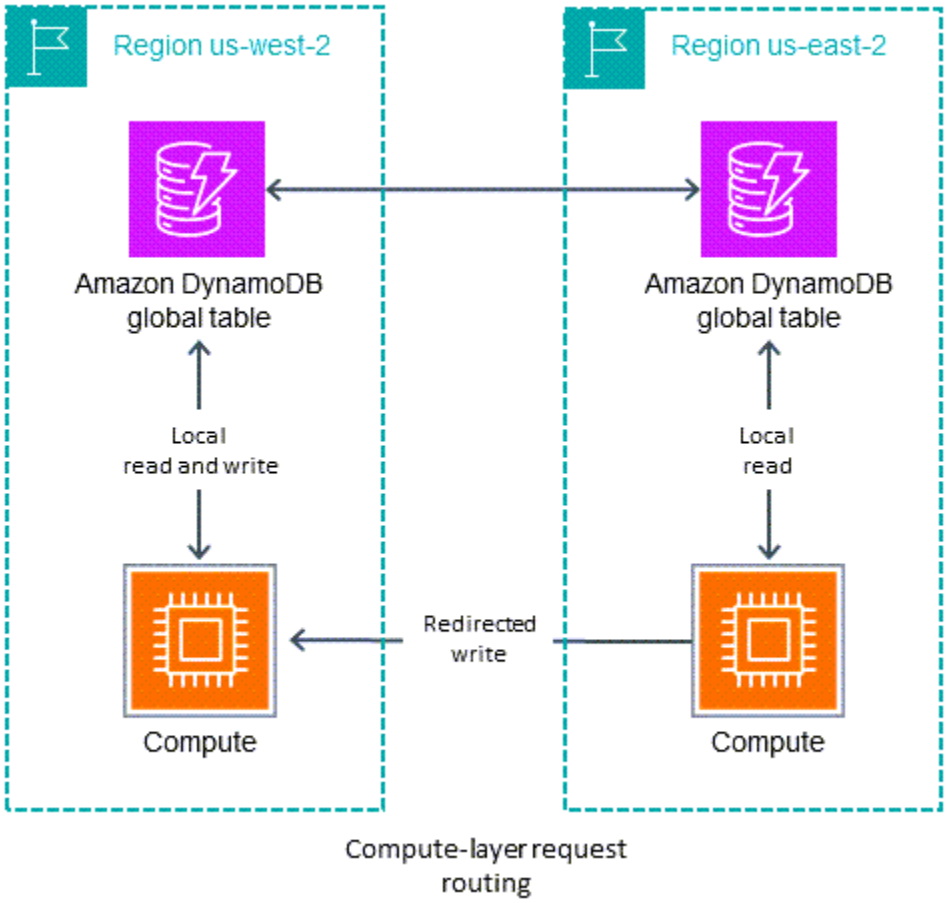
accepting writes (noting any write rejections and falling back to an alternate) or as complex as calling a global coordinator to query for the current application state (perhaps built on the Amazon Application Recovery Controller (ARC) (ARC) routing control which provides a 5-region quorum-driven system to maintain global state for needs such as this). The client can decide if reads can go to any Region for eventual consistency or must be routed to the active region for strong consistency. For further information see How Route 53 works.

With the *write to your Region* mode, the client needs to determine the home region for the data set it's working against. For example, if the client corresponds to a user account and each user account is homed to a Region, the client can request the appropriate endpoint from a global login system.

For example, a financial services company that helps users manage their business finances through the web could use global tables with a *write to your Region* mode. Each user must log in to a central service. That service returns credentials and the endpoint for the Region where those credentials will work. The credentials are valid for a short time. After that the webpage auto-negotiates a new login, which provides an opportunity to potentially redirect the user's activity to a new Region.

Compute-layer request routing

With compute-layer request routing, illustrated in the following diagram, the code that runs in the compute layer determines whether to process the request locally or pass it to a copy of itself that's running in another Region. When you use the *write to one Region* mode, the compute layer might detect that it's not the active Region and allow local read operations while forwarding all write operations to another Region. This compute layer code must be aware of data topology and routing rules, and enforce them reliably, based on the latest settings that specify which Regions are active for which data. The outer software stack within the Region doesn't have to be aware of how read and write requests are routed by the micro service. In a robust design, the receiving Region validates whether it is the current primary for the write operation. If it isn't, it generates an error that indicates that the global state needs to be corrected. The receiving Region might also buffer the write operation for a while if the primary Region is in the process of changing. In all cases, the compute stack in a Region writes only to its local DynamoDB endpoint, but the compute stacks might communicate with one another.

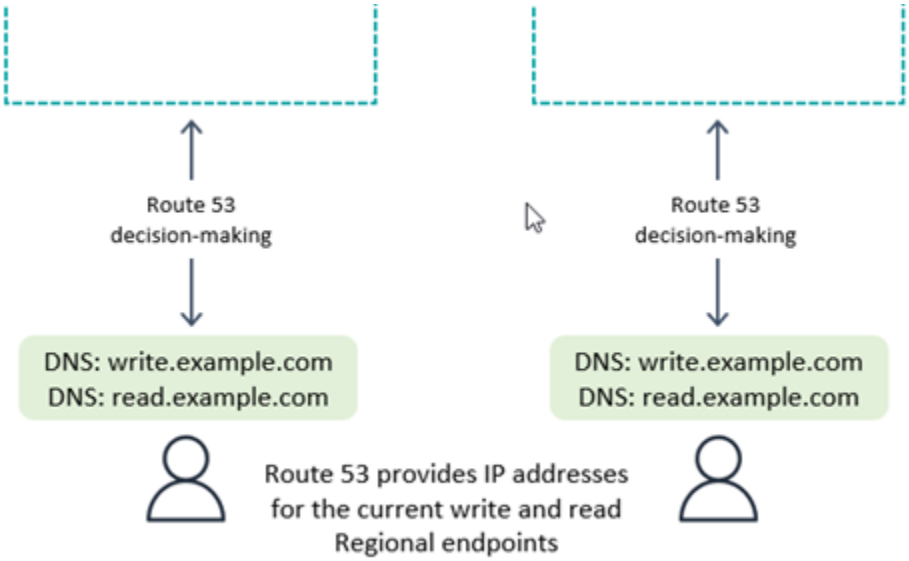


The Vanguard Group uses a system called Global Orchestration and Status Tool (GOaST) and a library called Global Multi-Region library (GMRlib) for this routing process, as presented at re:Invent 2022. They use a follow-the-sun single primary model. GOaST maintains the global state, similar to the ARC routing control discussed in the previous section. It uses a global table to track which Region is the primary Region and when the next primary switch is scheduled. All read and write operations go through GMRlib, which coordinates with GOaST. GMRlib allows read operations to be performed locally, at low latency. For write operations, GMRlib checks if the local Region is the current primary Region. If so, the write operation completes directly. If not, GMRlib forwards the write task to the GMRlib in the primary Region. That receiving library confirms that it also considers itself the primary Region and raises an error if it isn't, which indicates a propagation delay with the global state. This approach provides a validation benefit by not writing directly to a remote DynamoDB endpoint.

Route 53 request routing

Amazon Application Recovery Controller (ARC) is a Domain Name Service (DNS) technology. With Route 53, the client requests its endpoint by looking up a well-known DNS domain name,

and Route 53 returns the IP address corresponding to the regional endpoint(s) it thinks most appropriate. This is illustrated in the following diagram. Route 53 has a long list of routing policies it uses to determine the appropriate Region. It also can do failover routing to route traffic away from Regions that fail health checks.



With *write to any Region* mode, or if combined with the compute-layer request routing on the backend, Route 53 can be given full access to return the Region based on any complex internal rules such as the Region in closest network proximity, or closest geographic proximity, or any other choice.

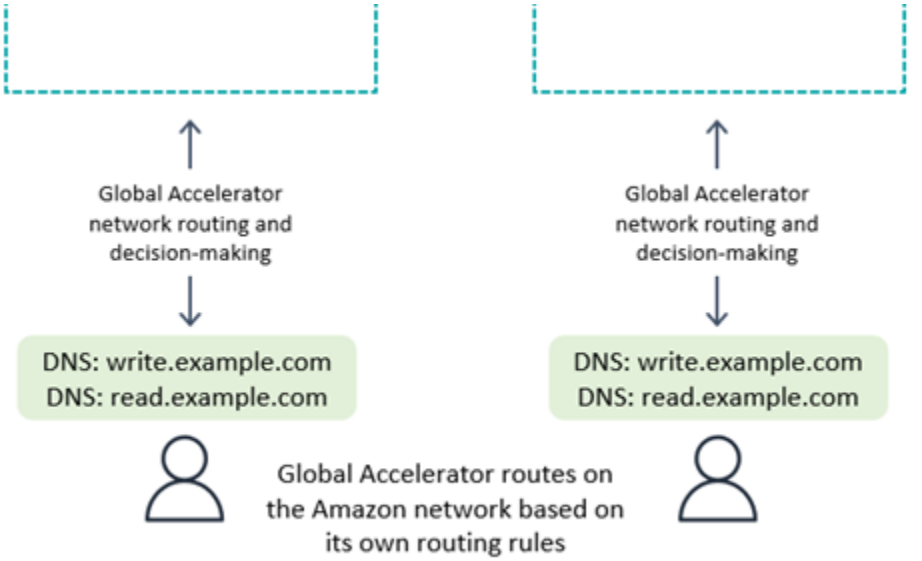
With *write to one Region* mode, you can configure Route 53 to return the currently active Region (using Route 53 ARC). If the client wants to connect to a passive Region (for example, for read operations), it could look up a different DNS name.

> **Note**
>
> Clients cache the IP addresses in the response from Route 53 for a time indicated by the time to live (TTL) setting on the domain name. A longer TTL extends the recovery time objective (RTO) for all clients to recognize the new endpoint. A value of 60 seconds is typical for failover use. Not all software perfectly adheres to DNS TTL expiration, and there might be multiple levels of DNS caching, such as at the operating system, virtual machine, and application.

With *write to your Region* mode, it's best to avoid Route 53 unless you're also using compute-layer request routing.

Global Accelerator request routing

With AWS Global Accelerator, illustrated in the following diagram, a client looks up the well-known domain name in Route 53. However, instead of getting back an IP address that corresponds to a Regional endpoint, the client receives an anycast static IP address which routes to the nearest AWS edge location. Starting from that edge location, all traffic gets routed on the private AWS network and to some endpoint (such as a load balancer or API Gateway) in a Region chosen by routing rules that are maintained within Global Accelerator. Compared with routing based on Route 53 rules, Global Accelerator request routing has lower latencies because it reduces the amount of traffic on the public internet. In addition, because Global Accelerator doesn't depend on DNS TTL expiration to change routing rules, it can adjust routing more quickly.



With *write to any Region* mode, or if combined with the compute-layer request routing on the back-end, Global Accelerator works seamlessly. The client connects to the nearest edge location and need not be concerned with which Region receives the request.

With *write to one Region* Global Accelerator routing rules must send requests to the currently active Region. You can use health checks that artificially report a failure on any Region that's not considered by your global system to be the active Region. As with DNS, it's possible to use an alternative DNS domain name for routing read requests if the requests can be from any Region.

With *write to your Region* mode, it's best to avoid Global Accelerator unless you're also using compute-layer request routing.

Evacuation processes

Evacuating a Region is the process of migrating activity, usually read and write activity or read activity, away from that Region.

Evacuating a live Region

You might decide to evacuate a live Region for a number of reasons: as part of usual business activity (for example, if you're using a follow-the-sun, write to one Region mode), due to a business decision to change the currently active Region, in response to failures in the software stack outside DynamoDB, or because you're encountering general issues such as higher than usual latencies within the Region.

With *write to any Region* mode, evacuating a live Region is straightforward. You can route traffic to alternative Regions by using any routing system and let the write operations in the evacuated Region replicate over as usual.

The write to one Region and write to your Region modes are usually used with MREC tables. Therefore, you must make sure that all write operations to the active Region have been fully recorded, stream processed, and globally propagated before starting write operations in the new active Region, to make sure that future write operations are processed against the latest version of the data.

Let's say that Region A is active and Region B is passive (either for the full table or for items that are homed in Region A). The typical mechanism to perform an evacuation is to pause write operations to A, wait long enough for those operations to have fully propagated to B, update the architecture stack to recognize B as active, and then resume write operations to B. There is no metric to indicate with absolute certainty that Region A has fully replicated its data to Region B. If Region A is healthy, pausing write operations to Region A and waiting 10 times the recent maximum value of the `ReplicationLatency` metric would typically be sufficient to determine that replication is complete. If Region A is unhealthy and shows other areas of increased latencies, you would choose a larger multiple for the wait time.

Evacuating an offline Region

There's a special case to consider: What if Region A goes fully offline without notice? This is extremely unlikely but should be considered nevertheless.

Evacuating an offline MRSC table

If this happens with an MRSC table, there is nothing special you need to do. MRSC tables support a recovery point objective (RPO) of zero. All successful write operations made to the MRSC table in the offline Region will be available in all other Region tables, so there's no potential gap in data even if the Region goes fully offline without notice. Business can continue using replicas located in the other Regions.

Evacuating an offline MREC table

If this happens with an MREC table, any write operations in Region A that were not yet propagated are held and propagated after Region A comes back online. The write operations aren't lost, but their propagation is indefinitely delayed.

How to proceed in this event is the application's decision. For business continuity, write operations might need to proceed to the new primary Region B. However, if an item in Region B receives an update while there is a pending propagation of a write operation for that item from Region A, the propagation is suppressed under the *last writer wins* model. Any update in Region B might suppress an incoming write request.

With the *write to any Region* mode, read and write operations can continue in Region B, trusting that the items in Region A will propagate to Region B eventually and recognizing the potential for missing items until Region A comes back online. When possible, such as with idempotent write operations, you should consider replaying recent write traffic (for example, by using an upstream event source) to fill in the gap of any potentially missing write operations and let the last writer wins conflict resolution suppress the eventual propagation of the incoming write operation.

With the other write modes, you have to consider the degree to which work can continue with a slightly out-of-date view of the world. Some small duration of write operations, as tracked by `ReplicationLatency`, will be missing until Region A comes back online. Can business move forward? In some use cases it can, but in others it might not without additional mitigation mechanisms.

For example, imagine that you have to maintain an available credit balance without interruption even after a full outage of a Region. You could split the balance into two different items, one homed in Region A and one in Region B, and start each with half the available balance. This would use the *write to your Region* mode. Transactional updates processed in each Region would write against the local copy of the balance. If Region A goes fully offline, work could still proceed with transaction processing in Region B, and write operations would be limited to the

balance portion held in Region B. Splitting the balance like this introduces complexities when the balance gets low or the credit has to be rebalanced, but it does provide one example of safe business recovery even with uncertain pending write operations.

As another example, imagine that you're capturing web form data. You can use Optimistic Concurrency Control (OCC) (OCC) to assign versions to data items and embed the latest version into the web form as a hidden field. On each submit, the write operation succeeds only if the version in the database still matches the version that the form was built against. If the versions don't match, the web form can be refreshed (or carefully merged) based on the current version in the database, and the user can proceed again. The OCC model usually protects against another client overwriting and producing a new version of the data, but it can also help during failover where a client might encounter older versions of data. Let's imagine that you're using the timestamp as the version. The form was first built against Region A at 12:00 but (after failover) tries to write to Region B and notices that the latest version in the database is 11:59. In this scenario, the client can either wait for the 12:00 version to propagate to Region B and then write on top of that version, or build on 11:59 and create a new 12:01 version (which, after writing, would suppress the incoming version after Region A recovers).

As a third example, a financial services company holds data about customer accounts and their financial transactions in a DynamoDB database. In the event of a complete Region A outage, they want to make sure that any write activity related to their accounts is either fully available in Region B, or they want to quarantine their accounts as known partial until Region A comes back online. Instead of pausing all business, they decided to pause business only to the tiny fraction of accounts that they determined had unpropagated transactions. To achieve this, they used a third Region, referred to here as Region C. Before they processed any write operations in Region A, they placed a succinct summary of those pending operations (for example, a new transaction count for an account) in Region C. This summary was sufficient for Region B to determine if its view was fully up to date. This action effectively locked the account from the time of writing in Region C until Region A accepted the write operations and Region B received them. The data in Region C wasn't used except as part of a failover process, after which Region B could cross-check its data with Region C to check if any of its accounts were out of date. Those accounts would be marked as quarantined until the Region A recovery propagated the partial data to Region B. If Region C were to fail, a new Region D could be spun up for use instead. The data in Region C was very transient, and after a few minutes Region D would have a sufficiently up-to-date record of the in-flight write operations to be fully useful. If Region B were to fail, Region A could continue accepting write requests in cooperation with Region C. This company was willing to accept higher latency writes (to two Regions: C and then A)

and was fortunate to have a data model where the state of an account could be succinctly summarized.

Throughput capacity planning for DynamoDB global tables

Migrating traffic from one Region to another requires careful consideration of DynamoDB table settings regarding capacity.

Here are some considerations for managing write capacity:

- A global table must be in on-demand mode or provisioned with auto scaling enabled.
- If provisioned with auto scaling, the write settings (minimum, maximum, and target utilization) are replicated across Regions. Although the auto scaling settings are synchronized, the actual provisioned write capacity can float independently between Regions.
- One reason you could see different provisioned write capacity is due to the TTL feature. When you enable TTL in DynamoDB, you can specify an attribute name whose value indicates the time of expiration for the item, in Unix epoch time format in seconds. After that time, DynamoDB can delete the item without incurring write costs. With global tables, you can configure TTL in any Region, and the setting is automatically replicated to other Regions that are associated with the global table. When an item is eligible for deletion through a TTL rule, that work can be done in any Region. The delete operation is performed without consuming write units on the source table, but the replica tables will get a replicated write of that delete operation and will incur replicated write unit costs. TTL isn't supported in MRSC tables.
- If you’re using auto scaling, make sure that the maximum provisioned write capacity setting is sufficiently high to handle all write operations as well as all potential TTL delete operations. Auto scaling adjusts each Region according to its write consumption. On-demand tables have no maximum provisioned write capacity setting, but the *table-level maximum write throughput limit* specifies the maximum sustained write capacity the on-demand table will allow. The default limit to 40,000, but it is adjustable. We recommend that you set it high enough to handle all write operations (including TTL write operations) that the on-demand table might need. This value must be the same across all participating Regions when you set up global tables.

Here are some considerations for managing read capacity:

- Read capacity management settings are allowed to differ between Regions because it’s assumed that different Regions might have independent read patterns. When you first add a global replica

to a table, the capacity of the source Region is propagated. After creation you can adjust the read capacity settings, which aren't transferred to the other side.

- When you use DynamoDB auto scaling, make sure that the maximum provisioned read capacity settings are sufficiently high to handle all read operations across all Regions. During standard operations the read capacity will perhaps be spread across Regions, but during failover the table should be able to automatically adapt to the increased read workload. On-demand tables have no maximum provisioned read capacity setting, but the *table-level maximum read throughput limit* specifies the maximum sustained read capacity the on-demand table will allow. The default limit is 40,000, but it is adjustable. We recommend that you set it high enough to handle all read operations that the table might need if all read operations were to route to this single Region.
- If a table in one Region doesn't usually receive read traffic but might have to absorb a large amount of read traffic after a failover, you can pre-warm the capacity of the to accept a higher level of read traffic.

ARC has readiness checks that can be useful for confirming that DynamoDB Regions have similar table settings and account quotas, whether or not you use Route 53 to route requests. These readiness checks can also help in adjusting account-level quotas to make sure they match.

Preparation checklist for DynamoDB global tables

Use the following checklist for decisions and tasks when you deploy global tables.

- Determine if your use case benefits more from an MRSC or MREC consistency mode. Do you need strong consistency, even with the higher latency and other tradeoffs?
- Determine how many and which Regions should participate in the global table. If you plan to use MRSC, decide if you want the third Region to be a replica or a witness.
- Determine your application's write mode. This is not the same as the consistency mode. For more information, see Write modes with DynamoDB global tables.
- Plan your Routing strategies in DynamoDB strategy, based on your write mode.
- Define your

  Evacuating a Region is the process of migrating activity, usually read and write activity or read activity, away from that Region.

Evacuating a live Region

You might decide to evacuate a live Region for a number of reasons: as part of usual business activity (for example, if you're using a follow-the-sun, write to one Region mode), due to a business decision to change the currently active Region, in response to failures in the software stack outside DynamoDB, or because you're encountering general issues such as higher than usual latencies within the Region.

With *write to any Region* mode, evacuating a live Region is straightforward. You can route traffic to alternative Regions by using any routing system and let the write operations in the evacuated Region replicate over as usual.

The write to one Region and write to your Region modes are usually used with MREC tables. Therefore, you must make sure that all write operations to the active Region have been fully recorded, stream processed, and globally propagated before starting write operations in the new active Region, to make sure that future write operations are processed against the latest version of the data.

Let's say that Region A is active and Region B is passive (either for the full table or for items that are homed in Region A). The typical mechanism to perform an evacuation is to pause write operations to A, wait long enough for those operations to have fully propagated to B, update the architecture stack to recognize B as active, and then resume write operations to B. There is no metric to indicate with absolute certainty that Region A has fully replicated its data to Region B. If Region A is healthy, pausing write operations to Region A and waiting 10 times the recent maximum value of the `ReplicationLatency` metric would typically be sufficient to determine that replication is complete. If Region A is unhealthy and shows other areas of increased latencies, you would choose a larger multiple for the wait time.

Evacuating an offline Region

There's a special case to consider: What if Region A goes fully offline without notice? This is extremely unlikely but should be considered nevertheless.

Evacuating an offline MRSC table

If this happens with an MRSC table, there is nothing special you need to do. MRSC tables support a recovery point objective (RPO) of zero. All successful write operations made to the MRSC table in the offline Region will be available in all other Region tables, so there's

no potential gap in data even if the Region goes fully offline without notice. Business can continue using replicas located in the other Regions.

Evacuating an offline MREC table

If this happens with an MREC table, any write operations in Region A that were not yet propagated are held and propagated after Region A comes back online. The write operations aren't lost, but their propagation is indefinitely delayed.

How to proceed in this event is the application's decision. For business continuity, write operations might need to proceed to the new primary Region B. However, if an item in Region B receives an update while there is a pending propagation of a write operation for that item from Region A, the propagation is suppressed under the *last writer wins* model. Any update in Region B might suppress an incoming write request.

With the *write to any Region* mode, read and write operations can continue in Region B, trusting that the items in Region A will propagate to Region B eventually and recognizing the potential for missing items until Region A comes back online. When possible, such as with idempotent write operations, you should consider replaying recent write traffic (for example, by using an upstream event source) to fill in the gap of any potentially missing write operations and let the last writer wins conflict resolution suppress the eventual propagation of the incoming write operation.

With the other write modes, you have to consider the degree to which work can continue with a slightly out-of-date view of the world. Some small duration of write operations, as tracked by `ReplicationLatency`, will be missing until Region A comes back online. Can business move forward? In some use cases it can, but in others it might not without additional mitigation mechanisms.

For example, imagine that you have to maintain an available credit balance without interruption even after a full outage of a Region. You could split the balance into two different items, one homed in Region A and one in Region B, and start each with half the available balance. This would use the *write to your Region* mode. Transactional updates processed in each Region would write against the local copy of the balance. If Region A goes fully offline, work could still proceed with transaction processing in Region B, and write operations would be limited to the balance portion held in Region B. Splitting the balance like this introduces complexities when the balance gets low or the credit has to be rebalanced, but it does provide one example of safe business recovery even with uncertain pending write operations.

As another example, imagine that you're capturing web form data. You can use Optimistic Concurrency Control (OCC) (OCC) to assign versions to data items and embed the latest version into the web form as a hidden field. On each submit, the write operation succeeds only if the version in the database still matches the version that the form was built against. If the versions don't match, the web form can be refreshed (or carefully merged) based on the current version in the database, and the user can proceed again. The OCC model usually protects against another client overwriting and producing a new version of the data, but it can also help during failover where a client might encounter older versions of data. Let's imagine that you're using the timestamp as the version. The form was first built against Region A at 12:00 but (after failover) tries to write to Region B and notices that the latest version in the database is 11:59. In this scenario, the client can either wait for the 12:00 version to propagate to Region B and then write on top of that version, or build on 11:59 and create a new 12:01 version (which, after writing, would suppress the incoming version after Region A recovers).

As a third example, a financial services company holds data about customer accounts and their financial transactions in a DynamoDB database. In the event of a complete Region A outage, they want to make sure that any write activity related to their accounts is either fully available in Region B, or they want to quarantine their accounts as known partial until Region A comes back online. Instead of pausing all business, they decided to pause business only to the tiny fraction of accounts that they determined had unpropagated transactions. To achieve this, they used a third Region, referred to here as Region C. Before they processed any write operations in Region A, they placed a succinct summary of those pending operations (for example, a new transaction count for an account) in Region C. This summary was sufficient for Region B to determine if its view was fully up to date. This action effectively locked the account from the time of writing in Region C until Region A accepted the write operations and Region B received them. The data in Region C wasn't used except as part of a failover process, after which Region B could cross-check its data with Region C to check if any of its accounts were out of date. Those accounts would be marked as quarantined until the Region A recovery propagated the partial data to Region B. If Region C were to fail, a new Region D could be spun up for use instead. The data in Region C was very transient, and after a few minutes Region D would have a sufficiently up-to-date record of the in-flight write operations to be fully useful. If Region B were to fail, Region A could continue accepting write requests in cooperation with Region C. This company was willing to accept higher latency writes (to two Regions: C and then A) and

was fortunate to have a data model where the state of an account could be succinctly summarized.

the section called “Evacuation processes”, based on your consistency mode, write mode, and routing strategy.

- Capture metrics on the health, latency, and errors across each Region. For a list of DynamoDB metrics to observe, see Monitoring Amazon DynamoDB for Operational Awareness on the AWS Database Blog. You should also use synthetic canaries (artificial requests designed to detect failures, named after the canary in the coal mine), as well as live observation of customer traffic. Not all issues will appear in the DynamoDB metrics.
- If you're using MREC, set alarms for any sustained increase in `ReplicationLatency`. An increase might indicate an accidental misconfiguration in which the global table has different write settings in different Regions, which leads to failed replicated requests and increased latencies. It could also indicate that there is a Regional disruption. A good example is to generate an alert if the recent average exceeds 180,000 milliseconds. You might also watch for `ReplicationLatency` dropping to 0, which indicates stalled replication.
- Assign sufficient maximum read and write settings for each global table.
- Identify the reasons for evacuating a Region in advance. If the decision involves human judgment, document all considerations. This work should be done carefully in advance, not under stress.
- Maintain a runbook for every action that must take place when you evacuate a Region. Usually very little work is involved for the global tables, but moving the rest of the stack might be complex.

  > **Note**
  >
  > With failover procedures, it's best practice to rely only on data plane operations and not on control plane operations, because some control plane operations could be degraded during Region failures.

  For more information, see the AWS blog post Build resilient applications with Amazon DynamoDB global tables: Part 4.
- Test all aspects of the runbook periodically, including Region evacuations. An untested runbook is an unreliable runbook.

- Consider using AWS Resilience Hub to evaluate the resilience of your entire application (including global tables). It provides a comprehensive view of your overall application portfolio resilience status through its dashboard.
- Consider using ARC readiness checks to evaluate the current configuration of your application and track any deviances from best practices.
- When you write health checks for use with Route 53 or Global Accelerator, make a set of calls that cover the full database flow. If you limit your check to confirm only that the DynamoDB endpoint is up, you won't be able to cover many failure modes such as AWS Identity and Access Management (IAM) configuration errors, code deployment problems, failure in the stack outside DynamoDB, higher than average read or write latencies, and so on.

Frequently Asked Questions (FAQ) for deploying global tables

How does pricing for global tables work?

Global tables are priced based on the resources each replica consumes in its own Region, including replicated write units, storage, and reads. For a full breakdown of global tables pricing, see Pricing for global tables.

Which Regions does global tables support?

Global Tables version 2019.11.21 (Current) supports all AWS Regions for MREC tables.

MRSC global tables are available in the following AWS Regions: US East (N. Virginia), US East (Ohio), US West (Oregon), Canada (Central), Europe (Ireland), Europe (London), Europe (Paris), Europe (Frankfurt), Europe (Stockholm), Europe (Spain), Asia Pacific (Tokyo), Asia Pacific (Seoul), Asia Pacific (Osaka), Asia Pacific (Mumbai), and Asia Pacific (Singapore). An MRSC global table can include replicas from any combination of three of these Regions, including Regions on different continents.

How are GSIs handled with global tables?

In Global Tables version 2019.11.21 (Current), when you create a GSI in one Region it's automatically created in other participating Regions and automatically backfilled.

How do I stop replication of a global table?

- You can delete a replica table the same way you would delete any other table. Deleting the global table stops replication to that Region and deletes the table copy kept in that Region.

However, you can't stop replication while keeping copies of the table as independent entities, nor can you pause replication.

- An MRSC table must be deployed in exactly three Regions. To delete the replicas you must delete all the replicas and the witness so that the MRSC table becomes a local table.

How do DynamoDB Streams interact with global tables?

- Each global table produces an independent stream based on all its write operations, wherever they started from. You can choose to consume the DynamoDB stream in one Region or in all Regions (independently). If you want to process local but not replicated write operations, you can add your own Region attribute to each item to identify the writing Region. You can then use a Lambda event filter to call the Lambda function only for write operations in the local Region. This helps with insert and update operations, but not delete operations.
- Global tables that are configured for multi-Region eventual consistency (MREC tables) replicate changes by reading those changes from a DynamoDB stream on a replica table and applying that change to all other replica tables. Therefore, DynamoDB Streams is enabled by default on all replicas in an MREC global table and cannot be disabled on those replicas. The MREC replication process can combine multiple changes in a short period of time into a single replicated write operation. As a result, each replica's stream might contain slightly different records. DynamoDB Streams records on MREC replicas are always ordered on a per-item basis, but ordering between items might differ between replicas.
- Global tables that are configured for multi-Region strong consistency (MRSC tables) don’t use DynamoDB Streams for replication, so this feature isn’t enabled by default on MRSC replicas. You can enable DynamoDB Streams on an MRSC replica. DynamoDB Streams records on MRSC replicas are identical for every replica and are always ordered on a per-item basis, but ordering between items might differ between replicas.

How do global tables handle transactions?

- Transactional operations on MRSC tables will generate errors.
- Transactional operations on MREC tables provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the Region where the write operation originally occurred. Transactions are not supported across Regions in global tables. For example, if you have an MREC global table with replicas in the US East (Ohio) and US West (Oregon) Regions and perform a `TransactWriteItems` operation in the US East (Ohio) Region, you might observe partially

completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

How do global tables interact with the DynamoDB Accelerator cache (DAX)?

Global tables bypass DAX by updating DynamoDB directly, so DAX isn't aware that it's holding stale data. The DAX cache is refreshed only when the cache's TTL expires.

Do tags on tables propagate?

No, tags do not automatically propagate.

Should I backup tables in all Regions or just one?

The answer depends on the purpose of the backup.

- If you want to ensure data durability, DynamoDB already provides that safeguard. The service ensures durability.
- If you want to keep a snapshot for historical records (for example, to meet regulatory requirements), backing up in one Region should suffice. You can copy the backup to additional Regions by using AWS Backup.
- If you want to recover erroneously deleted or modified data, use DynamoDB point-in-time recovery (PITR) in one Region.

How do I deploy global tables using CloudFormation?

- CloudFormation represents a DynamoDB table and a global table as two separate resources: `AWS::DynamoDB::Table` and `AWS::DynamoDB::GlobalTable`. One approach is to create all tables that can potentially be global by using the `GlobalTable` construct of keeping them as standalone tables initially, and add Regions later if necessary.
- In CloudFormation, each global table is controlled by a single stack, in a single Region, regardless of the number of replicas. When you deploy your template, CloudFormation creates and updates all replicas as part of a single stack operation. You should not deploy the same AWS::DynamoDB::GlobalTable resource in multiple Regions. This will result in errors and is unsupported. If you deploy your application template in multiple Regions, you can use conditions to create the `AWS::DynamoDB::GlobalTable` resource in a single Region. Alternatively, you can choose to define your `AWS::DynamoDB::GlobalTable` resources in a stack that's separate from your application stack, and make sure that it's deployed to a single Region.

- If you have a regular table and you want to convert it to a global table while keeping it managed by CloudFormation then set the deletion policy to `Retain`, remove the table from the stack, convert the table to a global table in the console, and then import the global table as a new resource to the stack. For more information, see the AWS GitHub repository.
- You can use CloudFormation (and the AWS CDK) to configure multi-account (cross-account) global tables. For more information, see DynamoDB multi-account global tables.

Conclusion and resources

DynamoDB global tables have very few controls but still require careful consideration. You must determine your write mode, routing model, and evacuation processes. You must instrument your application across every Region and be ready to adjust your routing or perform an evacuation to maintain global health. The reward is having a globally distributed dataset with low-latency read and write operations that is designed for 99.999% availability.

Best practices for managing the control plane in DynamoDB

> **Note**
>
> DynamoDB is introducing a control plane throttle limit of 2,500 requests per second with the option for a retry. See below for additional details.

DynamoDB control plane operations let you manage DynamoDB tables as well as objects that are dependent on tables such as indexes. For more information about these operations, see Control plane.

In some circumstances, you might need to take actions and use data returned by control plane calls as part of your business logic. For example, you might need to know the value of `ProvisionedThroughput` returned by `DescribeTable`. In these circumstances, follow these best practices:

- Do not excessively query the DynamoDB control plane.
- Do not mix control plane calls and data plane calls within the same code.
- Handle throttles on control plane requests and retry with a backoff.
- Invoke and track changes to a particular resource from a single client.
- Instead of retrieving data for the same table multiple times at short intervals, cache the data for processing.

Best practices for using bulk data operations in DynamoDB

DynamoDB supports batch operations such as `BatchWriteItem` using which you can perform up to 25 `PutItem` and `DeleteItem` requests together. However, `BatchWriteItem` doesn't support `UpdateItem` operations. When it comes to bulk updates, the distinction lies in the requirements and the nature of the update. You can use other DynamoDB APIs such as `TransactWriteItems`

for batch size up to 100. When more items are involved, you can use services such as AWS Glue, Amazon EMR, AWS Step Functions, custom scripts and tools like DynamoDB-shell, or the open-source Bulk Executor for DynamoDB for bulk updates.

Topics

- Conditional batch update
- Efficient bulk operations

Conditional batch update

DynamoDB supports batch operations such as `BatchWriteItem` using which you can perform up to 25 `PutItem` and `DeleteItem` requests in a single batch. However, `BatchWriteItem` doesn't support `UpdateItem` operations and doesn't support condition expressions. As a workaround, you can use other DynamoDB APIs such as `TransactWriteItems` for batch size up to 100.

When more items are involved, and a major chunk of data needs to be changed, you can use services such as AWS Glue, Amazon EMR, AWS Step Functions or use custom scripts and tools like DynamoDB-shell for efficient bulk updates.

When to use this pattern

- DynamoDB-shell is not a supported for production use case.
- `TransactWriteItems` – up to 100 individual updates with or without conditions, executing as an all or nothing ACID bundle. `TransactWriteItems` calls can also be supplied with a `ClientRequestToken` if your application requires idempotency, meaning multiple identical calls have the same effect as one single call. This ensures you don't execute the same transaction multiple times and end up with an incorrect state of data.

  Trade-off – Additional throughput is consumed. 2 WCUs per 1KB write instead of the standard 1 WGU per 1 KB write.
- PartiQL `BatchExecuteStatement` – up to 25 updates with or without conditions. `BatchExecuteStatement` always returns a success response to the overall request, and also returns a list of individual operation responses that preserves order.

  Trade-off – For larger batches, additional client-side logic is required to distribute requests in batches of 25. Individual error responses need to be considered to determine retry strategy.

Code examples

These code examples use the boto3 library, which is the AWS SDK for Python. The examples assume you have boto3 installed and configured with appropriate AWS credentials.

Assume an inventory database for an electrical appliance vendor who has multiple warehouses across European cities. Because it is end of summer, the vendor would like to clear out desk fans to make room for other stock. The vendor wants to provide a price discount for all desk fans supplied out of warehouses in Italy but only if they have a reserve stock of 20 desk fans. The DynamoDB table is called **inventory**, it has a key schema of Partition key **sku** which is a unique identifier for each product and a Sort key **warehouse** which is an identifier for a warehouse.

The following Python code demonstrates how to perform this conditional batch update using `BatchExecuteStatement` API call.

```
import boto3

client=boto3.client("dynamodb")

before_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("Before update: ", before_image['Items'])

response=client.batch_execute_statement(
        Statements=[
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITTUR1'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITROM1'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITROM2'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITROM5'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITVEN1'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
```

```
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITVEN2'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITVEN3'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
        ],
        ReturnConsumedCapacity='TOTAL'
    )

after_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("After update: ", after_image['Items'])
```

Execution produces the below output on sample data:

```
Before update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price':
 {'N': '40'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S':
 'WITROM2'}, 'price': {'N': '40'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '28'}, 'warehouse': {'S': 'WITROM5'}, 'price': {'N': '38'}, 'sku': {'S': 'F123'}},
 {'quantity': {'N': '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '40'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price':
 {'N': '38'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S':
 'WITVEN2'}, 'price': {'N': '38'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'},
 'warehouse': {'S': 'WITVEN3'}, 'price': {'N': '35'}, 'sku': {'S': 'F123'}}]
After update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price': {'N':
 '40'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S': 'WITROM2'},
 'price': {'N': '35'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '28'}, 'warehouse':
 {'S': 'WITROM5'}, 'price': {'N': '33'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '35'}, 'sku': {'S': 'F123'}},
 {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price': {'N': '38'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S': 'WITVEN2'}, 'price':
 {'N': '38'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'}, 'warehouse': {'S':
 'WITVEN3'}, 'price': {'N': '30'}, 'sku': {'S': 'F123'}}]
```

Since this is a bounded operation for an internal system, idempotency requirements haven't been considered. It's possible to place additional guardrails like price update should go through only if price is greater than 35 and less than 40 to make the updates more robust.

Alternatively, you can perform the same batch update operation using `TransactWriteItems` in case of stricter idempotency and ACID requirements. However, it is important to remember that either all the operations in the transaction bundle go through or the entire bundle fails.

Let's assume a case where there is a heatwave in Italy and the demand for desk fans has increased sharply. The vendor wants to increase their desk fan cost going out of every warehouse in Italy by 20 Euros but the regulatory body only allows this cost increase if the current cost is less than 70 Euros across their entire inventory. It's essential that the price is updated throughout the inventory at once and only once and only if the cost is less than 70 Euros in each of their warehouse.

The following Python code demonstrates how to perform this batch update using `TransactWriteItems` API call.

```
import boto3

client=boto3.client("dynamodb")

before_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("Before update: ", before_image['Items'])

response=client.transact_write_items(
        ClientRequestToken='UUIDAWS124',
        TransactItems=[
            {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITTUR1'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
            {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITROM1'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
            {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITROM2'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
            {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITROM5'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
```

```
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITVEN1'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITVEN2'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITVEN3'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
       ],
       ReturnConsumedCapacity='TOTAL'
   )

after_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("After update: ", after_image['Items'])
```

Execution produces the below output on sample data:

```
Before update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price':
 {'N': '60'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S':
 'WITROM2'}, 'price': {'N': '55'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '28'}, 'warehouse': {'S': 'WITROM5'}, 'price': {'N': '53'}, 'sku': {'S': 'F123'}},
 {'quantity': {'N': '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '55'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price':
 {'N': '58'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S':
 'WITVEN2'}, 'price': {'N': '58'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'},
 'warehouse': {'S': 'WITVEN3'}, 'price': {'N': '50'}, 'sku': {'S': 'F123'}}]
After update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price': {'N':
 '80'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S': 'WITROM2'},
 'price': {'N': '75'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '28'}, 'warehouse':
 {'S': 'WITROM5'}, 'price': {'N': '73'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '75'}, 'sku': {'S': 'F123'}},
 {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price': {'N': '78'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S': 'WITVEN2'}, 'price':
```

```
{'N': '78'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'}, 'warehouse': {'S':
'WITVEN3'}, 'price': {'N': '70'}, 'sku': {'S': 'F123'}}]
```

There are multiple approaches to perform batch updates in DynamoDB. The suitable approach depends on factors such as ACID and/or idempotency requirements, number of items to be updated, and familiarity with APIs.

Efficient bulk operations

When to use this pattern

These patterns are useful to efficiently perform bulk updates on DynamoDB items.

- DynamoDB-shell is not a supported for production use case.
- `TransactWriteItems` – up to 100 individual updates with or without conditions, executing as an all or nothing ACID bundle

  Trade-off – Additional throughput is consumed, 2 WCUs per 1 KB write.
- PartiQL `BatchExecuteStatement` – up to 25 updates with or without conditions

  Trade-off – Additional logic is required to distribute requests in batches of 25.
- AWS Step Functions – rate-limited bulk operations for developers familiar with AWS Lambda.

  Trade-off – Execution time is inversely proportional to rate-limit. Limited by the maximum Lambda function timeout. The functionality entails that data changes that occur between the read and the write may be overwritten. For more info, see Backfilling an Amazon DynamoDB Time to Live attribute using Amazon EMR: Part 2.
- AWS Glue and Amazon EMR – rate-limited bulk operation with managed parallelism. For applications or updates that are not time-sensitive, these options can run in the background only consuming a small percentage of throughput. Both services uses the emr-dynamodb-connector to perform DynamoDB operations. These services perform a big read followed by a big write of updated items with an option to rate-limit.

  Trade-off – Execution time is inversely proportional to rate-limit. The functionality includes that data changes occurring between the read and the write can be overwritten. You can't read from Global Secondary Indexes (GSIs). See, Backfilling an Amazon DynamoDB Time to Live attribute using Amazon EMR: Part 2.
- DynamoDB Shell – rate-limited bulk operations using SQL-like queries. You can read from GSIs for better efficiency.

Trade-off – Execution time is inversely proportional to rate-limit. See Rate limited bulk operations in DynamoDB Shell.

- Bulk Executor for DynamoDB – an open-source command-line tool that uses AWS Glue on the back end for parallel execution of bulk tasks such as count, find, delete, update, copy, fill, load, and diff. No coding is required for built-in commands, and you can extend it with custom commands using Python. It supports rate-limiting and provides cost estimates before execution. Bulk Executor is open source and does not include any official support.

  Trade-off – Requires an AWS Glue environment (created during bootstrap). Execution time is inversely proportional to the rate limit. Custom commands require Python. See Introducing open source Bulk Executor for Amazon DynamoDB.

Using the pattern

Bulk updates can have significant cost implications especially if you use the on-demand throughput mode. There's a trade-off between speed and cost if you use the provisioned throughput mode. Setting the rate-limit parameter very strictly can lead to a very large processing time. You can roughly determine speed of the update using the average item size and the rate limit.

Alternatively, you can determine amount of throughput needed for the process based on the expected duration of the update process and the average item size. The blog references shared with each pattern provide details on the strategy, implementation and limitations of using the pattern. For more information, see Cost-effective bulk processing with Amazon DynamoDB.

There are multiple approaches to perform bulk-updates against a live DynamoDB table. The suitable approach depends on factors such as ACID and/or idempotency requirements, number of items to be updated and familiarity with APIs. It is important to consider the cost versus time trade-off, most approaches discussed above provide an option to rate-limit the throughput used by the bulk update job.

Best practices for handling concurrent updates in DynamoDB

In distributed systems, multiple processes or users might attempt to modify the same data at the same time. Without concurrency control, these concurrent writes can lead to lost updates, inconsistent data, or race conditions. DynamoDB provides several mechanisms to help you manage concurrent access and maintain data integrity.

> **Note**
>
> Individual write operations such as `UpdateItem` are atomic and always operate on the most recent version of the item, regardless of concurrency. Locking strategies are needed when your application must read an item and then write it back based on the read value (a read-modify-write cycle), because another process could modify the item between the read and the write.

There are two primary strategies for handling concurrent updates:

- **Optimistic locking** – Assumes conflicts are rare. It allows concurrent access and detects conflicts at write time using conditional writes. If a conflict is detected, the write fails and the application can retry.
- **Pessimistic locking** – Assumes conflicts are likely. It prevents concurrent access by acquiring exclusive access to a resource before modifying it. Other processes must wait until the lock is released.

The following table summarizes the approaches available in DynamoDB:

Approach	Mechanism	Best for
Optimistic locking	Version attribute + conditional writes	Low contention, inexpensive retries
Pessimistic locking (transactions)	`TransactWriteItems`	Multi-item atomicity, moderate contention
Pessimistic locking (lock client)	Dedicated lock table with lease and heartbeat	Long-running workflows, distributed coordination

Optimistic locking with version number

Optimistic locking is a strategy that detects conflicts at write time rather than preventing them. Each item includes a version attribute that increments with every update. When updating an item, you include a condition expression that checks whether the version number matches the value your

application last read. If another process modified the item in the meantime, the condition fails and DynamoDB returns a `ConditionalCheckFailedException`.

When to use optimistic locking

Optimistic locking is a good fit when:

- Multiple users or processes might update the same item, but conflicts are infrequent.
- Retrying a failed write is inexpensive for your application.
- You want to avoid the overhead and complexity of managing distributed locks.

Common examples include e-commerce inventory updates, collaborative editing platforms, and financial transaction records.

Tradeoffs

Retry overhead in high contention

In high-concurrency environments, the likelihood of conflicts increases, potentially causing higher retries and write costs.

Implementation complexity

Adding version control to items and handling conditional checks adds complexity to the application logic. The AWS SDK for Java v2 Enhanced Client provides built-in support through the `@DynamoDbVersionAttribute` annotation, which automatically manages version numbers for you.

Pattern design

Include a version attribute in each item. Here is a simple schema design:

- Partition key – A unique identifier for each item (for example, `ItemId`).
- Attributes:
  - `ItemId` – The unique identifier for the item.
  - `Version` – An integer that represents the version number of the item.
  - `QuantityLeft` – The remaining inventory of the item.

When an item is first created, the `Version` attribute is set to 1. With each update, the version number increments by 1.

ItemID (partition key)	Version	QuantityLeft
Bananas	1	10
Apples	1	5
Oranges	1	7

Implementation

To implement optimistic locking, follow these steps:

1. Read the current version of the item.

```
def get_item(item_id):
    response = table.get_item(Key={'ItemID': item_id})
    return response['Item']

item = get_item('Bananas')
current_version = item['Version']
```

2. Update the item using a condition expression that checks the version number.

```
def update_item(item_id, qty_bought, current_version):
    try:
        response = table.update_item(
            Key={'ItemID': item_id},
            UpdateExpression="SET QuantityLeft = QuantityLeft - :qty, Version
 = :new_v",
            ConditionExpression="Version = :expected_v",
            ExpressionAttributeValues={
                ':qty': qty_bought,
                ':new_v': current_version + 1,
                ':expected_v': current_version
            },
            ReturnValues="UPDATED_NEW"
        )
        return response
```

```
    except ClientError as e:
        if e.response['Error']['Code'] == 'ConditionalCheckFailedException':
            print("Version conflict: another process updated this item.")
        raise
```

3. Handle conflicts by retrying with a fresh read.

   Each retry requires an additional read, so limit the total number of retries.

```
def update_with_retry(item_id, qty_bought, max_retries=3):
    for attempt in range(max_retries):
        item = get_item(item_id)
        try:
            return update_item(item_id, qty_bought, item['Version'])
        except ClientError as e:
            if e.response['Error']['Code'] != 'ConditionalCheckFailedException':
                raise
            print(f"Retry {attempt + 1}/{max_retries}")
    raise Exception("Update failed after maximum retries.")
```

For Java applications, the AWS SDK for Java v2 Enhanced Client provides built-in optimistic locking support through the `@DynamoDbVersionAttribute` annotation, which automatically manages version numbers for you.

For more information about condition expressions, see DynamoDB condition expression CLI example.

Pessimistic locking with DynamoDB transactions

DynamoDB transactions provide an all-or-nothing approach to grouped operations. When you use `TransactWriteItems`, DynamoDB monitors all items in the transaction. If any item is modified by another operation during the transaction, the entire transaction is canceled and DynamoDB returns a `TransactionCanceledException`. This behavior provides a form of pessimistic concurrency control because conflicting concurrent modifications are prevented rather than detected after the fact.

When to use transactions for locking

Transactions are a good fit when:

- You need to update multiple items atomically, either within the same table or across tables.

- Your business logic requires all-or-nothing semantics – either all changes succeed or none are applied.

Common examples include transferring funds between accounts, placing orders that update both inventory and order tables, and exchanging items between players in a game.

Tradeoffs

Higher write cost

For items up to 1 KB, transactions consume 2 WCUs per item (one to prepare, one to commit), compared to 1 WCU for a standard write.

Item limit

A single transaction can include up to 100 actions across one or more tables.

Conflict sensitivity

If any item in the transaction is modified by another operation, the entire transaction fails. In high-contention scenarios, this can lead to frequent cancellations.

Implementation

The following example uses `TransactWriteItems` to transfer inventory between two items atomically. If another process modifies either item during the transaction, the entire operation is rolled back.

```
import boto3

client = boto3.client('dynamodb')

def transfer_inventory(source_id, target_id, quantity):
    try:
        client.transact_write_items(
            TransactItems=[
                {
                    'Update': {
                        'TableName': 'Inventory',
                        'Key': {'ItemID': {'S': source_id}},
                        'UpdateExpression': 'SET QuantityLeft = QuantityLeft - :qty',
                        'ConditionExpression': 'QuantityLeft >= :qty',
```

```
                    'ExpressionAttributeValues': {
                        ':qty': {'N': str(quantity)}
                    }
                }
            },
            {
                'Update': {
                    'TableName': 'Inventory',
                    'Key': {'ItemID': {'S': target_id}},
                    'UpdateExpression': 'SET QuantityLeft = QuantityLeft + :qty',
                    'ExpressionAttributeValues': {
                        ':qty': {'N': str(quantity)}
                    }
                }
            }
        ]
    )
    return True
except client.exceptions.TransactionCanceledException as e:
    print(f"Transaction canceled: {e}")
    return False
```

In this example, the condition expression checks that sufficient inventory exists, but no version attribute is needed. DynamoDB automatically cancels the transaction if any item in the transaction is modified by another operation between the prepare and commit phases. This is what provides the pessimistic concurrency control – conflicting concurrent modifications are prevented by the transaction itself.

> **Note**
>
> You can combine transactions with optimistic locking by adding version checks as additional condition expressions. This provides an extra layer of protection but is not required for the transaction to detect conflicts.

For more information, see Managing complex workflows with DynamoDB transactions.

Distributed locking with the DynamoDB Lock Client

For applications that require traditional lock-acquire-release semantics, the DynamoDB Lock Client is an open-source library that implements distributed locking using a DynamoDB table as the lock

store. This approach is useful when you need to coordinate access to an external resource (such as an S3 object or a shared configuration) across multiple application instances.

The lock client is available as an open-source Java library.

How it works

The lock client uses a dedicated DynamoDB table to track locks. Each lock is represented as an item with the following key attributes:

- A partition key that identifies the resource being locked.
- A lease duration that specifies how long the lock is valid. If the lock holder crashes or becomes unresponsive, the lock automatically expires after the lease duration.
- A heartbeat that the lock holder sends periodically to extend the lease. This prevents the lock from expiring while the holder is still actively processing.

The lock client uses conditional writes to make sure that only one process can acquire a lock at a time. If a lock is already held, the caller can choose to wait and retry or fail immediately.

When to use the lock client

The lock client is a good fit when:

- You need to coordinate access to a shared resource across multiple application instances or microservices.
- The critical section is long-running (seconds to minutes) and retrying the entire operation on conflict would be expensive.
- You need automatic lock expiry to handle process failures gracefully.

Common examples include orchestrating distributed workflows, coordinating cron jobs across multiple instances, and managing access to shared external resources.

Tradeoffs

Additional infrastructure

Requires a dedicated DynamoDB table for lock management, with additional read and write capacity for lock operations and heartbeats.

Clock dependency

Lock expiry relies on timestamps. Significant clock skew between clients can cause unexpected behavior, particularly for short lease durations.

Deadlock risk

If your application acquires locks on multiple resources, you must acquire them in a consistent order to avoid deadlocks. The lease duration provides a safety net by automatically releasing locks from unresponsive holders.

Implementation

The following example shows how to use the DynamoDB Lock Client to acquire and release a lock:

```
import java.io.IOException;
import java.util.Optional;
import java.util.concurrent.TimeUnit;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;

final DynamoDbClient dynamoDB = DynamoDbClient.builder()
    .region(Region.US_WEST_2)
    .build();

final AmazonDynamoDBLockClient lockClient = new AmazonDynamoDBLockClient(
    AmazonDynamoDBLockClientOptions.builder(dynamoDB, "Locks")
        .withTimeUnit(TimeUnit.SECONDS)
        .withLeaseDuration(10L)
        .withHeartbeatPeriod(3L)
        .withCreateHeartbeatBackgroundThread(true)
        .build());

// Try to acquire a lock on a resource
final Optional<LockItem> lock =
    lockClient.tryAcquireLock(AcquireLockOptions.builder("my-shared-
resource").build());

if (lock.isPresent()) {
    try {
        // Perform operations that require exclusive access
        processSharedResource();
    } finally {
        // Always release the lock when done
```

```
        lockClient.releaseLock(lock.get());
    }
} else {
    System.out.println("Failed to acquire lock.");
}

lockClient.close();
```

> **Important**
>
> Always release locks in a `finally` block to make sure locks are released even if your processing logic throws an exception. Unreleased locks block other processes until the lease expires.

You can also implement a simple locking mechanism without the lock client library by using conditional writes directly. The following example uses `UpdateItem` with a condition expression to acquire a lock, and `DeleteItem` to release it:

```
from datetime import datetime, timedelta
from boto3.dynamodb.conditions import Attr

def acquire_lock(table, resource_name, owner_id, ttl_seconds):
    """Attempt to acquire a lock. Returns True if successful."""
    expiry = (datetime.now() + timedelta(seconds=ttl_seconds)).isoformat()
    now = datetime.now().isoformat()
    try:
        table.update_item(
            Key={'LockID': resource_name},
            UpdateExpression='SET #owner = :owner, #expiry = :expiry',
            ConditionExpression=Attr('LockID').not_exists() |
 Attr('ExpiresAt').lt(now),
            ExpressionAttributeNames={'#owner': 'OwnerID', '#expiry': 'ExpiresAt'},
            ExpressionAttributeValues={':owner': owner_id, ':expiry': expiry}
        )
        return True
    except table.meta.client.exceptions.ConditionalCheckFailedException:
        return False

def release_lock(table, resource_name, owner_id):
    """Release a lock. Only succeeds if the caller is the lock owner."""
    try:
```

```
        table.delete_item(
            Key={'LockID': resource_name},
            ConditionExpression=Attr('OwnerID').eq(owner_id)
        )
        return True
    except table.meta.client.exceptions.ConditionalCheckFailedException:
        return False
```

This approach uses a condition expression to make sure that a lock can only be acquired if it doesn't exist or has expired, and can only be released by the process that acquired it. Consider enabling Time to Live (TTL) on the lock table to automatically clean up expired lock items.

Choosing a concurrency control strategy

Use the following guidelines to choose the right approach for your workload:

Use optimistic locking when:

- Conflicts are infrequent.
- Retrying a failed write is inexpensive.
- You are updating a single item at a time.

Use transactions when:

- You need to update multiple items atomically.
- You require all-or-nothing semantics across items or tables.
- You need to combine condition checks with writes in a single operation.

Use the lock client when:

- You need to coordinate access to external resources across distributed processes.
- The critical section is long-running and retrying on conflict is expensive.
- You need automatic lock expiry to handle process failures.

> **Note**
>
> If you use DynamoDB global tables, be aware that global tables use a "last writer wins" reconciliation strategy for concurrent updates. Optimistic locking with version numbers does not work as expected across Regions because a write in one Region might overwrite

a concurrent write in another Region without a version check. Design your application to handle conflicts at the application level when using global tables.

Best practices for understanding your AWS billing and usage reports in DynamoDB

This document explains the `UsageType` billing codes for charges related to DynamoDB.

AWS provides cost and usage reports (CUR) that contain data for the services used. You can use AWS Cost and Usage Report to publish billing reports to Amazon S3 in a CSV format. When setting up the CUR you can choose to break time periods down by hour, day, or month, and you can choose if you want to break out usage by resource ID or not. For more information about generating CUR, see Creating Cost and Usage Reports in the AWS Data Exports User Guide.

Within the CSV export, you will find relevant attributes listed for each line. The following are examples of attributes that might be included:

- **lineitem/UsageStartDate:** The start date and time for the line item in UTC, inclusive.
- **lineitem/UsageEndDate:** The end date and time for the corresponding line item in UTC, exclusive.
- **lineitem/ProductCode:** For DynamoDB this will be “AmazonDynamoDB”
- **lineitem/UsageType:** A specific description code for the type of usage, as enumerated in this document
- **lineitem/Operation:** A name that provides context to the charge such as the operation name that incurred the charge (optional).
- **lineitem/ResourceId:** The identifier for the resource that incurred the usage. Available if the CUR includes a breakdown by resource ID.
- **lineitem/UsageAmount:** The amount of usage incurred during the specified time period.
- **lineitem/UnblendedCost:** The cost of this usage.
- **lineitem/LineItemDescription:** Textual description of the line item.

For more information about the CUR data dictionary, see Cost and Usage Report (CUR) 2.0 in the AWS Data Exports User Guide. Note that the exact names vary depending on context.

A `UsageType` is a string with a value such as `ReadCapacityUnit-Hrs`, `USW2-ReadRequestUnits`, `EU-WriteCapacityUnit-Hrs`, or `USE1-TimedPITRStorage-ByteHrs`. Each usage type begins with an optional Region prefix. If absent, that indicates the us-east-1 Region. If present, the below table maps the short billing Region code to the conventional Region code and name.

For example, the usage named `USW2-ReadRequestUnits` indicates read request units consumed in us-west-2.

Billing Region Code	Region Code	Region Name
AFS1	af-south-1	Africa (Cape Town)
APE1	ap-east-1	Asia Pacific (Hong Kong)
APN1	ap-northeast-1	Asia Pacific (Tokyo)
APN2	ap-northeast-2	Asia Pacific (Seoul)
APN3	ap-northeast-3	Asia Pacific (Osaka)
APS1	ap-southeast-1	Asia Pacific (Singapore)
APS2	ap-southeast-2	Asia Pacific (Sydney)
APS3	ap-south-1	Asia Pacific (Mumbai)
APS4	ap-southeast-3	Asia Pacific (Jakarta)
APS5	ap-south-2	Asia Pacific (Hyderabad)
APS6	ap-southeast-4	Asia Pacific (Melbourne)
CAN1	ca-central-1	Canada (Central)
EU	eu-west-1	Europe (Ireland)
EUC1	eu-central-1	Europe (Frankfurt)
EUC2	eu-central-2	Europe (Zurich)

Billing Region Code	Region Code	Region Name
EUN1	eu-north-1	Europe (Stockholm)
EUS1	eu-south-1	Europe (Milan)
EUS2	eu-south-2	Europe (Spain)
EUW1	eu-west-1	Europe (Ireland)
EUW2	eu-west-2	Europe (London)
EUW3	eu-west-3	Europe (Paris)
ILC1	Il-central-1	Israel (Tel Aviv)
MEC1	me-central-1	Middle East (UAE)
MES1	me-south-1	Middle East (Bahrain)
SAE1	sa-east-1	South America (São Paulo)
USE1 (default)	us-east-1	US East (N. Virginia)
USE2	us-east-2	US East (Ohio)
UGE1	us-gov-east-1	US Government East
UGW1	us-gov-west-1	US Government West
USW1	us-west-1	US West (N. California)
USW2	us-west-2	US West (Oregon)

The following sections use the `REG-UsageType` pattern when going through the charges for DynamoDB, where REG specifies the region where usage occurred and usageType is the code for the type of charge. For example if you see a line item for `USW1- ReadCapacityUnit-Hrs` in your CSV file, that means the usage was incurred in US-West-1 for provisioned read capacity. In that case the listing would say `REG-ReadCapacityUnit-Hrs`.

Throughput Capacity

Provisioned Capacity Reads and Writes

When you create a DynamoDB table in provisioned capacity mode, you specify the read and write capacity that you expect your application to require. The usage type depends on your table class (Standard or Standard-Infrequent Access). You provision read and writes based on consumption rate per second, but the charges are priced per hour based on provisioned capacity.

UsageType	Units	Granularity	Description
REG-ReadCapacityUnit-Hrs	RCU-hours	Hour	Charges for reads in provisioned capacity mode using the Standard table class.
REG-IA-ReadCapacityUnit-Hrs	RCU-hours	Hour	Charges for reads in provisioned capacity mode using the Standard-IA table class.
REG-WriteCapacityUnit-Hrs	WCU-hours	Hour	Charges for writes in provisioned capacity mode using the Standard table class.
REG-IA-WriteCapacityUnit-Hrs	WCU-hours	Hour	Charges for writes in provisioned capacity

UsageType	Units	Granularity	Description
			mode using the Standard-IA table class.

Reserved Capacity Reads and Writes

With reserved capacity, you pay a one-time upfront fee and commit to a minimum provisioned usage level over a period of time. Reserved capacity is billed at a discounted hourly rate. Any capacity that you provision in excess of your reserved capacity is billed at standard provisioned capacity rates. Reserved capacity is available for single-region, provisioned read and write capacity units (RCU and WCU) on DynamoDB tables that use the standard table class. Both 1-year and 3-year reserved capacity are billed using the same SKUs.

UsageType	Units	Granularity	Description
REG-HeavyUsage:dynamodb.read	RCU-hours	Up-front then monthly	Charges for reserved capacity reads: a one-time up-front charge and a monthly charge at the start of each month covering all the discounted committed RCU-hours during the month. Will have matching zero-cost REG-ReadCapacityUnit-Hrs line items.
REG-HeavyUsage:dynamodb.write	WCU-hours	Up-front then monthly	Charges for reserved capacity writes: a one-time up-front charge and a monthly charge at the start of each month covering

UsageType	Units	Granularity	Description
			all the discounted committed WCU-hours during the month. Will have matching zero-cost REG-WriteCapacityUnit-Hrs line items.

On-Demand Capacity Reads and Writes

When you create a DynamoDB table in on-demand capacity mode, you pay only for the reads and writes your application performs. The prices for read and write requests depend on your table class.

UsageType	Units	Granularity	Description
REG-ReadRequestUnits	RRUs	Unit	Charges for reads in on-demand capacity mode with Standard table class.
REG-IA-ReadRequestUnits	RRUs	Unit	Charges for reads in on-demand capacity mode with Standard-IA table class.
REG-WriteRequestUnits	WRUs	Unit	Charges for writes in on-demand capacity mode with Standard table class.
REG-IA-WriteRequestUnits	WRUs	Unit	Charges for writes in on-demand capacity mode with Standard-IA table class.

Global Tables Reads and Writes

DynamoDB charges for global tables usage based on the resources used on each replica table. For provisioned global tables, write requests for global tables are measured in replicated WCUs (rWCU) instead of standard WCUs and writes to global secondary indexes in global tables are measured in WCUs. For on-demand global tables, write requests are measured in replicated WRUs (rWRU) instead of standard WRUs. The number of rWCUs or rWRUs consumed for replication depends on the version of global tables you are using. The pricing depends on your table class.

Writes to global secondary indexes (GSIs) are billed using standard write units (WCUs and WRUs). Read requests and data storage are billed identically to single-region tables.

If you add a table replica to create or extend a global table in new Regions, DynamoDB charges for a table restore in the added Regions per gigabyte of data restored. Restored Data is charged as REG-RestoreDataSize-Bytes. Please refer to Backup and restore for DynamoDB for details. DynamoDB does not charge cross-Region data transfer fees for replicating data between the Regions of a global table.

When you select on-demand capacity mode for your DynamoDB global tables, you pay only for the resources your application uses on each replica table.

UsageType	Units	Granularity	Description
REG-ReplWriteCapacityUnit-Hrs	rWCU-hours	Hour	Global table, provisioned, Standard table class.
REG-IA-ReplWriteCapacityUnit-Hrs	rWCU-hours	Hour	Global table, provisioned, Standard-IA table class.
REG-ReplWriteRequestUnits	rWRU	Unit	Global table, on-demand, Standard table class.
REG-IA-ReplWriteRequestUnits	rWRU	Unit	Global table, on-demand, Standard- IA table class

Streams

DynamoDB has two streaming technologies, DynamoDB Streams and Kinesis. Each have separate pricing.

DynamoDB Streams charges for reading data in read request units. Each `GetRecords` API call is billed as a streams read request. You are not charged for `GetRecords` API calls invoked by AWS Lambda as part of DynamoDB triggers or by DynamoDB global tables as part of replication.

UsageType	Units	Granularity	Description
REG-Streams-RequestsCount	Count	Unit	Read request units for DynamoDB Streams.

Amazon Kinesis Data Streams charges in change data capture units. DynamoDB charges one change data capture unit for each write (up to 1 KB). For items larger than 1 KB, additional change data capture units are required. You pay only for the writes your application performs without having to manage throughput capacity on the table.

UsageType	Units	Granularity	Description
REG-ChangeDataCaptureUnits-Kinesis	CDC Units	Unit	Change data capture units for Kinesis Data Streams.

Storage

DynamoDB measures the size of your billable data by adding the raw byte size of your data plus a per-item storage overhead that depends on the features you have enabled.

> **Note**
>
> Storage usage values in the CUR will be higher compared with the storage values when using `DescribeTable`, because `DescribeTable` does not include the per-item storage overhead.

Storage is calculated hourly but priced monthly as calculated from an average of the hourly charges.

Although the storage `UsageType` uses `ByteHrs` as a suffix, storage usage in the CUR is measured in GB and priced by GB-month.

UsageType	Units	Granularity	Description
REG-TimedStorage-ByteHrs	GB	Month	Amount of storage used by your DynamoDB tables and indexes, for tables with the Standard table class.
REG-IA-TimedStorage- ByteHrs	GB	Month	Amount of storage used by your DynamoDB tables and indexes, for tables with the Standard-IA table class.

Backup and Restore

DynamoDB offers two types of backups: Point In Time Recovery (PITR) backups and on- demand backups. Users can also restore from those backups into DynamoDB tables. The charges below refers to both backups and restores.

Backup storage charges are incurred on the first of the month with adjustments made throughout the month as backups are added or removed. See the Understanding Amazon DynamoDB On-demand Backups and Billing blog for more information

UsageType	Units	Granularity	Description
REG-TimedBackupStorage-ByteHrs	GB	Month	The storage consumed by on-

UsageType	Units	Granularity	Description
			demand backups of your DynamoDB tables and Local Secondary Indexes.
TimedPITRStorage-ByteHrs	GB	Month	The storage used by point-in-time recovery (PITR) backups. DynamoDB monitors the size of your PITR-enabled tables continuously throughout the month to determine your backup charges and bills for storage as long as PITR is enabled.
REG-RestoreDataSize-Bytes	GB	Size	The total size of data restored (including table data, local secondary indexes and global secondary indexes) measured in GB from DynamoDB backups.

AWS Backup

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud as well as on premises. AWS Backup is charged for storage (warm or cold storage), restoration activities, and cross-Region data transfer. The following UsageType charges appear under the “AWSBackup” ProductCode rather than “AmazonDynamoDB”.

UsageType	Units	Granularity	Description
REG-WarmStorage-ByteHrs-DynamoDB	GB	Month	The storage used by DynamoDB backups managed by AWS Backup throughout the month, measured in GB-Month.
REG-CrossRegion-WarmBytes-DynamoDB	GB	Size	The data transferred to a different AWS Region either within the same account or to a different AWS account. Cross-Region transfers charges occur when copying backups from one Region to another Region. The charge is always billed to the account where the data is transferred from.
REG-Restore-WarmBytes-DynamoDB	GB	Size	The total size of the data restored from warm storage, measured in GB.
REG-ColdStorage-ByteHrs-DynamoDB	GB	Month	The cold storage used by DynamoDB backups managed by AWS Backup throughout the month, measured in GB-Month.

UsageType	Units	Granularity	Description
REG-Restore-ColdBytes-DynamoDB	GB	Month	The total size of the data restored from cold storage, measured in GB.

Export and Import

You can export data from DynamoDB to Amazon S3 or import data from Amazon S3 to a new DynamoDB table.

Although the `UsageType` uses `Bytes` as a suffix, export and import usage in the CUR is measured and priced in GB.

UsageType	Units	Granularity	Description
REG-ExportDataSize-Bytes	GB	Size	The charge for exporting data to S3. DynamoDB charges for data you export based on the size of the DynamoDB base table (table data and local secondary indexes) at the specified point in time when the export was created.
REG-ImportDataSize-Bytes	GB	Size	The charge for importing data from S3. The size is calculated based on the uncompressed object size of the data within Amazon

UsageType	Units	Granularity	Description
			S3. There are no extra charges for importing to tables with GSIs.
REG-IncrementalExportDataSize-Bytes	GB	Size	The charge for size of the data processed from the continuous backup to produce incremental exports.

Data Transfer

Data transfer activity might appear associated with the DynamoDB service. DynamoDB does not charge for inbound data transfer, and it does not charge for data transferred between DynamoDB and other AWS services within the same AWS Region (in other words, $0.00 per GB). Data transferred across AWS Regions (such as between DynamoDB in the US East [N. Virginia] Region and Amazon EC2 in the EU [Ireland] Region) is charged on both sides of the transfer.

UsageType	Units	Granularity	Description
REG-DataTransfer-In-Bytes	GB	Units	Data transferred in to DynamoDB from the internet.
REG-DataTransfer-Out-Bytes	GB	Units	Data transferred out from DynamoDB to the internet.

CloudWatch Contributor Insights

CloudWatch Contributor Insights for DynamoDB is a diagnostic tool for identifying the most frequently accessed and throttled keys in your DynamoDB table. The following `UsageType` charges appear under the “AmazonCloudWatch” ProductCode rather than “AmazonDynamoDB”.

UsageType	Units	Granularity	Description
REG-CW:ContributorEventsManaged	Events processed	Units	The amount of DynamoDB events processed. For example for a table with CloudWatch Contributor Insights enabled, anytime an item is read or written, it's counted as one event. If the table has a sort key, it results in charges for two events.
REG-CW:ContributorRulesManaged	Rule count	Month	DynamoDB creates rules to identify most accessed items and most throttled keys when you enable Cloud Watch Contributor Insights. This charge is incurred for the rules added for each entity (tables and GSIs) configured for logging CloudWatch contributor insights.

DynamoDB Accelerator (DAX)

DynamoDB Accelerator (DAX) is billed by the hour based on the instance type selected for the service. The charges below refers to the DynamoDB Accelerator instances provisioned.

The following UsageType charges appear under the “AmazonDAX” ProductCode rather than “AmazonDynamoDB”.

UsageType	Units	Granularity	Description
REG-NodeUsage:dax-<INSTANCETYPE>	Node-hour	Hour	The hourly usage of a particular instance type. Pricing is per node-hour consumed, from the time a node is launched until it is terminated. Each partial node-hour consumed will be billed as a full hour. DAX charges for each node in a DAX cluster. If you have a cluster with multiple nodes, you would see multiple line items in your billing report.

The instance type will be one of the values from the following list. For details about node types, see Nodes.

- r3.2xlarge, r4.8xlarge, or r5.8xlarge
- r3.4xlarge, r4.large, or r5.large
- r3.8xlarge, r4.xlarge, or r5.xlarge
- r3.2xlarge, r5.12xlarge, or t2.medium
- r3.4xlarge, r4.large, or r5.large
- r3.xlarge, r5.16xlarge, or t2.small
- r4.16xlarge, r5.24xlarge, or t3.medium
- r4.2xlarge, r5.2xlarge, or t3.small
- r4.4xlarge or r5.4xlarge

Migrating a DynamoDB table from one account to another

You can migrate an Amazon DynamoDB table from one account to another to implement a multi-account strategy or a backup strategy. You can also do it for testing, debugging, or compliance reasons. A common use case is copying DynamoDB tables across production, staging, test, and development environments where each environment utilizes a different AWS account.

DynamoDB offers two options for migrating tables from one AWS account to another:

- **AWS Backup for Cross-Account Backup and Restore:** AWS Backup is a fully managed backup service that enables you to centrally manage backups across multiple AWS services. With its cross-account backup and restore functionality, you can back up a DynamoDB table in one account and restore the backup to another account in the same AWS Organization.
- **DynamoDB Export and Import to Amazon S3:** Using the DynamoDB Export and Import to Amazon S3 features allows you to do a full export to an Amazon S3 bucket and then import that data into a new table in another AWS account. This approach is suitable when you need to migrate between accounts that are not part of the same AWS Organization or if you do not want to use AWS Backup.

> **Note**
>
> Import from Amazon S3 does not support tables with Local Secondary Indexes (LSIs), but it does support Global Secondary Indexes (GSIs). For more information on LSIs and GSIs, see Improving data access with secondary indexes in DynamoDB.

Migrate a table using AWS Backup for cross-account backup and restore

Prerequisites

- Source and target AWS accounts must belong to the same organization in the AWS Organizations service

- Valid AWS Identity and Access Management (IAM) permissions to create and use AWS Backup vaults

For more information about setting up cross-account backups, see Creating backup copies across AWS accounts.

Pricing information

AWS charges for the backup (based on the table size), any data copying between AWS Regions (based on the amount of data), for the restore (based on the amount of data), and for any ongoing storage charges. To avoid ongoing charges, you can delete the backup if you don't need it after the restore.

For more information about pricing, see AWS Backup pricing .

Step 1: Enable advanced features for DynamoDB and cross-account backup

1. In both the source and target AWS account, access the AWS Management Console and open the AWS Backup console.
2. Choose the **Settings** option.
3. Under **Advanced features for Amazon DynamoDB backups**, confirm that **Advanced features** is enabled. If it isn't, choose **Enable**.
4. Under **Cross-account management**, for **Cross-account backup**, choose **Turn On**.

Step 2: Create a backup vault in the source account and target account

1. In the source AWS accounts, open the AWS Backup console.
2. Choose **Backup vaults**.
3. Choose **Create Backup vault**.
4. Copy and save the **Amazon Resource Name (ARN)** of the created backup vaults and the target AWS account.
5. You'll need the ARNs of both the source and target backup vaults when copying the DynamoDB table backup between accounts.

Step 3: Create a DynamoDB table backup in the source account

1. On the **AWS Backup Dashboard page**, choose **Create on-demand backup**.
2. In the **Settings** section, select **DynamoDB** as the **Resource type**, and then select the table name.
3. In the **Backup vault** dropdown list, select the backup vault you created in the source account.
4. Select the desired **Retention period**.
5. Choose **Create on-demand backup**.
6. Monitor the status of the backup job on the **Backup Jobs** tab of the **AWS Backup Jobs** page.

Step 4: Copy the DynamoDB table backup from the source account to the target account

1. After the backup job completes, open the AWS Backup console in the source account and choose **Backup vaults**.
2. Under **Backups**, choose the DynamoDB table backup. Choose **Actions** and then **Copy**.
3. Enter the AWS Region of the target account.
4. For **External vault ARN**, enter the ARN of the backup vault you created in the target account.
5. In the target account backup vault, enable access from a source account to allow copying backups.

Step 5: Restore the DynamoDB table backup in the target account

1. In the target AWS account, open the AWS Backup console and choose **Backup vaults**
2. Under **Backups**, select the backup you copied from the source account. Choose **Actions**, then **Restore**.
3. Enter the name for the new DynamoDB table, the encryption that this new table will have, the key you want the restore to be encrypted with, and any other options.
4. When the restore is completed, the table status will show as **Active**.

Migrate a table using export to S3 and import from S3

Prerequisites

- You must enable Point-in-Time Recovery (PITR) for your table in order to perform the export to S3. For more information, see Enable point-in-time recovery in DynamoDB.
- Valid IAM permissions to perform the export. For more information, see Requesting a table export in DynamoDB.
- Valid IAM permissions sufficient to perform the import. For more information, see Requesting a table import in DynamoDB.

Pricing information

AWS charges for PITR (based on the size of the table and how long PITR is enabled for). If you don't need PITR except for the export, you can turn it off after the export concludes. AWS also charges for requests made against S3, for storing the exported data in S3 and for importing (based on the uncompressed size of the imported data).

For more information about DynamoDB pricing, see DynamoDB pricing.

> **Note**
>
> There are limits on the size and number of objects when importing from S3 to DynamoDB. For more information, see Import quotas.

Requesting a table export to Amazon S3

1. Sign in to the AWS Management Console and open the DynamoDB console.
2. In the navigation pane on the left side of the console, choose **Exports to S3**.
3. Choose a source table and destination S3 bucket. Enter the URL of the destination account bucket using the `s3://bucketname/prefix` format. `/prefix` is an optional folder to help keep your destination bucket organized.
4. Choose **Full export**. A full export outputs the full table snapshot of your table, at the point in time you specify.
   a. Select **Current time** to export the latest full table snapshot.
   b. For **Exported file format**, choose between DynamoDB JSON and Amazon Ion. The default option is DynamoDB JSON.
5. Choose **Export** to begin the export.

6. Small table exports should complete in a few minutes, but tables in the terabyte range can take more than an hour.

Requesting a table import from Amazon S3

1. Sign in to the AWS Management Console and open the DynamoDB console.
2. In the navigation pane on the left side of the console, choose **Import from S3**.
3. On the page that appears, select **Import from S3**.
4. Enter the Amazon S3 source URL. You can also find it by using the **Browse S3** button. The expected path is of the format `s3://bucket/prefix/AWSDynamoDB/<XXXXXXXX-XXXXXX>/data/`.
5. Specify if you are the S3 bucket owner.
6. Under **Import file compression**, select **GZIP** to match the export.
7. Under **Import file format**, select **DynamoDB JSON** to match the export.
8. Select **Next**. For **Specify table details**, choose the options for the new table that will be created to store your data.
9. Select **Next**. For **Configure table settings**, customize any additional table settings if applicable.
10. Select **Next** again to review your import options, then choose **Import** to begin the import task. You see your new table listed under **Imports from S3** with the status **Importing**. You cannot access your table during this time. Small imports should complete in a few minutes, but tables in the terabyte range can take more than an hour.
11. After the import completes, the status shows as **Active**, and you can start using the table.

Keeping tables in sync during migration

If you can pause write operations on the source table for the duration of the migration, then the source and output should match up exactly after the migration. If you can't pause write operations, the target table would normally be a bit behind the source after the migration. To catch up the source table, you can use streaming (DynamoDB Streams or Kinesis Data Streams for DynamoDB) to replay the writes that happened in the source table since the backup or export.

You should start reading the stream records prior to the timestamp when you exported the source table to S3. For example, if the export to S3 occurred at 2:00 PM and the import to the target table was concluded at 11:00 PM, you should initiate the DynamoDB stream reading at 1:58 PM.

The streaming options for change data capture table summarizes the features of each streaming model.

Using DynamoDB Streams with Lambda offers a streamlined approach for synchronizing data between the source and target DynamoDB tables. You can use a Lambda function to replay each write in the target table.

> **Note**
>
> Items are kept in the DynamoDB Streams for 24 hours, so you should plan to complete your backup and restore or export and import within that window.

Prescriptive guidance to integrate DAX with DynamoDB applications

DynamoDB Accelerator (DAX), is a DynamoDB-compatible caching service that provides fast in-memory performance for demanding applications, such as read-heavy applications. Using DAX, you can achieve response times in microseconds for accessing frequently requested data. This DynamoDB Accelerator prescriptive guide provides comprehensive insights and best practices for integrating DAX with your DynamoDB applications.

This guide provides foundational knowledge for those who are new to DAX or want to optimize their existing configurations. This guide covers various topics, for example, when to use DAX and creating a DAX cluster. It also includes practical examples and detailed explanations to help you effectively implement DAX in your projects. Finally, this guide offers advanced strategies that you need to implement to maximize DAX caching capabilities for ensuring fast and scalable applications.

Topics

- Evaluating the suitability of DAX for your use cases
- Configuring your DAX client
- Configuring your DAX cluster
- Sizing your DAX cluster
- Deploying a cluster
- Managing cluster operations

- Monitoring DAX

Evaluating the suitability of DAX for your use cases

This section explains when and why to use DAX. Using this guidance helps you to determine if integrating DAX with DynamoDB is advantageous for your application's workload patterns, performance requirements, and data consistency needs. It also covers scenarios where DAX might not be suitable, for example, write-heavy workloads and infrequently accessed data.

In this section

- When and why to choose DAX
- When not to use DAX

When and why to choose DAX

You can consider adding DAX to your application stack in several scenarios. For example, use DAX to reduce the overall latency of read requests against DynamoDB or to minimize repeated reads of the same data from a table. The following list presents examples of scenarios in which you can take advantage of integrating DAX with DynamoDB:

- **High-performance requirement**
  - **Low latency reads** – You should consider using DAX if your application requires response times in microseconds for eventually-consistent reads. DAX can also drastically reduce the response time for accessing frequently read data.
- **Read-intensive workloads**
  - **Read-heavy applications** – For applications with a high read-to-write ratio, for example, 10:1 or more, DAX results in more cache hits and less stale data. This reduces reads against a table. To avoid reading stale data from the cache if your application is write-heavy, make sure to set a lower Using time to live (TTL) in DynamoDB for the cache.
  - **Caching common queries** – If your application frequently reads the same data, for example, popular products on an e-commerce platform, DAX can serve these requests directly from its cache.
- **Bursty traffic patterns**

  - **Smoother table scaling** – DAX helps smooth out impacts of sudden traffic spikes. DAX provides a buffer to scale up DynamoDB table capacity gracefully, which reduces the risk of read throttling.
  - **Higher read throughput for each item** – DynamoDB allocates individual partitions for each item. However, a partition starts throttling reads of an item when it reaches 3,000 read capacity units (RCU). DAX lets you scale reads of a single item beyond 3,000 RCU.
- **Cost optimization**
  - **Reducing DynamoDB costs** – Reading from DAX can reduce reads sent to a DynamoDB table, which can then directly impact cost. With a high cache hit rate, the reduced table read cost can exceed a DAX cluster cost, which results in a net cost reduction.
- **Data consistency requirements**
  - **Eventual consistency** – DAX supports eventually consistent reads. This makes DAX suitable for use cases where immediate consistency isn't critical.
  - **Write-through caching** – Writes that you make against DAX are write-through. Once DAX confirms that it's written an item to DynamoDB, it persists that item version in the item cache. This write-through mechanism helps maintain tighter data consistency between cache and database, but uses additional DAX cluster resources.

When not to use DAX

While DAX is powerful, it's not suitable for all scenarios. The following list presents examples of scenarios in which integrating DAX with DynamoDB is unsuitable:

- **Write-heavy workloads** – The primary advantage of DAX is speeding up reads, but writes use more DAX resources than reads. If your application is predominantly write-heavy, DAX benefits might be limited.
- **Infrequently read data** – If your application accesses data infrequently or a wide range of rarely reused data (cold data), you'll likely experience a low cache hit ratio. In this case, the overhead of maintaining the cache might not justify the performance gains.
- **Bulk reads or writes** – If your application performs more bulk writes than individual writes, you should write around DAX. In addition, for bulk reads, you should run full table scans directly against a DynamoDB table.
- **Strong consistency or transaction requirements** – DAX passes strongly consistent reads and TransactGetItems calls to a DynamoDB table. You should make these reads around the DAX

cluster to avoid using cluster resources. Items read this way won't be cached; therefore, routing such items through DAX serves no purpose.

- **Simple applications with modest performance requirements** – For applications with modest performance requirements and tolerance for direct DynamoDB latency, the complexity and cost of adding DAX might not be necessary. On its own, DynamoDB handles high throughput and provides single-digit millisecond performance.
- **Complex querying needs beyond key-value access** – DAX is optimized for key-value access patterns. If your application requires complex querying capabilities with complex filtering, such as Query and Scan operations, DAX caching benefits might be limited.

  In these situations, use Amazon ElastiCache (Redis OSS) as an alternative. ElastiCache (Redis OSS) supports advanced data structures, such as, lists, sets, and hashes. It also offers features, such as pub/sub, geospatial indexes, and scripting.
- **Compliance requirements** – DAX doesn't currently offer the same compliance accreditations as as DynamoDB. For example, DAX hasn't obtained the SOC accreditation yet.

Configuring your DAX client

The DAX cluster is an instance-based cluster that can be accessed using various DAX SDKs. Each SDK provides developers with configurable options, such as requestTimeout and connections, to meet specific application requirements.

When configuring your DAX client, a crucial consideration is your client application's scale—specifically, the ratio of client instances to DAX server instances (which has a maximum of 11). Large client instance fleets can generate numerous connections to DAX server instances, potentially overwhelming them. This guide outlines best practices for DAX client configuration.

Best practices

1. **Client instances** – Implement singleton client instances to ensure instance reuse across requests. For implementation details, see the section called “Step 4: Run a sample application”.
2. **Request timeouts** – While applications often require low request timeouts to ensure minimal latency for upstream systems, setting timeouts too low can cause problems. Low timeouts may trigger frequent reconnection to server instances when DAX servers experience temporary latency spikes. When a timeout occurs, the DAX client terminates the existing server node connection and establishes a new one. Since connection establishment is resource-intensive, numerous consecutive connections can overload DAX servers. We recommend the following:

- Maintaining default request timeout settings.
- If lower timeouts are necessary, implement separate application threads with lower timeout values and include retry mechanisms with exponential back-off.

3. **Connection timeout** – For most applications, we recommend maintaining the default connection timeout settings.
4. **Concurrent connections** – Certain SDKs, such as JavaV2, allow adjustment of concurrent connections to the DAX server. Key considerations:
   - DAX server instances can handle up to 40,000 concurrent connections.
   - Default settings are suitable for most use cases.
   - Large client instances combined with high concurrent connections may overload servers.
   - Lower concurrent connection values reduce server overload risk.
   - Performance calculation example:
     - Assuming 1ms request latency, each connection can theoretically handle 1,000 requests/second.
     - For a 3-node cluster, a single client instance connecting to all nodes can process 3,000 requests/second.
     - With 10 connections, the client can handle approximately 30,000 requests/second.

     Recommendation – Begin with lower concurrent connection settings and validate through performance testing with expected production workload patterns.

Configuring your DAX cluster

The DAX cluster is a managed cluster, but you can adjust its configurations to fit your application requirements. Because of its close integration with DynamoDB API operations, you should consider the following aspects when integrating your application with DAX.

In this section

- DAX pricing
- Item cache and query cache
- Selecting TTL setting for the caches
- Caching multiple tables with a DAX cluster
- Data replication in DAX and DynamoDB global tables

- DAX Region availability
- DAX caching behavior

DAX pricing

The cost of a cluster depends on the number and size of nodes it has provisioned. Every node is billed for each hour it runs in the cluster. For more information, see Amazon DynamoDB pricing.

Cache hits don't incur DynamoDB cost, but impact DAX cluster resources. Cache misses incur DynamoDB read costs and require DAX resources. Writes incur DynamoDB write costs and impact DAX cluster resources to proxy the write.

Item cache and query cache

DAX maintains an item cache and a query cache. Understanding the differences between these caches can help you determine the performance and consistency characteristics they offer to your application.

Cache characteristic	Item cache	Query cache
Purpose	Stores the results of GetItem and BatchGetItem API operations.	Stores the results of Query and Scan API operations. These operations can return multiple items based on query conditions instead of specific item keys.
Access Type	Uses key-based access. When an application requests data using `GetItem` or `BatchGetItem` , DAX first checks the item cache using the primary key of the requested items. If the item is cached and unexpired , DAX returns it immediate	Uses parameter-based access. DAX caches the result set of `Query` and `Scan` API operations. DAX serves subsequent requests with the same parameters that include the same query conditions, table, index, from the cache. This significantly reduces response times and

Cache characteristic	Item cache	Query cache
	ly without accessing the DynamoDB table.	DynamoDB read throughput consumption.
Cache Invalidation	DAX automatically replicates updated items into the item cache of the nodes in the DAX cluster in the following scenarios: • You write an item update through the cache. • Read an updated item version from the table.	The query cache is more challenging to invalidate than the item cache. Item updates might not directly map to cached queries or scans. You must carefully tune the query cache TTL to maintain data consistency. Writes through DAX or base table aren't reflected in query cache until the TTL expires the previousl y cached response and DAX performs a new query against DynamoDB.
Global secondary index	Because the `GetItem` API operation isn't supported on local secondary indexes or global secondary indexes, the item cache only caches reads from the base table.	Query cache caches queries against both tables and indexes.

Selecting TTL setting for the caches

TTL determines the period for which data is stored in the cache before it becomes stale. After this period, the data is automatically refreshed on the next request. Choosing the right TTL setting for your DAX caches involves balancing between the optimization of application performance and consistency of data. Because there doesn't exist a universal TTL setting that works for all applications, the optimal TTL setting varies based on your application's specific characteristics and requirements. We recommend that you start with a conservative TTL setting using this prescriptive guidance. Then, iteratively adjust your TTL setting based on your application's performance data and insights.

DAX maintains a least recently used (LRU) list for the item cache. The LRU list tracks when items are first written to or last read from the cache. When the DAX node memory is full, DAX evicts older items even if they haven't expired yet to make room for new items. The LRU algorithm is always enabled and not user-configurable.

To set a TTL duration that works for your applications, consider the following points:

Understand your data access patterns

- **Read-heavy workloads** – For applications with read-heavy workloads and infrequent data updates, set a longer TTL duration to reduce the number of cache misses. A longer TTL duration also reduces the need to access the underlying DynamoDB table.
- **Write-heavy workloads** – For applications with frequent updates that aren't written through DAX, set a shorter TTL duration to ensure the cache stays consistent with the database. A shorter TTL duration also reduces the risk of serving stale data.

Evaluate your application's performance requirements

- **Latency sensitivity** – If your application requires low latency over data freshness, use a longer TTL duration. A longer TTL duration maximizes cache hits, which reduces average read latency.
- **Throughput and scalability** – A longer TTL duration reduces load on DynamoDB tables and improves throughput and scalability. However, you should balance this with the need for up-to-date data.

Analyze cache eviction and memory usage

- **Cache memory limits** – Monitor your DAX cluster's memory usage. A longer TTL duration can store more data in the cache, which might reach memory limits and lead to LRU-based evictions.

Use metrics and monitoring to adjust TTL

Regularly review metrics, for example, cache hits and misses, and CPU and memory utilization. Adjust your TTL setting based on these metrics to find an optimal balance between performance and data freshness. If cache misses are high and memory utilization is low, increase the TTL duration to increase the cache hit rate.

Consider business requirements and compliance

Data retention policies might dictate the maximum TTL duration you can set for sensitive or personal information.

Cache behavior if you set TTL to zero

If you set TTL to 0, the item cache and query cache present the following behaviors:

- **Item cache** – Items in the cache are refeshed only when an LRU eviction or a write-through operation occurs.
- **Query cache** – Query responses aren't cached.

Caching multiple tables with a DAX cluster

For workloads with multiple small DynamoDB tables that don't need individual caches, a single DAX cluster caches requests for these tables. This provides more flexible and efficient use of DAX, particularly for applications that access multiple tables and require high-performance reads.

Similar to the DynamoDB data plane APIs, DAX requests require a table name. If you use multiple tables in the same DAX cluster, you don't need any specific configuration. However, you must make sure that the cluster's security permissions allow access to all cached tables.

Considerations for using DAX with multiple tables

When you use DAX with multiple DynamoDB tables, you should consider the following points:

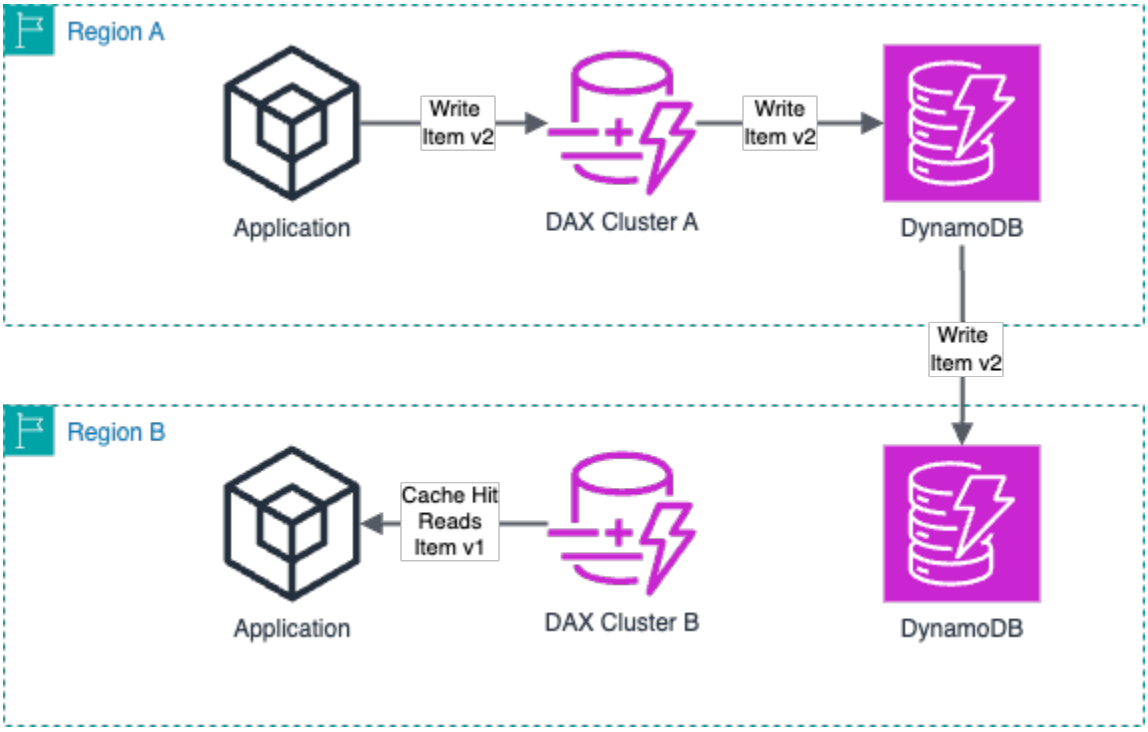
- **Memory management** – When you use DAX with multiple tables, you should consider the total size of your working data set. All the tables in your data set will share the same memory space of the node type you selected.
- **Resource allocation** – The DAX cluster's resources are shared among all the cached tables. However, a high-traffic table can cause eviction of data from the neighboring smaller tables.
- **Economies of scale** – Group smaller resources into a larger DAX cluster for averaging out traffic to a steadier pattern. For the total number of read resources that the DAX cluster requires, it's also economical to have three or more nodes. This also increases the availability of all the cached tables in the cluster.

Data replication in DAX and DynamoDB global tables

DAX is a Region-based service, so a cluster is only aware of the traffic within its AWS Region. Global tables write around the cache when they replicate data from another Region.

A longer TTL duration can cause stale data to remain in your secondary Region for longer than in the primary Region. This can result in cache misses in the local cache of the secondary Region.

The following diagram shows data replication occurring at the global table level in the source Region A. The DAX cluster in Region B isn't immediately aware of the newly replicated data from the source Region A.



DAX Region availability

Not all Regions that support DynamoDB tables support deploying DAX clusters. If your application requires low read latency through DAX, first review the list of Regions that support DAX. Then, select a Region for your DynamoDB table.

DAX caching behavior

DAX performs metadata and negative caching. Understanding these caching behaviors will help you effectively manage attribute metadata of cached items and negative cache entries.

- **Metadata caching** – DAX clusters indefinitely maintain metadata about the attribute names of cached items. This metadata persists even after the item expires or is evicted from the cache.

  Over time, applications that use unbounded number of attribute names can cause memory exhaustion in the DAX cluster. This limitation applies only to top-level attribute names, but not to the nested attribute names. Examples of unbounded attribute names include timestamps, UUIDs, and session IDs. Although you can use timestamps and session IDs as attribute values, we recommend to use shorter and more predictable attribute names.
- **Negative caching** – If a cache miss occurs and the read from a DynamoDB table yields no matching items, DAX adds a negative cache entry in the respective item or query cache. This entry remains until the cache TTL duration expires or a write-through occurs. DAX continues to return this negative cache entry for future requests.

  If the negative caching behavior doesn't fit your application pattern, read the DynamoDB table directly when DAX returns an empty result. We also recommend that you set a lower TTL cache duration to avoid long-lasting empty results in the cache and improve consistency with the table.

Sizing your DAX cluster

A DAX cluster's total capacity and availability depends on node type and count. More nodes in the cluster increase its read capacity, but not the write capacity. Larger node types (up to r5.8xlarge) can handle more writes, but too few nodes can impact availability when a node failure occurs. For more information about sizing your DAX cluster, see the DAX cluster sizing guide.

The following sections discuss the different sizing aspects that you should consider to balance node type and count for creating a scalable and cost-efficient cluster.

In this section

- Planning availability
- Planning write throughput
- Planning read throughput
- Planning dataset size
- Calculating approximate cluster capacity requirements
- Approximating cluster throughput capacity by node type
- Scaling write capacity in DAX clusters

Planning availability

When sizing a DAX cluster, you should first focus on its targeted availability. Availability of a clustered service, such as DAX, is a dimension of the total number of nodes in the cluster. Because a single node cluster has no tolerance for failure, its availability is equal to one node. In a 10-node cluster, the loss of a single node has a minimal impact to the cluster's overall capacity. This loss doesn't have a direct impact on availability because the remaining nodes can still fulfill read requests. To resume writes, DAX quickly nominates a new primary node.

DAX is VPC-based. It uses a subnet group to determine which Availability Zones it can run nodes in and which IP addresses to use from the subnets. For production workloads, we highly recommend that you use DAX with at least three nodes in different Availability Zones. This ensures that the cluster has more than one node left to handle requests even if a single node or Availability Zone fails. A cluster can have up to 11 nodes, where one is a primary node and 10 are read replicas.

Planning write throughput

All DAX clusters have a primary node for write-through requests. The size of the node type for the cluster determines its write capacity. Adding additional read replicas doesn't increase the cluster's write capacity. Therefore, you should consider the write capacity during cluster creation because you can't change the node type later.

If your application needs to write-through DAX to update the item cache, consider increased use of cluster resources to facilitate the write. Writes against DAX consume about 25 times more resources than cache-hit reads. This might require a larger node type than for read-only clusters.

For additional guidance about determining whether write-through or write-around will work best for your application, see Strategies for writes.

Planning read throughput

A DAX cluster's read capacity depends on the cache hit ratio of your workload. Because DAX reads data from DynamoDB when a cache miss occurs, it consumes approximately 10 times more cluster resources than a cache-hit. To increase cache hits, increase the TTL setting of the cache to define the period for which an item is stored in the cache. A higher TTL duration, however, increases the chance of reading older item versions unless updates are written through DAX.

To make sure that the cluster has sufficient read capacity, scale the cluster horizontally as mentioned in Scaling a cluster horizontally. Adding more nodes adds read replicas to the pool of resources, while removing nodes reduces read capacity. When you select the number of nodes

and their sizes for a cluster, consider both the minimum and maximum amount of read capacity needed. If you can't horizontally scale a cluster with smaller node types to meet your read requirements, use a larger node type.

Planning dataset size

Each available node type has a set memory size for DAX to cache data. If a node type is too small, the working set of data that an application requests won't fit in memory and results in cache misses. Because larger nodes support larger caches, use a node type larger than the estimated data set that you need to cache. A larger cache also improves the cache hit ratio.

You might get diminishing returns for caching items with few repeated reads. Calculate the memory size for frequently accessed items and make sure the cache is large enough to store that data set.

Calculating approximate cluster capacity requirements

You can estimate your workload's total capacity needs to help you select the appropriate size and quantity of cluster nodes. To do this estimation, calculate the variable *normalized request per second* (Normalized RPS). This variable represents the total units of work your application requires the DAX cluster to support, including cache hits, cache misses, and writes. To calculate the Normalized RPS, use the following inputs:

- `ReadRPS_CacheHit` – Specifies the number of reads per second that result in a cache hit.
- `ReadRPS_CacheMiss` – Specifies the number of reads per second that result in a cache miss.
- `WriteRPS` – Specifies the number of writes per second that will go through DAX.
- `DaxNodeCount` – Specifies the number of nodes in the DAX cluster.
- `Size` – Specifies the size of the item being written or read in KB rounded up to the nearest KB.
- `10x_ReadMissFactor` – Represents a value of 10. When a cache miss occurs, DAX uses approximately 10 times more resources than cache hits.
- `25x_WriteFactor` – Represents a value of 25 because a DAX write-through uses approximately 25 times more resources than cache hits.

Using the following formula, you can calculate the Normalized RPS.

```
Normalized RPS = (ReadRPS_CacheHit * Size) + (ReadRPS_CacheMiss * Size *
 10x_ReadMissFactor) + (WriteRequestRate * 25x_WriteFactor * Size * DaxNodeCount)
```

For example, consider the following input values:

- `ReadRPS_CacheHit` = 50,000
- `ReadRPS_CacheMiss` = 1,000
- `ReadMissFactor` = 1
- `Size` = 2 KB
- `WriteRPS` = 100
- `WriteFactor` = 1
- `DaxNodeCount` = 3

By substituting these values in the formula, you can calculate the Normalized RPS as follows.

```
Normalized RPS = (50,000 Cache Hits/Sec * 2KB) + (1,000 Cache Misses/Sec * 2KB * 10) +
 (100 Writes/Sec * 25 * 2KB * 3)
```

In this example, the calculated value of Normalized RPS is 135,000. However, this Normalized RPS value doesn't account for keeping cluster utilization below 100% or node loss. We recommend that you factor in additional capacity. To do this, determine the greater of two multiplying factors: target utilization or node loss tolerance. Then, multiply the Normalized RPS by the greater factor to obtain a *target request per second* (Target RPS).

- **Target utilization**

  Because performance impacts increase cache misses, we don't recommend running the DAX cluster at 100% utilization. Ideally, you should keep cluster utilization at or below 70%. To achieve this, multiply the Normalized RPS by 1.43.

- **Node loss tolerance**

  If a node fails, your application must be able to distribute its requests among the remaining nodes. To make sure nodes stay below 100% utilization, choose a node type large enough to absorb extra traffic until the failed node comes back online. For a cluster with fewer nodes, each node must tolerate larger traffic increases when one node fails.

  If a primary node fails, DAX automatically fails over to a read replica and designates it as the new primary. If a replica node fails, other nodes in the DAX cluster can still serve requests until the failed node is recovered.

For example, a 3-node DAX cluster with a node failure requires an additional 50% capacity on the remaining two nodes. This requires a multiplying factor of 1.5. Conversely, an 11-node cluster with a failed node requires an additional 10% capacity on the remaining nodes or a multiplying factor of 1.1.

Using the following formula, you can calculate the Target RPS.

```
Target RPS = Normalized RPS * CEILING(TargetUtilization, NodeLossTolerance)
```

For example, to calculate Target RPS, consider the following values:

- `Normalized RPS` = 135,000
- `TargetUtilization` = 1.43

  Because we're aiming for a maximum cluster utilization of 70%, we're setting `TargetUtilization` to 1.43.
- `NodeLossTolerance` = 1.5

  Say that we're using a 3-node cluster, therefore, we're setting `NodeLossTolerance` to 50% capacity.

By substituting these values in the formula, you can calculate the Target RPS as follows.

```
Target RPS = 135,000 * CEILING(1.43, 1.5)
```

In this example, because the value of `NodeLossTolerance` is greater than `TargetUtilization`, we calculate the value of Target RPS with `NodeLossTolerance`. This gives us a Target RPS of 202,500, which is the total amount of capacity the DAX cluster must support. To determine the number of nodes you'll need in a cluster, map the Target RPS to an appropriate column in the following table. For this example of a Target RPS of 202,500, you need the dax.r5.large node type with three nodes.

Approximating cluster throughput capacity by node type

Using the Target RPS formula, you can estimate cluster capacity for different node types. The following table shows approximate capacities for clusters with 1, 3, 5, and 11 node types. These

capacities don't replace the need to perform load testing of DAX with your own data and request patterns. Additionally, these capacities don't include t-type instances because of their lack of fixed CPU capacity. The unit for all values in the following table is Normalized RPS.

Node type (memory)	1 node	3 nodes	5 nodes	11 nodes
dax.r5.24xlarge (768GB)	1M	3M	5M	11M
dax.r5.16xlarge (512GB)	1M	3M	5M	11M
dax.r5.12xlarge (384GB)	1M	3M	5M	11M
dax.r5.8xlarge (256GB)	1M	3M	5M	11M
dax.r5.4xlarge (128GB)	600k	1.8M	3M	6.6M
dax.r5.2xlarge (64GB)	300k	900k	1.5M	3.3M
dax.r5.xlarge (32GB)	150k	450k	750k	1.65M
dax.r5.large (16GB)	75k	225k	375k	825k

Because of the maximum limit of 1 million NPS (network operations per second) for each node, nodes of types dax.r5.8xlarge or larger don't contribute additional cluster capacity. Node types larger than 8xlarge might not contribute to total throughput capacity of the cluster. However, such node types can be helpful for storing a larger working data set in memory.

Scaling write capacity in DAX clusters

Each write to DAX consumes 25 normalized requests on every node. Because there's a 1 million RPS limit for each node, a DAX cluster is limited to 40,000 writes per second, not accounting for read usage.

If your use case requires more than 40,000 writes per second in the cache, you must use separate DAX clusters and shard the writes among them. Similar to DynamoDB, you can hash the partition key for the data you're writing to the cache. Then, use modulus to determine which shard to write the data to.

The following example calculates the hash of an input string. It then calculates the modulus of the hash value with 10.

```
def hash_modulo(input_string):
    # Compute the hash of the input string
    hash_value = hash(input_string)

    # Compute the modulus of the hash value with 10
    bucket_number = hash_value % 10

    return bucket_number

#Example usage
if _name_ == "_main_":
    input_string = input("Enter a string: ")
    result = hash_modulo(input_string)
    print(f"The hash modulo 10 of '{input_string}' is: {result}.")
```

Deploying a cluster

Creating a new DAX cluster requires configurations beyond those needed for DynamoDB. These configurations are particularly for networking because DAX is based on Amazon VPC. This gives you complete control over your virtual networking environment, including resource placement, connectivity, and security. This section presents the best practices for the settings needed during cluster creation.

For information about choosing cluster nodes, see Sizing your DAX cluster.

In this section

- Configure networks

- Configure security
- Parameter group
- Maintenance window

Configure networks

DAX uses a subnet group to determine which Availability Zones it can run nodes in and which IP addresses to use from the subnets. To minimize latency between your application and DAX, the subnets and Availability Zones for your application servers and the DAX cluster should be the same.

We recommend that you spread the DAX nodes across multiple Availability Zones. The default option of Automatic allocation does this for you.

For best practices about setting up your VPC, see Get started with Amazon VPC in the *Amazon VPC User Guide*.

Configure security

This section discusses the security measures that you should implement for your applications that use DAX. This section also briefly discusses the support that DAX includes for data encryption.

IAM

DAX and DynamoDB have separate access control mechanisms. DAX requires an IAM role to access your DynamoDB tables. This role should follow the principle of least privilege and grant access only to specific tables and DynamoDB operations, such as GetItem and PutItem. For more information about the access control mechanisms provided by DAX, see DAX access control.

Encryption

You configure encryption at rest and encryption in transit while creating a DAX cluster. These are enabled by default. We recommend that you keep the default encryption settings unless business requirements prevent it. For more information, see DAX encryption at rest and DAX encryption in transit.

Parameter group

DAX applies a set of configurations on every node in a cluster called a parameter group. You can change this configuration after creating the cluster.

The DAX parameter group holds TTL settings for item cache and query cache. By default, the TTL duration is 5 minutes. You can override the TTL duration to any integer value greater than or equal to 1 millisecond.

You can't modify parameter groups when a running DAX instance is using them. You can change the parameter group values during the downtime of a DAX cluster.

Maintenance window

To allow for occasional software upgrades and patches to your nodes, a weekly maintenance window is configured for the DAX cluster. During this window, DAX performs rolling updates to the nodes. Clusters with more than one node don't lose availability of the cluster during these updates, but have reduced cluster capacity until the node returns. If your organization has a predictable time of low usage, consider setting the maintenance window manually to this time.

Managing cluster operations

DAX handles the cluster's maintenance and health for you. However, you need to provide operational input to scale the cluster horizontally or vertically to match your usage patterns. This section describes the recommended process to scale your DAX clusters.

In this section

- Scaling a cluster horizontally
- Scaling a cluster vertically

Scaling a cluster horizontally

Scaling a DAX cluster involves adjusting its capacity to meet throughput demands. This adjustment is done by increasing or decreasing the number of nodes (replicas) in the cluster while it's running. This process, known as horizontal scaling, helps distribute the workload across more nodes or consolidate to fewer nodes when demand is low.

You can horizontally scale your DAX cluster in and out using the `decrease-replication-factor` or `increase-replication-factor` commands in the AWS CLI.

Increase replication factor (scale out)

Increasing the replication factor of a DAX cluster adds more nodes to the cluster. The following example shows the usage of the `increase-replication-factor` command.

```
aws dax increase-replication-factor \
    --cluster-name yourClusterName  \
    --new-replication-factor desiredReplicationFactor
```

- In this command, the `cluster-name` argument specifies the name of your cluster. For example, *yourClusterName*.
- The `new-replication-factor` argument specifies the total number of nodes to add in the cluster after scaling. This includes the primary node and replica nodes. For example, if your cluster currently has 3 nodes and you want to add 2 more nodes, set the value of `new-replication-factor` to 5.

Decrease replication factor (scale in)

Decreasing the replication factor of a DAX cluster removes nodes from the cluster. Removing nodes can help reduce cost during periods of low demand. The following example shows the usage of the `decrease-replication-factor` command.

```
aws dax decrease-replication-factor \
    --cluster-name yourClusterName  \
    --new-replication-factor desiredReplicationFactor
```

- In this command, the `cluster-name` argument specifies the name of your cluster. For example, *yourClusterName*.
- The `new-replication-factor` argument specifies the reduced number of nodes in your cluster after scaling. This number must be lower than the current replication factor and must include the primary node. For instance, if your cluster has 5 nodes and you want to remove 2 nodes, set the value of `new-replication-factor` to 3.

Horizontal scaling considerations

Consider the following when you plan horizontal scaling:

- **Primary node** – The DAX cluster includes a primary node. The replication factor includes this primary node. For example, a replication factor of 3 means one primary node and two replica nodes.
- **Availability** – Adding or removing DAX nodes changes the cluster's availability and fault tolerance. More nodes can improve availability, but they also increase costs.

- **Data migration** – When you increase the replication factor, DAX automatically handles data distribution across the new set of nodes. When a new node begins serving traffic, its cache is already warmed. However, during this process, there might be a temporary impact on performance during data migration.

Monitor your DAX clusters closely during and after the scaling process to verify that they're performing as expected, and make further adjustments as necessary.

Scaling a cluster vertically

To vertically scale the node size of an existing cluster, you need to create a new cluster and migrate the application traffic to the new cluster. Migrating to a new cluster with different nodes involves several steps to ensure a smooth transition with minimal impact on your application's performance and availability.

To create a new cluster for scaling your node size vertically, consider the following points:

- **Access your current setup** – Review the metrics of your current DAX cluster to determine the new node size and quantity you need. Use this information as input to define your cluster size. For information, see Sizing your DAX cluster.
- **Set up a new DAX cluster** – Create a new DAX cluster with the node type and quantity you determined. You can use the existing configuration settings from your parameter group, unless you need to make adjustments.
- **Synchronize data** – Because DAX is a caching layer for DynamoDB, you don't need to migrate data directly. However, the new DAX cluster won't have any of your working dataset in memory until you send traffic to it.
- **Update application configuration** – Update your application's configuration to point to the new DAX cluster's endpoint. You might need to change code or update environment variables, depending on your application's configuration.

  To reduce impact when you switch to a new cluster, send canary traffic to the new cluster from a small portion of your application fleet. You can do this by slowly rolling out application updates or by using a weight-based routing DNS entry in front of your DAX endpoint.
- **Monitor and optimize** – After you switch to the new DAX cluster, closely monitor its performance metrics and logs for any issues. Be ready to adjust the number of nodes based on updated workload patterns.

Until the new cluster caches your working dataset properly, you'll see higher cache miss rates and latencies.

- **Decommission old cluster** – When you're sure that the new cluster is performing as expected, safely decommission the old DAX cluster to avoid unnecessary costs.

Monitoring DAX

You can monitor key metrics, for example cache hit ratio, to ensure optimal DAX cluster performance, diagnose issues, and determine when you need to scale the cluster. Regularly checking key metrics helps you maintain performance, stability, and cost-efficiency by scaling the cluster to match your workload requirements. For more information about monitoring DAX, see Production monitoring.

The following list presents some of the key metrics you should monitor:

- **Cache hit ratio** – Shows how effectively DAX serves cached data, reducing the need to access the underlying DynamoDB tables. Few cache misses for the cluster indicate good caching efficiency. But few cache hits suggest that you might need to revisit the caching TTL setting or the workload isn't a good fit for caching.

  Use Amazon CloudWatch to calculate your DAX cluster's cache hit ratio. Compare the `ItemCacheHits`, `ItemCacheMisses`, `QueryCacheHits`, and `QueryCacheMisses` metrics to get this ratio. The following formula shows how the cache hit ratio is calculated. To calculate the ratio using this formula, divide your cache hits by the sum of your cache hits and misses.

  ```
  Cache hit ratio = Cache hits / (Cache hits + Cache misses)
  ```

  The cache hit ratio is a number between 0 and 1, which is represented as a percentage. A higher percentage indicates better overall cache utilization.
- **ErrorRequestCount** – Count of requests that resulted in user errors reported by the node or cluster. `ErrorRequestCount` includes requests that were throttled by the node or cluster. Monitoring user errors can help you identify scaling misconfigurations or hot item/partition patterns in your application.
- **Operation latencies** – Monitoring the latency of read and write operations to and from the DAX cluster can help you in identifying performance bottlenecks. Increasing latencies might indicate issues with your DAX cluster configuration, network, or the need to scale.

- **Network consumption** – Keep an eye on the `NetworkBytesIn` and `NetworkBytesOut` metrics to monitor your DAX cluster's network traffic. An unexpected increase in network throughput could mean more client requests or inefficient query patterns that are causing more data to be transferred.

  Monitoring network consumption helps you manage costs for your DAX cluster. It also ensures the network doesn't become a bottleneck for cluster performance.

- **Eviction rate** – Shows how often items are removed from your cache to make room for new items. If the eviction rate increases over time, your cache might be too small or your caching strategy isn't effective.

  Monitor the `EvictedSize` metric in CloudWatch to determine if your cache size is adequate for your workload. If the total evicted size keeps growing, you might need to scale up your DAX cluster to accommodate a larger cache.

- **CPU utilization** – Refers to the percentage of CPU utilization of the node or cluster. This is a critical metric to monitor for any database or caching system. High CPU utilization could mean your DAX cluster might be overloaded and needs scaling to handle the increased demand.

  Monitor the `CPUUtilization` metric for your DAX cluster. If your CPU utilization consistently approaches or exceeds 70-80%, consider scaling up your DAX cluster as described in the following section.

  If the number of requests sent to DAX exceeds a node's capacity, DAX limits the rate at which it accepts additional requests. It does this by returning a ThrottlingException. DAX continuously evaluates your cluster's CPU utilization to determine the request volume it can process while maintaining a healthy cluster state.

  You can monitor the `ThrottledRequestCount` metric that DAX publishes to CloudWatch. If you see these exceptions regularly, you should consider scaling up your cluster.

Scaling your DAX cluster using monitoring data

You can determine if you need to scale up or down your DAX cluster by monitoring its performance metrics.

- **Scale up or out** – If your DAX cluster has high CPU utilization, low cache hits (after optimizing the caching strategy), or high operation latencies, you should scale up your cluster. Adding more

nodes, also called scaling out, can help distribute the load more evenly. For workloads with increasing writes per second, you might need to choose more powerful nodes (scaling up).

- **Scale down** – If you consistently see low CPU utilization and operation latencies below your thresholds, you might have over-provisioned resources. In such cases, scale down nodes to reduce costs. You can reduce the number of nodes down to 1 during low utilization periods, but you can't shut the cluster down entirely.

Best practices for PITR recovery in DynamoDB

The following are the best practices for using point-in-time recovery (PITR) to return a table to a previous state.

Use these best practices if you notice mistaken writes to your table that you want to reverse. You can either restore the full table from a point in time, or roll back specific unwanted writes in-place.

Topics

- Recovery by initiating a table restore
- Recovery by rolling back unwanted writes in-place

Recovery by initiating a table restore

With PITR, you can restore a table to any specific second in the PITR recovery window. The PITR recovery window begins when PITR is enabled and holds up to 35 days of history. You can also configure it for a shorter duration.

Consider the following when you initiate a full PITR table restore:

- The restore creates a new table. A table restore action does not operate in-place on top of the original table. For in-place options, see Recovery by rolling back unwanted writes in-place.
- You can restore to a new table in the same Region or to a different Region. Restoring to a different Region incurs data transfer charges.
- You can restore the table with or without secondary indexes. Restoring without secondary indexes can be faster and more cost efficient.
- The restore can take several hours to complete. Restore time varies based on multiple factors and doesn't always correlate with table size.

After the PITR table restore, you can put the new table into service as a full replacement for the original. You can also compare it to the original table to find differences. For a simpler approach, see Recovery by rolling back unwanted writes in-place.

Consider the following when you put a restored table into service:

- For infrastructure as code environments (AWS CloudFormation, AWS Cloud Development Kit (AWS CDK), Terraform), adopt the restored table into your IaC environment to bring it under management.
- Update client connections to refer to the new table by its new name.
- Re-add stream settings if they were on the original. The DynamoDB stream name includes the time of stream creation, so the new stream has a different name than the old stream. Update any references to the old stream name in IAM or in downstream consumer code.
- Re-enable PITR on the new table if it was on the original.
- Re-enable deletion protection on the new table if it was on the original.
- Re-add tags to the new table if tags were on the original.
- Re-add the resource-based policies on the new table if RBPs were on the original.
- Update any cross-account access IAM policies that reference the original table.
- Adjust the auto scaling settings on the new table.
- Set the TTL attribute on the new table if TTL was on the original.
- Adjust the table class on the new table if the original had a custom table class.
- Review the warm throughput settings on the new table and raise the read and write values if necessary.
- Add replicas for the new table to match the original table if it was a global table.
- Delete the original table after the restored table has been fully configured and put into service.

If restoring an MRSC global table, the newly restored table cannot be made into an MRSC table because only empty tables can be made into MRSC tables. One solution is to restore the table and then copy the data from the restored table into an empty MRSC table.

Recovery by rolling back unwanted writes in-place

To keep the original table in service, you can roll back unwanted writes directly rather than restoring a full table. You can roll back all the writes or only those writes that you identify as mistakes.

Before you begin, make sure that PITR is enabled on the table and that the time period of the unwanted writes falls within the PITR recovery window.

This approach uses the incremental export to Amazon Simple Storage Service (Amazon S3) feature. An incremental export writes the changed items to Amazon S3. The export includes each item's old and new images. The time period can be as short as 15 minutes or as long as 24 hours. The time period must be contained within the PITR recovery window.

To roll back unwanted writes

1. Perform an incremental export to Amazon S3. Specify the time period during which the erroneous writes were happening to the table. Select an export view of "new and old images". If the time period exceeds 24 hours, do multiple incremental export jobs that together cover the full time period exactly.
2. Drive a bulk job off the Amazon S3 data to reverse the changes listed in the export by writing the old item value back. Optionally apply a transformation to control exactly what gets undone and how (such as to correct minor mistakes on the items).

To drive this bulk job, you can use the open-source Bulk Executor for DynamoDB. For more information about the tool, see Introducing open source Bulk Executor for Amazon DynamoDB on the AWS Database Blog. For a step-by-step example of rolling back unwanted writes with this approach, see Recover from accidental DynamoDB changes using Bulk Executor on the AWS Database Blog. Bulk Executor is open source and does not include any official support.

This approach provides the following advantages:

- More cost effective, especially for large tables. Instead of restoring a full table to undo a small number of mistaken writes, you focus on just the mistakes.
- Faster, especially for large tables. Only a subset of table data must be processed.
- Live, in-place correction. The original table remains active during the correction. No need to adjust a new table's metadata, settings, and external references.

Using DynamoDB with other AWS services

Amazon DynamoDB is integrated with other AWS services, letting you automate repeating tasks or build applications that span multiple services.

- Best practices for integrating with DynamoDB

Configuring AWS credentials using Amazon Cognito for DynamoDB

The recommended way to obtain AWS credentials for your web and mobile applications is to use Amazon Cognito. Amazon Cognito helps you avoid hardcoding your AWS credentials on your files. It uses AWS Identity and Access Management (IAM) roles to generate temporary credentials for your application's authenticated and unauthenticated users.

For example, to configure your JavaScript files to use an Amazon Cognito unauthenticated role to access the Amazon DynamoDB web service, do the following.

To configure credentials to integrate with Amazon Cognito

1. Create an Amazon Cognito identity pool that allows unauthenticated identities.

```
aws cognito-identity create-identity-pool \
    --identity-pool-name DynamoPool \
    --allow-unauthenticated-identities \
    --output json
```

```
{
    "IdentityPoolId": "us-west-2:12345678-1ab2-123a-1234-a12345ab12",
    "AllowUnauthenticatedIdentities": true,
    "IdentityPoolName": "DynamoPool"
}
```

2. Copy the following policy into a file named `myCognitoPolicy.json`. Replace the identity pool ID (*us-west-2:12345678-1ab2-123a-1234-a12345ab12*) with your own `IdentityPoolId` obtained in the previous step.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "cognito-identity.amazonaws.com"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "cognito-identity.amazonaws.com:aud": "us-
west-2:12345678-1ab2-123a-1234-a12345ab12"
        },
        "ForAnyValue:StringLike": {
          "cognito-identity.amazonaws.com:amr": "unauthenticated"
        }
      }
    }
  ]
}
```

3. Create an IAM role that assumes the previous policy. In this way, Amazon Cognito becomes a trusted entity that can assume the `Cognito_DynamoPoolUnauth` role.

```
aws iam create-role --role-name Cognito_DynamoPoolUnauth \
--assume-role-policy-document file://PathToFile/myCognitoPolicy.json --output json
```

4. Grant the `Cognito_DynamoPoolUnauth` role read-only access to DynamoDB by attaching a managed policy (`AmazonDynamoDBReadOnlyAccess`). Because this role is assumed by

unauthenticated users, follow the principle of least privilege and grant only the permissions the role actually needs.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
AmazonDynamoDBReadOnlyAccess \
--role-name Cognito_DynamoPoolUnauth
```

> **Note**
>
> Alternatively, you can grant fine-grained access to DynamoDB. For more information, see Using IAM policy conditions for fine-grained access control.

5. Obtain and copy the IAM role Amazon Resource Name (ARN).

```
aws iam get-role --role-name Cognito_DynamoPoolUnauth --output json
```

6. Add the `Cognito_DynamoPoolUnauth` role to the `DynamoPool` identity pool. The format to specify is `KeyName=string`, where `KeyName` is `unauthenticated` and the string is the role ARN obtained in the previous step.

```
aws cognito-identity set-identity-pool-roles \
--identity-pool-id "us-west-2:12345678-1ab2-123a-1234-a12345ab12" \
--roles unauthenticated=arn:aws:iam::123456789012:role/Cognito_DynamoPoolUnauth --
output json
```

7. Specify the Amazon Cognito credentials in your files. Modify the `IdentityPoolId` and `RoleArn` accordingly.

```
AWS.config.credentials = new AWS.CognitoIdentityCredentials({
IdentityPoolId: "us-west-2:12345678-1ab2-123a-1234-a12345ab12",
RoleArn: "arn:aws:iam::123456789012:role/Cognito_DynamoPoolUnauth"
});
```

You can now run your JavaScript programs against the DynamoDB web service using Amazon Cognito credentials. For more information, see Setting credentials in a web browser in the *AWS SDK for JavaScript Getting Started Guide*.

Integrating with Amazon Redshift

Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools.

DynamoDB and Amazon Redshift can be used together to address different data storage and processing needs within an application or data ecosystem.

See the topics below for more detailed topics on how to integrate DynamoDB with Amazon Redshift.

Topics

- Cross-account integration considerations with CMK
- DynamoDB zero-ETL integration with Amazon Redshift
- Loading data from DynamoDB into Amazon Redshift with the COPY command

Cross-account integration considerations with CMK

When you attempt to integrate from DynamoDB to Amazon Redshift, the initial action is launched from Amazon Redshift. Without the proper permissions, this action could result in a silent failure. The following sections detail the permissions required for this cross-account integration.

Required AWS KMS policies and permissions

Replace the following placeholders in the examples:

- `111122223333`: The AWS account ID where Amazon Redshift is hosted
- `444455556666`: The AWS account ID where DynamoDB is hosted
- `REDSHIFT_ROLE_NAME`: The IAM role name used by Amazon Redshift
- `REGION`: The AWS Region where your resources are located
- `TABLE_NAME`: The name of your DynamoDB table
- `KMS_KEY_ID`: The ID of your KMS key

KMS key policy in the DynamoDB account

The following AWS KMS key policy enables cross-account access between your DynamoDB and Amazon Redshift services. In this example, account 444455556666 contains the DynamoDB table and AWS KMS key, while account 111122223333 contains the Amazon Redshift cluster that needs access to decrypt the data.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Enable IAM User Permissions",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::444455556666:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "Allow Redshift to use the key",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/REDSHIFT_ROLE_NAME"
            },
            "Action": [
                "kms:Decrypt",
                "kms:DescribeKey",
                "kms:GenerateDataKey",
                "kms:GenerateDataKeyWithoutPlaintext"
            ],
            "Resource": "*"
        }
    ]
}
```

IAM Policy for the Amazon Redshift role (in Amazon Redshift account)

The following IAM policy allows a Amazon Redshift service to access DynamoDB tables and their associated AWS KMS encryption keys in a cross-account scenario. In this example, account 444455556666 contains the DynamoDB resources and AWS KMS keys that the Amazon Redshift service needs to access.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDynamoDBAccess",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeTable",
                "dynamodb:BatchGetItem",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:BatchGetItem",
                "dynamodb:GetItem",
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator",
                "dynamodb:DescribeStream",
                "dynamodb:ListStreams"
            ],
            "Resource": [
                "arn:aws:dynamodb:*:444455556666:table/TABLE_NAME",
                "arn:aws:dynamodb:*:444455556666:table/TABLE_NAME/stream/*"
            ]
        },
        {
            "Sid": "AllowKMSAccess",
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "kms:DescribeKey",
                "kms:GenerateDataKey",
                "kms:GenerateDataKeyWithoutPlaintext"
            ],
            "Resource": "arn:aws:kms:us-east-1:444455556666:key/KMS_KEY_ID"
```

```
        }
    ]
}
```

Trust relationship for the Amazon Redshift role

JSON

```

    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

DynamoDB Table policy (if using resource-based policies)

The following resource-based policy allows a Amazon Redshift service in account 111122223333 to access DynamoDB tables and Streams in account 444455556666. Attach this policy to your DynamoDB table to enable cross-account access.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRedshiftAccess",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/REDSHIFT_ROLE_NAME"
            },
            "Action": [
```

```
                "dynamodb:DescribeTable",
                "dynamodb:BatchGetItem",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:BatchGetItem",
                "dynamodb:GetItem",
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator",
                "dynamodb:DescribeStream",
                "dynamodb:ListStreams"
            ],
            "Resource": [
                "arn:aws:dynamodb:*:444455556666:table/TABLE_NAME",
                "arn:aws:dynamodb:*:444455556666:table/TABLE_NAME/stream/*"
            ]
        }
    ]
}
```

Important considerations

1. Ensure the KMS key is in the same region as your DynamoDB table.
2. The KMS key must be a customer managed key (CMK), not an AWS managed key.
3. If you're using DynamoDB global tables, configure permissions for all relevant regions.
4. Consider adding condition statements to restrict access based on VPC endpoints or IP ranges.
5. For enhanced security, consider using `aws:PrincipalOrgID` condition to restrict access to your organization.
6. Monitor KMS key usage through CloudTrail and CloudWatch metrics.

DynamoDB zero-ETL integration with Amazon Redshift

Amazon DynamoDB zero-ETL integration with Amazon Redshift enables seamless analytics on DynamoDB data without any coding. This fully-managed feature automatically replicates DynamoDB tables into an Amazon Redshift database so users can run SQL queries and analytics on their DynamoDB data without having to set up complex ETL processes. The integration works by replicating data from the DynamoDB table to the Amazon Redshift database.

To set up the integration, simply specify a DynamoDB table as the source and an Amazon Redshift database as the target. On activation, the integration exports the full DynamoDB table to populate the Amazon Redshift database. The time it takes for this initial process to complete depends on the DynamoDB table size. The zero-ETL integration then incrementally replicates updates from DynamoDB to Amazon Redshift every 15-30 minutes using DynamoDB incremental exports. This means the replicated DynamoDB data in Amazon Redshift is kept up-to-date automatically.

After it is configured, you can analyze the DynamoDB data in Amazon Redshift using standard SQL clients and tools, without impacting DynamoDB table performance. By eliminating cumbersome ETL, this zero-ETL integration provides a fast, easy way to unlock insights from DynamoDB through Amazon Redshift analytics and machine learning capabilities.

Topics

- Prerequisites before creating a DynamoDB zero-ETL integration with Amazon Redshift
- Limitations when using DynamoDB zero-ETL integrations with Amazon Redshift
- Creating a DynamoDB zero-ETL integration with Amazon Redshift
- Viewing DynamoDB zero-ETL integrations with Amazon Redshift
- Deleting DynamoDB zero-ETL integrations with Amazon Redshift

Prerequisites before creating a DynamoDB zero-ETL integration with Amazon Redshift

1. You must have your source DynamoDB table and target Amazon Redshift cluster created before creating an integration. This information is covered in Step 1: Configuring a source DynamoDB table and Step 2: Creating an Amazon Redshift data warehouse.
2. A zero-ETL integration between Amazon DynamoDB and Amazon Redshift requires your source DynamoDB table to have Point-in-time recovery (PITR) enabled.
3. For **resource-based policies**, the zero-ETL integration requires a resource-based policy attached directly to your DynamoDB table. This inline policy grants the Amazon Redshift service permission to access your table data for replication. For more information about resource-based policies for DynamoDB, see Using resource-based policies for DynamoDB.

   If you create the integration where your DynamoDB table and Amazon Redshift data warehouse are in the same account, you can use the **Fix it for me** option during the create integration step to automatically apply the required resource policies to both DynamoDB and Amazon Redshift.

If you create an integration where your DynamoDB table and Amazon Redshift data warehouse are in different AWS accounts, you will need to manually apply the following resource policy on your DynamoDB table.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid":
 "StatementthatallowsAmazonRedshiftservicetoDescribeTableandExportTable",
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": [
                "dynamodb:ExportTableToPointInTime",
                "dynamodb:DescribeTable"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                },
                "ArnEquals": {
                    "aws:SourceArn": "arn:aws:redshift:us-
east-1:111122223333:integration:*"
                }
            }
        },
        {
            "Sid":
 "StatementthatallowsAmazonRedshiftservicetoDescribeTableandExportTable",
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": "dynamodb:DescribeExport",
            "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/table-
name/export/*",
            "Condition": {
                "StringEquals": {
```

```
                    "aws:SourceAccount": "111122223333"
                },
                "ArnEquals": {
                    "aws:SourceArn": "arn:aws:redshift:us-
east-1:111122223333:integration:*"
                }
            }
        }
    ]
}
```

You might also need to configure the resource policy on your Amazon Redshift data warehouse. For more information, see Configure authorization using the Amazon Redshift API.

4. **For Identity-based policies:**

a. The user creating the integration requires an identity-based policy that authorizes the following actions: `GetResourcePolicy`, `PutResourcePolicy`, and `UpdateContinuousBackups`.

> **Note**
>
> The following policy examples will show the resource as `arn:aws:redshift{-serverless}`. This is an example to show that the arn can be either `arn:aws:redshift` or `arn:aws:redshift-serverless` depending on if your namespace is an Amazon Redshift cluster or Amazon Redshift Serverless namespace.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:ListTables"
            ],
            "Resource": "*"
        },
```

```
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetResourcePolicy",
                "dynamodb:PutResourcePolicy",
                "dynamodb:UpdateContinuousBackups"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-east-1:111122223333:table/table-name"
            ]
        },
        {
            "Sid": "AllowRedshiftDescribeIntegration",
            "Effect": "Allow",
            "Action": [
                "redshift:DescribeIntegrations"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowRedshiftCreateIntegration",
            "Effect": "Allow",
            "Action": "redshift:CreateIntegration",
            "Resource": "arn:aws:redshift:us-
east-1:111122223333:integration:*"
        },
        {
            "Sid": "AllowRedshiftModifyDeleteIntegration",
            "Effect": "Allow",
            "Action": [
                "redshift:ModifyIntegration",
                "redshift:DeleteIntegration"
            ],
            "Resource": "arn:aws:redshift:us-
east-1:111122223333:integration:uuid"
        },
        {
            "Sid": "AllowRedshiftCreateInboundIntegration",
            "Effect": "Allow",
            "Action": "redshift:CreateInboundIntegration",
            "Resource": "arn:aws:redshift:us-
east-1:111122223333:namespace:uuid"
        }
    ]
```

```
}
```

b. The user responsible for configuring the destination Amazon Redshift namespace requires an identity-based policy that authorizes the following actions: `PutResourcePolicy`, `DeleteResourcePolicy`, and `GetResourcePolicy`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "redshift:PutResourcePolicy",
                "redshift:DeleteResourcePolicy",
                "redshift:GetResourcePolicy"
            ],
            "Resource": [
                "arn:aws:redshift:us-east-1:111122223333:cluster:cluster-
name"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "redshift:DescribeInboundIntegrations"
            ],
            "Resource": [
                "arn:aws:redshift:us-east-1:111122223333:cluster:cluster-
name"
            ]
        }
    ]
}
```

5. **Encryption key permissions**

If the source DynamoDB table is encrypted using customer managed AWS KMS key, you will need to add the following policy on your KMS key. This policy allows Amazon Redshift to be able to export data from your encrypted table using your KMS key.

```
{
```

```
    "Sid": "AllowRedshiftDecryptSourceTable",
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "redshift.amazonaws.com"
        ]
    },
    "Action": "kms:Decrypt",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "<account>"
        },
        "ArnEquals": {
            "aws:SourceArn": "arn:aws:redshift:<region>:<account>:integration:*"
        }
    }
}
```

You can also follow the steps on Getting started with zero-ETL integrations in the Amazon Redshift management guide to configure the permissions of the Amazon Redshift namespace.

Limitations when using DynamoDB zero-ETL integrations with Amazon Redshift

The following general limitations apply to the current release of this integration. These limitations can change in subsequent releases.

> **Note**
>
> In addition to the limitations below, also review the general considerations when using zero-ETL integrations see Considerations when using zero-ETL integrations with Amazon Redshift in the *Amazon Redshift Management Guide*.

- The DynamoDB table and Amazon Redshift cluster need to be in the same Region.
- The source DynamoDB table must be encrypted with either an Amazon-owned or Customer-managed AWS KMS key. Amazon managed encryption is not supported for the source DynamoDB table.

Creating a DynamoDB zero-ETL integration with Amazon Redshift

Before creating a zero-ETL integration, you must first set up your source DynamoDB table and then the target Amazon Redshift data warehouse.

Step 1: Configuring a source DynamoDB table

To create a zero-ETL integration with Amazon Redshift, you need to enable point-in-time recovery (PITR) on your table. If you do not have PITR turned on, the console can fix this for you during the integration setup process. For details on how to enable PITR, see Point-in-time recovery.

Step 2: Creating an Amazon Redshift data warehouse

If you don't already have an Amazon Redshift data warehouse, you can create one. To create an Amazon Redshift Serverless workgroup, see Creating a workgroup with a namespace. To create an Amazon Redshift cluster, see Creating a cluster.

The target Amazon Redshift workgroup or cluster must have the enable_case_sensitive_identifier parameter turned on for the integration to be successful. For more information on enabling case sensitivity, see Turn on case sensitivity for your data warehouse in the Amazon Redshift management guide.

After the Amazon Redshift workgroup or cluster setup is complete, you need to configure your data warehouse. See Zero-ETL integrations in the Amazon Redshift Management Guide for more information.

Step 3: Creating a DynamoDB zero-ETL integration

Before you create a zero-ETL integration, make sure to complete the tasks in the section titled Prerequisites before creating a DynamoDB zero-ETL integration with Amazon Redshift. Creating an integration between DynamoDB and Amazon Redshift is a two-step process. First create an integration from the DynamoDB, and then attach a Amazon Redshift database to this newly created integration.

Create a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.
2. In the navigation pane, choose **Integrations**.

3. Select **Create zero-ETL integration** and choose **Amazon Redshift**.
4. This will take you to the **Amazon Redshift console**. To continue with the procedure, see the **DynamoDB section** in Create a zero-ETL integration for DynamoDB.

Viewing DynamoDB zero-ETL integrations with Amazon Redshift

You can view the details of a zero-ETL integration to see its configuration information and current status.

To view the details of a zero-ETL integration in the Amazon DynamoDB console:

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.
2. In the DynamoDB console, choose **Integrations**.
3. In the **Zero-ETL integration** pane, select the zero-ETL integration you want to view.

To view the details of a zero-ETL integration in the Amazon Redshift console:

1. Sign in to the AWS Management Console and open the Amazon Redshift console at https://console.aws.amazon.com/redshiftv2.
2. Follow the steps at Viewing zero-ETL integrations.

> **Note**
>
> The possible statuses of a zero-ETL integration with Amazon Redshift are listed in Viewing zero-ETL integrations in the *Amazon Redshift Management Guide*.

Deleting DynamoDB zero-ETL integrations with Amazon Redshift

When you delete a zero-ETL integration, your data isn't deleted from DynamoDB or Amazon Redshift, but DynamoDB stops sending data from your source table to the Amazon Redshift target.

To delete a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.

2. In the DynamoDB console, choose **Integrations**.
3. In the **Zero-ETL integration** pane, select the zero-ETL integration you want to delete.
4. Choose **Manage**. This will take you to the integration details page.
5. To confirm the deletion, choose **Delete**.

Loading data from DynamoDB into Amazon Redshift with the COPY command

Amazon Redshift works with Amazon DynamoDB with advanced business intelligence capabilities and a powerful SQL-based interface. When you copy data from a DynamoDB table into Amazon Redshift, you can perform complex data analysis queries on that data, including joins with other tables in your Amazon Redshift cluster.

In terms of provisioned throughput, a copy operation from a DynamoDB table counts against that table's read capacity. After the data is copied, your SQL queries in Amazon Redshift do not affect DynamoDB in any way. This is because your queries act upon a copy of the data from DynamoDB, rather than upon DynamoDB itself.

Before you can load data from a DynamoDB table, you must first create an Amazon Redshift table to serve as the destination for the data. Keep in mind that you are copying data from a NoSQL environment into a SQL environment, and that there are certain rules in one environment that do not apply in the other. Here are some of the differences to consider:

- DynamoDB table names can contain up to 255 characters, including '.' (dot) and '-' (dash) characters, and are case-sensitive. Amazon Redshift table names are limited to 127 characters, cannot contain dots or dashes and are not case-sensitive. In addition, table names cannot conflict with any Amazon Redshift reserved words.
- DynamoDB does not support the SQL concept of NULL. You need to specify how Amazon Redshift interprets empty or blank attribute values in DynamoDB, treating them either as NULLs or as empty fields.
- DynamoDB data types do not correspond directly with those of Amazon Redshift. You need to make sure that each column in the Amazon Redshift table is of the correct data type and size to accommodate the data from DynamoDB.

Here is an example COPY command from Amazon Redshift SQL:

```
copy favoritemovies from 'dynamodb://my-favorite-movies-table'
credentials 'aws_access_key_id=<Your-Access-Key-ID>;aws_secret_access_key=<Your-Secret-
Access-Key>'
readratio 50;
```

In this example, the source table in DynamoDB is `my-favorite-movies-table`. The target table in Amazon Redshift is `favoritemovies`. The `readratio 50` clause regulates the percentage of provisioned throughput that is consumed; in this case, the COPY command will use no more than 50 percent of the read capacity units provisioned for `my-favorite-movies-table`. We highly recommend setting this ratio to a value less than the average unused provisioned throughput.

For detailed instructions on loading data from DynamoDB into Amazon Redshift, refer to the following sections in the *Amazon Redshift Database Developer Guide*:

- Loading data from a DynamoDB table
- The COPY command
- COPY examples

Processing DynamoDB data with Apache Hive on Amazon EMR

Amazon DynamoDB is integrated with Apache Hive, a data warehousing application that runs on Amazon EMR. Hive can read and write data in DynamoDB tables, allowing you to:

- Query live DynamoDB data using a SQL-like language (HiveQL).
- Copy data from a DynamoDB table to an Amazon S3 bucket, and vice-versa.
- Copy data from a DynamoDB table into Hadoop Distributed File System (HDFS), and vice-versa.
- Perform join operations on DynamoDB tables.

Topics

- Overview
- Tutorial: Working with Amazon DynamoDB and Apache Hive
- Creating an external table in Hive
- Processing HiveQL statements
- Querying data in DynamoDB

- Copying data to and from Amazon DynamoDB
- Performance tuning

Overview

Amazon EMR is a service that makes it easy to quickly and cost-effectively process vast amounts of data. To use Amazon EMR, you launch a managed cluster of Amazon EC2 instances running the Hadoop open source framework. *Hadoop* is a distributed application that implements the MapReduce algorithm, where a task is mapped to multiple nodes in the cluster. Each node processes its designated work, in parallel with the other nodes. Finally, the outputs are reduced on a single node, yielding the final result.

You can choose to launch your Amazon EMR cluster so that it is persistent or transient:

- A *persistent* cluster runs until you shut it down. Persistent clusters are ideal for data analysis, data warehousing, or any other interactive use.
- A *transient* cluster runs long enough to process a job flow, and then shuts down automatically. Transient clusters are ideal for periodic processing tasks, such as running scripts.

For information about Amazon EMR architecture and administration, see the Amazon EMR Management Guide.

When you launch an Amazon EMR cluster, you specify the initial number and type of Amazon EC2 instances. You also specify other distributed applications (in addition to Hadoop itself) that you want to run on the cluster. These applications include Hue, Mahout, Pig, Spark, and more.

For information about applications for Amazon EMR, see the Amazon EMR Release Guide.

Depending on the cluster configuration, you might have one or more of the following node types:

- Leader node — Manages the cluster, coordinating the distribution of the MapReduce executable and subsets of the raw data, to the core and task instance groups. It also tracks the status of each task performed and monitors the health of the instance groups. There is only one leader node in a cluster.
- Core nodes — Runs MapReduce tasks and stores data using the Hadoop Distributed File System (HDFS).
- Task nodes (optional) — Runs MapReduce tasks.

Tutorial: Working with Amazon DynamoDB and Apache Hive

In this tutorial, you will launch an Amazon EMR cluster, and then use Apache Hive to process data stored in a DynamoDB table.

Hive is a data warehouse application for Hadoop that allows you to process and analyze data from multiple sources. Hive provides a SQL-like language, *HiveQL*, that lets you work with data stored locally in the Amazon EMR cluster or in an external data source (such as Amazon DynamoDB).

For more information, see to the Hive Tutorial.

Topics

- Before you begin
- Step 1: Create an Amazon EC2 key pair
- Step 2: Launch an Amazon EMR cluster
- Step 3: Connect to the Leader node
- Step 4: Load data into HDFS
- Step 5: Copy data to DynamoDB
- Step 6: Query the data in the DynamoDB table
- Step 7: (Optional) clean up

Before you begin

For this tutorial, you will need the following:

- An AWS account. If you do not have one, see Sign up for an AWS account.
- An SSH client (Secure Shell). You use the SSH client to connect to the leader node of the Amazon EMR cluster and run interactive commands. SSH clients are available by default on most Linux, Unix, and Mac OS X installations. Windows users can download and install the PuTTY client, which has SSH support.

Next step

Step 1: Create an Amazon EC2 key pair

Step 1: Create an Amazon EC2 key pair

In this step, you will create the Amazon EC2 key pair you need to connect to an Amazon EMR leader node and run Hive commands.

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose a region (for example, `US West (Oregon)`). This should be the same region in which your DynamoDB table is located.
3. In the navigation pane, choose **Key Pairs**.
4. Choose **Create Key Pair**.
5. In **Key pair name**, type a name for your key pair (for example, `mykeypair`), and then choose **Create**.
6. Download the private key file. The file name will end with `.pem` (such as `mykeypair.pem`). Keep this private key file in a safe place. You will need it to access any Amazon EMR cluster that you launch with this key pair.

   > **Important**
   >
   > If you lose the key pair, you cannot connect to the leader node of your Amazon EMR cluster.

   For more information about key pairs, see Amazon EC2 Key Pairs in the *Amazon EC2 User Guide*.

Next step

Step 2: Launch an Amazon EMR cluster

Step 2: Launch an Amazon EMR cluster

In this step, you will configure and launch an Amazon EMR cluster. Hive and a storage handler for DynamoDB will already be installed on the cluster.

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create Cluster**.

3. On the **Create Cluster - Quick Options** page, do the following:

   a. In **Cluster name**, type a name for your cluster (for example: `My EMR cluster`).

   b. In **EC2 key pair**, choose the key pair you created earlier.

   Leave the other settings at their defaults.

4. Choose **Create cluster**.

It will take several minutes to launch your cluster. You can use the **Cluster Details** page in the Amazon EMR console to monitor its progress.

When the status changes to `Waiting`, the cluster is ready for use.

Cluster log files and Amazon S3

An Amazon EMR cluster generates log files that contain information about the cluster status and debugging information. The default settings for **Create Cluster - Quick Options** include setting up Amazon EMR logging.

If one does not already exist, the AWS Management Console creates an Amazon S3 bucket. The bucket name is `aws-logs-`*`account-id`*`-`*`region`*, where *`account-id`* is your AWS account number and *`region`* is the region in which you launched the cluster (for example, `aws-logs-123456789012-us-west-2`).

> **Note**
>
> You can use the Amazon S3 console to view the log files. For more information, see View Log Files in the *Amazon EMR Management Guide*.

You can use this bucket for purposes in addition to logging. For example, you can use the bucket as a location for storing a Hive script or as a destination when exporting data from Amazon DynamoDB to Amazon S3.

Next step

Step 3: Connect to the Leader node

Step 3: Connect to the Leader node

When the status of your Amazon EMR cluster changes to `Waiting`, you will be able to connect to the leader node using SSH and perform command line operations.

1. In the Amazon EMR console, choose your cluster's name to view its status.
2. On the **Cluster Details** page, find the **Leader public DNS** field. This is the public DNS name for the leader node of your Amazon EMR cluster.
3. To the right of the DNS name, choose the **SSH** link.
4. Follow the instructions in **Connect to the Leader Node Using SSH** .

   Depending on your operating system, choose the **Windows** tab or the **Mac/Linux** tab, and follow the instructions for connecting to the leader node.

After you connect to the leader node using either SSH or PuTTY, you should see a command prompt similar to the following:

```
[hadoop@ip-192-0-2-0 ~]$
```

Next step

Step 4: Load data into HDFS

Step 4: Load data into HDFS

In this step, you will copy a data file into Hadoop Distributed File System (HDFS), and then create an external Hive table that maps to the data file.

Download the sample data

1. Download the sample data archive (`features.zip`):

   ```
   wget https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
   features.zip
   ```

2. Extract the `features.txt` file from the archive:

   ```
   unzip features.zip
   ```

3. View the first few lines of the `features.txt` file:

```
head features.txt
```

The result should look similar to this:

```
1535908|Big Run|Stream|WV|38.6370428|-80.8595469|794
875609|Constable Hook|Cape|NJ|40.657881|-74.0990309|7
1217998|Gooseberry Island|Island|RI|41.4534361|-71.3253284|10
26603|Boone Moore Spring|Spring|AZ|34.0895692|-111.410065|3681
1506738|Missouri Flat|Flat|WA|46.7634987|-117.0346113|2605
1181348|Minnow Run|Stream|PA|40.0820178|-79.3800349|1558
1288759|Hunting Creek|Stream|TN|36.343969|-83.8029682|1024
533060|Big Charles Bayou|Bay|LA|29.6046517|-91.9828654|0
829689|Greenwood Creek|Stream|NE|41.596086|-103.0499296|3671
541692|Button Willow Island|Island|LA|31.9579389|-93.0648847|98
```

The `features.txt` file contains a subset of data from the United States Board on Geographic Names (http://geonames.usgs.gov/domestic/download_data.htm). The fields in each line represent the following:

- Feature ID (unique identifier)
- Name
- Class (lake; forest; stream; and so on)
- State
- Latitude (degrees)
- Longitude (degrees)
- Height (in feet)

4. At the command prompt, enter the following command:

```
hive
```

The command prompt changes to this: `hive>`

5. Enter the following HiveQL statement to create a native Hive table:

```
CREATE TABLE hive_features
    (feature_id             BIGINT,
```

```
    feature_name            STRING ,
    feature_class           STRING ,
    state_alpha             STRING,
    prim_lat_dec            DOUBLE ,
    prim_long_dec           DOUBLE ,
    elev_in_ft              BIGINT)
    ROW FORMAT DELIMITED
    FIELDS TERMINATED BY '|'
    LINES TERMINATED BY '\n';
```

6. Enter the following HiveQL statement to load the table with data:

```
LOAD DATA
LOCAL
INPATH './features.txt'
OVERWRITE
INTO TABLE hive_features;
```

7. You now have a native Hive table populated with data from the `features.txt` file. To verify, enter the following HiveQL statement:

```
SELECT state_alpha, COUNT(*)
FROM hive_features
GROUP BY state_alpha;
```

   The output should show a list of states and the number of geographic features in each.

Next step

Step 5: Copy data to DynamoDB

Step 5: Copy data to DynamoDB

In this step, you will copy data from the Hive table (`hive_features`) to a new table in DynamoDB.

1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. Choose **Create Table**.
3. On the **Create DynamoDB table** page, do the following:
   a. In **Table**, type **`Features`**.
   b. For **Primary key**, in the **Partition key** field, type **`Id`**. Set the data type to **Number**.

Clear **Use Default Settings**. For **Provisioned Capacity**, type the following:

- **Read Capacity Units**—10
- **Write Capacity Units**—10

Choose **Create**.

4. At the Hive prompt, enter the following HiveQL statement:

```
CREATE EXTERNAL TABLE ddb_features
    (feature_id   BIGINT,
    feature_name  STRING,
    feature_class STRING,
    state_alpha   STRING,
    prim_lat_dec  DOUBLE,
    prim_long_dec DOUBLE,
    elev_in_ft    BIGINT)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES(
    "dynamodb.table.name" = "Features",

 "dynamodb.column.mapping"="feature_id:Id,feature_name:Name,feature_class:Class,state_alpha
);
```

You have now established a mapping between Hive and the Features table in DynamoDB.

5. Enter the following HiveQL statement to import data to DynamoDB:

```
INSERT OVERWRITE TABLE ddb_features
SELECT
    feature_id,
    feature_name,
    feature_class,
    state_alpha,
    prim_lat_dec,
    prim_long_dec,
    elev_in_ft
FROM hive_features;
```

Hive will submit a MapReduce job, which will be processed by your Amazon EMR cluster. It will take several minutes to complete the job.

6. Verify that the data has been loaded into DynamoDB:

   a. In the DynamoDB console navigation pane, choose **Tables**.

   b. Choose the Features table, and then choose the **Items** tab to view the data.

Next step

Step 6: Query the data in the DynamoDB table

Step 6: Query the data in the DynamoDB table

In this step, you will use HiveQL to query the Features table in DynamoDB. Try the following Hive queries:

1. All of the feature types (`feature_class`) in alphabetical order:

```
SELECT DISTINCT feature_class
FROM ddb_features
ORDER BY feature_class;
```

2. All of the lakes that begin with the letter "M":

```
SELECT feature_name, state_alpha
FROM ddb_features
WHERE feature_class = 'Lake'
AND feature_name LIKE 'M%'
ORDER BY feature_name;
```

3. States with at least three features higher than a mile (5,280 feet):

```
SELECT state_alpha, feature_class, COUNT(*)
FROM ddb_features
WHERE elev_in_ft > 5280
GROUP by state_alpha, feature_class
HAVING COUNT(*) >= 3
ORDER BY state_alpha, feature_class;
```

Next step

Step 7: (Optional) clean up

Step 7: (Optional) clean up

Now that you have completed the tutorial, you can continue reading this section to learn more about working with DynamoDB data in Amazon EMR. You might decide to keep your Amazon EMR cluster up and running while you do this.

If you don't need the cluster anymore, you should terminate it and remove any associated resources. This will help you avoid being charged for resources you don't need.

1. Terminate the Amazon EMR cluster:
   a. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
   b. Choose the Amazon EMR cluster, choose **Terminate**, and then confirm.
2. Delete the Features table in DynamoDB:
   a. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
   b. In the navigation pane, choose **Tables**.
   c. Choose the Features table. From the **Actions** menu, choose **Delete Table**.
3. Delete the Amazon S3 bucket containing the Amazon EMR log files:
   a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
   b. From the list of buckets, choose `aws-logs-` *`accountID`*`-`*`region`*, where *`accountID`* is your AWS account number and *`region`* is the region in which you launched the cluster.
   c. From the **Action** menu, choose **Delete**.

Creating an external table in Hive

In Tutorial: Working with Amazon DynamoDB and Apache Hive, you created an external Hive table that mapped to a DynamoDB table. When you issued HiveQL statements against the external table, the read and write operations were passed through to the DynamoDB table.

You can think of an external table as a pointer to a data source that is managed and stored elsewhere. In this case, the underlying data source is a DynamoDB table. (The table must already exist. You cannot create, update, or delete a DynamoDB table from within Hive.) You use the `CREATE EXTERNAL TABLE` statement to create the external table. After that, you can use HiveQL to work with data in DynamoDB, as if that data were stored locally within Hive.

> **Note**
>
> You can use INSERT statements to insert data into an external table and SELECT statements to select data from it. However, you cannot use UPDATE or DELETE statements to manipulate data in the table.

If you no longer need the external table, you can remove it using the DROP TABLE statement. In this case, DROP TABLE only removes the external table in Hive. It does not affect the underlying DynamoDB table or any of its data.

Topics

- CREATE EXTERNAL TABLE syntax
- Data type mappings

CREATE EXTERNAL TABLE syntax

The following shows the HiveQL syntax for creating an external Hive table that maps to a DynamoDB table:

```
CREATE EXTERNAL TABLE hive_table

 (hive_column1_name hive_column1_datatype, hive_column2_name hive_column2_datatype...)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES (
    "dynamodb.table.name" = "dynamodb_table",
    "dynamodb.column.mapping" =
 "hive_column1_name:dynamodb_attribute1_name,hive_column2_name:dynamodb_attribute2_name..."
);
```

Line 1 is the start of the CREATE EXTERNAL TABLE statement, where you provide the name of the Hive table (*hive_table*) you want to create.

Line 2 specifies the columns and data types for *hive_table*. You need to define columns and data types that correspond to the attributes in the DynamoDB table.

Line 3 is the STORED BY clause, where you specify a class that handles data management between the Hive and the DynamoDB table. For DynamoDB, STORED BY should be set to `'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'`.

Line 4 is the start of the `TBLPROPERTIES` clause, where you define the following parameters for `DynamoDBStorageHandler`:

- `dynamodb.table.name`—the name of the DynamoDB table.
- `dynamodb.column.mapping`—pairs of column names in the Hive table and their corresponding attributes in the DynamoDB table. Each pair is of the form *hive_column_name:dynamodb_attribute_name*, and the pairs are separated by commas.

Note the following:

- The name of the Hive table name does not have to be the same as the DynamoDB table name.
- The Hive table column names do not have to be the same as those in the DynamoDB table.
- The table specified by `dynamodb.table.name` must exist in DynamoDB.
- For `dynamodb.column.mapping`:
  - You must map the key schema attributes for the DynamoDB table. This includes the partition key and the sort key (if present).
  - You do not have to map the non-key attributes of the DynamoDB table. However, you will not see any data from those attributes when you query the Hive table.
  - If the data types of a Hive table column and a DynamoDB attribute are incompatible, you will see `NULL` in these columns when you query the Hive table.

> **Note**
>
> The `CREATE EXTERNAL TABLE` statement does not perform any validation on the `TBLPROPERTIES` clause. The values you provide for `dynamodb.table.name` and `dynamodb.column.mapping` are only evaluated by the `DynamoDBStorageHandler` class when you attempt to access the table.

Data type mappings

The following table shows DynamoDB data types and compatible Hive data types:

DynamoDB Data Type	Hive Data Type
String	`STRING`
Number	`BIGINT` or `DOUBLE`
Binary	`BINARY`
String Set	`ARRAY<STRING>`
Number Set	`ARRAY<BIGINT>` or `ARRAY<DOUBLE>`
Binary Set	`ARRAY<BINARY>`

Note

The following DynamoDB data types are not supported by the `DynamoDBStorageHandler` class, so they cannot be used with `dynamodb.column.mapping`:

- Map
- List
- Boolean
- Null

However, if you need to work with these data types, you can create a single entity called `item` that represents the entire DynamoDB item as a map of strings for both keys and values in the map. For more information, see Copying data without a column mapping

If you want to map a DynamoDB attribute of type Number, you must choose an appropriate Hive type:

- The Hive `BIGINT` type is for 8-byte signed integers. It is the same as the `long` data type in Java.
- The Hive `DOUBLE` type is for 8-bit double precision floating point numbers. It is the same as the `double` type in Java.

If you have numeric data stored in DynamoDB that has a higher precision than the Hive data type you choose, then accessing the DynamoDB data could cause a loss of precision.

If you export data of type Binary from DynamoDB to (Amazon S3) or HDFS, the data is stored as a Base64-encoded string. If you import data from Amazon S3 or HDFS into the DynamoDB Binary type, you must make sure the data is encoded as a Base64 string.

Processing HiveQL statements

Hive is an application that runs on Hadoop, which is a batch-oriented framework for running MapReduce jobs. When you issue a HiveQL statement, Hive determines whether it can return the results immediately or whether it must submit a MapReduce job.

For example, consider the *ddb_features* table (from Tutorial: Working with Amazon DynamoDB and Apache Hive). The following Hive query prints state abbreviations and the number of summits in each:

```
SELECT state_alpha, count(*)
FROM ddb_features
WHERE feature_class = 'Summit'
GROUP BY state_alpha;
```

Hive does not return the results immediately. Instead, it submits a MapReduce job, which is processed by the Hadoop framework. Hive will wait until the job is complete before it shows the results from the query:

```
AK  2
AL  2
AR  2
AZ  3
CA  7
CO  2
CT  2
ID  1
KS  1
ME  2
MI  1
MT  3
NC  1
NE  1
NM  1
```

```
NY  2
OR  5
PA  1
TN  1
TX  1
UT  4
VA  1
VT  2
WA  2
WY  3
Time taken: 8.753 seconds, Fetched: 25 row(s)
```

Monitoring and canceling jobs

When Hive launches a Hadoop job, it prints output from that job. The job completion status is updated as the job progresses. In some cases, the status might not be updated for a long time. (This can happen when you are querying a large DynamoDB table that has a low provisioned read capacity setting.)

If you need to cancel the job before it is complete, you can type **`Ctrl+C`** at any time.

Querying data in DynamoDB

The following examples show some ways that you can use HiveQL to query data stored in DynamoDB.

These examples refer to the *ddb_features* table in the tutorial (Step 5: Copy data to DynamoDB).

Topics

- Using aggregate functions
- Using the GROUP BY and HAVING clauses
- Joining two DynamoDB tables
- Joining tables from different sources

Using aggregate functions

HiveQL provides built-in functions for summarizing data values. For example, you can use the `MAX` function to find the largest value for a selected column. The following example returns the elevation of the highest feature in the state of Colorado.

```
SELECT MAX(elev_in_ft)
FROM ddb_features
WHERE state_alpha = 'CO';
```

Using the GROUP BY and HAVING clauses

You can use the `GROUP BY` clause to collect data across multiple records. This is often used with an aggregate function such as `SUM`, `COUNT`, `MIN`, or `MAX`. You can also use the `HAVING` clause to discard any results that do not meet certain criteria.

The following example returns a list of the highest elevations from states that have more than five features in the *ddb_features* table.

```
SELECT state_alpha, max(elev_in_ft)
FROM ddb_features
GROUP BY state_alpha
HAVING count(*) >= 5;
```

Joining two DynamoDB tables

The following example maps another Hive table (*east_coast_states*) to a table in DynamoDB. The `SELECT` statement is a join across these two tables. The join is computed on the cluster and returned. The join does not take place in DynamoDB.

Consider a DynamoDB table named EastCoastStates that contains the following data:

```
StateName       StateAbbrev

Maine           ME
New Hampshire   NH
Massachusetts   MA
Rhode Island    RI
Connecticut     CT
New York        NY
New Jersey      NJ
Delaware        DE
Maryland        MD
Virginia        VA
North Carolina  NC
South Carolina  SC
Georgia         GA
```

```
Florida         FL
```

Let's assume the table is available as a Hive external table named east_coast_states:

```
CREATE EXTERNAL TABLE ddb_east_coast_states (state_name STRING, state_alpha STRING)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "EastCoastStates",
"dynamodb.column.mapping" = "state_name:StateName,state_alpha:StateAbbrev");
```

The following join returns the states on the East Coast of the United States that have at least three features:

```
SELECT ecs.state_name, f.feature_class, COUNT(*)
FROM ddb_east_coast_states ecs
JOIN ddb_features f on ecs.state_alpha = f.state_alpha
GROUP BY ecs.state_name, f.feature_class
HAVING COUNT(*) >= 3;
```

Joining tables from different sources

In the following example, s3_east_coast_states is a Hive table associated with a CSV file stored in Amazon S3. The *ddb_features* table is associated with data in DynamoDB. The following example joins these two tables, returning the geographic features from states whose names begin with "New."

```
create external table s3_east_coast_states (state_name STRING, state_alpha STRING)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
LOCATION 's3://bucketname/path/subpath/';
```

```
SELECT ecs.state_name, f.feature_name, f.feature_class
FROM s3_east_coast_states ecs
JOIN ddb_features f
ON ecs.state_alpha = f.state_alpha
WHERE ecs.state_name LIKE 'New%';
```

Copying data to and from Amazon DynamoDB

In the Tutorial: Working with Amazon DynamoDB and Apache Hive, you copied data from a native Hive table into an external DynamoDB table, and then queried the external DynamoDB table. The

table is external because it exists outside of Hive. Even if you drop the Hive table that maps to it, the table in DynamoDB is not affected.

Hive is an excellent solution for copying data among DynamoDB tables, Amazon S3 buckets, native Hive tables, and Hadoop Distributed File System (HDFS). This section provides examples of these operations.

Topics

- Copying data between DynamoDB and a native Hive table
- Copying data between DynamoDB and Amazon S3
- Copying data between DynamoDB and HDFS
- Using data compression
- Reading non-printable UTF-8 character data

Copying data between DynamoDB and a native Hive table

If you have data in a DynamoDB table, you can copy the data to a native Hive table. This will give you a snapshot of the data, as of the time you copied it.

You might decide to do this if you need to perform many HiveQL queries, but do not want to consume provisioned throughput capacity from DynamoDB. Because the data in the native Hive table is a copy of the data from DynamoDB, and not "live" data, your queries should not expect that the data is up-to-date.

> **Note**
>
> The examples in this section are written with the assumption you followed the steps in Tutorial: Working with Amazon DynamoDB and Apache Hive and have an external table in DynamoDB named *ddb_features*.

Example From DynamoDB to native Hive table

You can create a native Hive table and populate it with data from *ddb_features*, like this:

```
CREATE TABLE features_snapshot AS
SELECT * FROM ddb_features;
```

You can then refresh the data at any time:

```
INSERT OVERWRITE TABLE features_snapshot
SELECT * FROM ddb_features;
```

In these examples, the subquery `SELECT * FROM ddb_features` will retrieve all of the data from *ddb_features*. If you only want to copy a subset of the data, you can use a `WHERE` clause in the subquery.

The following example creates a native Hive table, containing only some of the attributes for lakes and summits:

```
CREATE TABLE lakes_and_summits AS
SELECT feature_name, feature_class, state_alpha
FROM ddb_features
WHERE feature_class IN ('Lake','Summit');
```

Example From native Hive table to DynamoDB

Use the following HiveQL statement to copy the data from the native Hive table to *ddb_features*:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM features_snapshot;
```

Copying data between DynamoDB and Amazon S3

If you have data in a DynamoDB table, you can use Hive to copy the data to an Amazon S3 bucket.

You might do this if you want to create an archive of data in your DynamoDB table. For example, suppose you have a test environment where you need to work with a baseline set of test data in DynamoDB. You can copy the baseline data to an Amazon S3 bucket, and then run your tests. Afterward, you can reset the test environment by restoring the baseline data from the Amazon S3 bucket to DynamoDB.

If you worked through Tutorial: Working with Amazon DynamoDB and Apache Hive, then you already have an Amazon S3 bucket that contains your Amazon EMR logs. You can use this bucket for the examples in this section, if you know the root path for the bucket:

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.

2. For **Name**, choose your cluster.
3. The URI is listed in **Log URI** under **Configuration Details**.
4. Make a note of the root path of the bucket. The naming convention is:

   `s3://aws-logs-`*`accountID`*`-`*`region`*

   where *`accountID`* is your AWS account ID and region is the AWS region for the bucket.

> **Note**
>
> These examples use a subpath within the bucket, as in this example: `s3://aws-logs-123456789012-us-west-2/hive-test`

The following procedures are written with the assumption you followed the steps in the tutorial and have an external table in DynamoDB named *ddb_features*.

Topics

- Copying data using the Hive default format
- Copying data with a user-specified format
- Copying data without a column mapping
- Viewing the data in Amazon S3

Copying data using the Hive default format

Example From DynamoDB to Amazon S3

Use an `INSERT OVERWRITE` statement to write directly to Amazon S3.

```
INSERT OVERWRITE DIRECTORY 's3://aws-logs-123456789012-us-west-2/hive-test'
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANM^A32.3564729^A-108.33004616135
1178153^AJones Run^AStream^APA^A41.2120086^A-79.25920781260
253838^ASentinel Dome^ASummit^ACA^A37.7229821^A-119.584338133
```

```
264054^ANeversweet Gulch^AValley^ACA^A41.6565269^A-122.83614322900
115905^AChacaloochee Bay^ABay^AAL^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as **^A**.

Example From Amazon S3 to DynamoDB

1. Create an external table pointing to the unformatted data in Amazon S3.

```
CREATE EXTERNAL TABLE s3_features_unformatted
    (feature_id       BIGINT,
    feature_name      STRING ,
    feature_class     STRING ,
    state_alpha       STRING,
    prim_lat_dec      DOUBLE ,
    prim_long_dec     DOUBLE ,
    elev_in_ft        BIGINT)
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data to DynamoDB.

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM s3_features_unformatted;
```

Copying data with a user-specified format

If you want to specify your own field separator character, you can create an external table that maps to the Amazon S3 bucket. You might use this technique for creating data files with comma-separated values (CSV).

Example From DynamoDB to Amazon S3

1. Create a Hive external table that maps to Amazon S3. When you do this, make sure that the data types are consistent with those of the DynamoDB external table.

```
CREATE EXTERNAL TABLE s3_features_csv
    (feature_id       BIGINT,
    feature_name      STRING,
    feature_class     STRING,
    state_alpha       STRING,
    prim_lat_dec      DOUBLE,
```

```
    prim_long_dec     DOUBLE,
    elev_in_ft        BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data from DynamoDB.

```
INSERT OVERWRITE TABLE s3_features_csv
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900
115905,Chacaloochee Bay,Bay,AL,30.6979676,-87.9738853,0
```

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM s3_features_csv;
```

Copying data without a column mapping

You can copy data from DynamoDB in a raw format and write it to Amazon S3 without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in Amazon S3.

Example From DynamoDB to Amazon S3

1. Create an external table associated with your DynamoDB table. (There is no `dynamodb.column.mapping` in this HiveQL statement.)

```
CREATE EXTERNAL TABLE ddb_features_no_mapping
```

```
    (item MAP<STRING, STRING>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "Features");
```

2. Create another external table associated with your Amazon S3 bucket.

```
CREATE EXTERNAL TABLE s3_features_no_mapping
    (item MAP<STRING, STRING>)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY '\t'
LINES TERMINATED BY '\n'
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

3. Copy the data from DynamoDB to Amazon S3.

```
INSERT OVERWRITE TABLE s3_features_no_mapping
SELECT * FROM ddb_features_no_mapping;
```

The data file in Amazon S3 looks like this:

```
Name^C{"s":"Soldiers Farewell

Each field begins with an STX character (start of text, 0x02) and ends with an ETX character (end of text, 0x03). In the file, STX appears as **^B** and ETX appears as **^C**.

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```
INSERT OVERWRITE TABLE ddb_features_no_mapping
```

```
SELECT * FROM s3_features_no_mapping;
```

Viewing the data in Amazon S3

If you use SSH to connect to the leader node, you can use the AWS Command Line Interface (AWS CLI) to access the data that Hive wrote to Amazon S3.

The following steps are written with the assumption you have copied data from DynamoDB to Amazon S3 using one of the procedures in this section.

1. If you are currently at the Hive command prompt, exit to the Linux command prompt.

   ```
   hive> exit;
   ```

2. List the contents of the hive-test directory in your Amazon S3 bucket. (This is where Hive copied the data from DynamoDB.)

   ```
   aws s3 ls s3://aws-logs-123456789012-us-west-2/hive-test/
   ```

   The response should look similar to this:

   ```
   2016-11-01 23:19:54 81983 000000_0
   ```

   The file name (*000000_0*) is system-generated.

3. (Optional) You can copy the data file from Amazon S3 to the local file system on the leader node. After you do this, you can use standard Linux command line utilities to work with the data in the file.

   ```
   aws s3 cp s3://aws-logs-123456789012-us-west-2/hive-test/000000_0 .
   ```

   The response should look similar to this:

   ```
   download: s3://aws-logs-123456789012-us-west-2/hive-test/000000_0
   to ./000000_0
   ```

   > **Note**
   >
   > The local file system on the leader node has limited capacity. Do not use this command with files that are larger than the available space in the local file system.

Copying data between DynamoDB and HDFS

If you have data in a DynamoDB table, you can use Hive to copy the data to the Hadoop Distributed File System (HDFS).

You might do this if you are running a MapReduce job that requires data from DynamoDB. If you copy the data from DynamoDB into HDFS, Hadoop can process it, using all of the available nodes in the Amazon EMR cluster in parallel. When the MapReduce job is complete, you can then write the results from HDFS to DDB.

In the following examples, Hive will read from and write to the following HDFS directory: `/user/hadoop/hive-test`

> **Note**
>
> The examples in this section are written with the assumption you followed the steps in Tutorial: Working with Amazon DynamoDB and Apache Hive and you have an external table in DynamoDB named *ddb_features*.

Topics

- Copying data using the Hive default format
- Copying data with a user-specified format
- Copying data without a column mapping
- Accessing the data in HDFS

Copying data using the Hive default format

Example From DynamoDB to HDFS

Use an `INSERT OVERWRITE` statement to write directly to HDFS.

```
INSERT OVERWRITE DIRECTORY 'hdfs:///user/hadoop/hive-test'
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANM^A32.3564729^A-108.33004616135
```

```
1178153^AJones Run^AStream^APA^A41.2120086^A-79.25920781260
253838^ASentinel Dome^ASummit^ACA^A37.7229821^A-119.584338133
264054^ANeversweet Gulch^AValley^ACA^A41.6565269^A-122.83614322900
115905^AChacaloochee Bay^ABay^AAL^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as **^A**.

Example From HDFS to DynamoDB

1. Create an external table that maps to the unformatted data in HDFS.

   ```
   CREATE EXTERNAL TABLE hdfs_features_unformatted
       (feature_id       BIGINT,
       feature_name      STRING ,
       feature_class     STRING ,
       state_alpha       STRING,
       prim_lat_dec      DOUBLE ,
       prim_long_dec     DOUBLE ,
       elev_in_ft        BIGINT)
   LOCATION 'hdfs:///user/hadoop/hive-test';
   ```

2. Copy the data to DynamoDB.

   ```
   INSERT OVERWRITE TABLE ddb_features
   SELECT * FROM hdfs_features_unformatted;
   ```

Copying data with a user-specified format

If you want to use a different field separator character, you can create an external table that maps to the HDFS directory. You might use this technique for creating data files with comma-separated values (CSV).

Example From DynamoDB to HDFS

1. Create a Hive external table that maps to HDFS. When you do this, ensure that the data types are consistent with those of the DynamoDB external table.

   ```
   CREATE EXTERNAL TABLE hdfs_features_csv
       (feature_id       BIGINT,
       feature_name      STRING ,
       feature_class     STRING ,
   ```

```
    state_alpha       STRING,
    prim_lat_dec      DOUBLE ,
    prim_long_dec     DOUBLE ,
    elev_in_ft        BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 'hdfs:///user/hadoop/hive-test';
```

2. Copy the data from DynamoDB.

```
INSERT OVERWRITE TABLE hdfs_features_csv
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900
115905,Chacaloochee Bay,Bay,AL,30.6979676,-87.9738853,0
```

Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM hdfs_features_csv;
```

Copying data without a column mapping

You can copy data from DynamoDB in a raw format and write it to HDFS without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in HDFS.

> **Note**
>
> If your DynamoDB table contains attributes of type Map, List, Boolean or Null, then this is the only way you can use Hive to copy data from DynamoDB to HDFS.

Example From DynamoDB to HDFS

1. Create an external table associated with your DynamoDB table. (There is no `dynamodb.column.mapping` in this HiveQL statement.)

```
CREATE EXTERNAL TABLE ddb_features_no_mapping
    (item MAP<STRING, STRING>)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "Features");
```

2. Create another external table associated with your HDFS directory.

```
CREATE EXTERNAL TABLE hdfs_features_no_mapping
    (item MAP<STRING, STRING>)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY '\t'
LINES TERMINATED BY '\n'
LOCATION 'hdfs:///user/hadoop/hive-test';
```

3. Copy the data from DynamoDB to HDFS.

```
INSERT OVERWRITE TABLE hdfs_features_no_mapping
SELECT * FROM ddb_features_no_mapping;
```

The data file in HDFS looks like this:

```
Name^C{"s":"Soldiers Farewell
 Hill"}^BState^C{"s":"NM"}^BClass^C{"s":"Summit"}^BElevation^C{"n":"6135"}^BLatitude^C{"n":"32.
Name^C{"s":"Jones
 Run"}^BState^C{"s":"PA"}^BClass^C{"s":"Stream"}^BElevation^C{"n":"1260"}^BLatitude^C{"n":"41.2
Name^C{"s":"Sentinel
 Dome"}^BState^C{"s":"CA"}^BClass^C{"s":"Summit"}^BElevation^C{"n":"8133"}^BLatitude^C{"n":"37.
Name^C{"s":"Neversweet
 Gulch"}^BState^C{"s":"CA"}^BClass^C{"s":"Valley"}^BElevation^C{"n":"2900"}^BLatitude^C{"n":"41
Name^C{"s":"Chacaloochee
 Bay"}^BState^C{"s":"AL"}^BClass^C{"s":"Bay"}^BElevation^C{"n":"0"}^BLatitude^C{"n":"30.6979676
```

Each field begins with an STX character (start of text, 0x02) and ends with an ETX character (end of text, 0x03). In the file, STX appears as **^B** and ETX appears as **^C**.

Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```
INSERT OVERWRITE TABLE ddb_features_no_mapping
SELECT * FROM hdfs_features_no_mapping;
```

Accessing the data in HDFS

HDFS is a distributed file system, accessible to all of the nodes in the Amazon EMR cluster. If you use SSH to connect to the leader node, you can use command line tools to access the data that Hive wrote to HDFS.

HDFS is not the same thing as the local file system on the leader node. You cannot work with files and directories in HDFS using standard Linux commands (such as `cat`, `cp`, `mv`, or `rm`). Instead, you perform these tasks using the `hadoop fs` command.

The following steps are written with the assumption you have copied data from DynamoDB to HDFS using one of the procedures in this section.

1. If you are currently at the Hive command prompt, exit to the Linux command prompt.

   ```
   hive> exit;
   ```

2. List the contents of the /user/hadoop/hive-test directory in HDFS. (This is where Hive copied the data from DynamoDB.)

   ```
   hadoop fs -ls /user/hadoop/hive-test
   ```

   The response should look similar to this:

   ```
   Found 1 items
   -rw-r--r-- 1 hadoop hadoop 29504 2016-06-08 23:40 /user/hadoop/hive-test/000000_0
   ```

   The file name (*000000_0*) is system-generated.

3. View the contents of the file:

   ```
   hadoop fs -cat /user/hadoop/hive-test/000000_0
   ```

> **Note**
>
> In this example, the file is relatively small (approximately 29 KB). Be careful when you use this command with files that are very large or contain non-printable characters.

4. (Optional) You can copy the data file from HDFS to the local file system on the leader node. After you do this, you can use standard Linux command line utilities to work with the data in the file.

```
hadoop fs -get /user/hadoop/hive-test/000000_0
```

This command will not overwrite the file.

> **Note**
>
> The local file system on the leader node has limited capacity. Do not use this command with files that are larger than the available space in the local file system.

Using data compression

When you use Hive to copy data among different data sources, you can request on-the-fly data compression. Hive provides several compression codecs. You can choose one during your Hive session. When you do this, the data is compressed in the specified format.

The following example compresses data using the Lempel-Ziv-Oberhumer (LZO) algorithm.

```
SET hive.exec.compress.output=true;
SET io.seqfile.compression.type=BLOCK;
SET mapred.output.compression.codec = com.hadoop.compression.lzo.LzopCodec;

CREATE EXTERNAL TABLE lzo_compression_table (line STRING)
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t' LINES TERMINATED BY '\n'
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE lzo_compression_table SELECT *
FROM hiveTableName;
```

The resulting file in Amazon S3 will have a system-generated name with `.lzo` at the end (for example, `8d436957-57ba-4af7-840c-96c2fc7bb6f5-000000.lzo`).

The available compression codecs are:

- `org.apache.hadoop.io.compress.GzipCodec`
- `org.apache.hadoop.io.compress.DefaultCodec`
- `com.hadoop.compression.lzo.LzoCodec`
- `com.hadoop.compression.lzo.LzopCodec`
- `org.apache.hadoop.io.compress.BZip2Codec`
- `org.apache.hadoop.io.compress.SnappyCodec`

Reading non-printable UTF-8 character data

To read and write non-printable UTF-8 character data, you can use the `STORED AS SEQUENCEFILE` clause when you create a Hive table. A SequenceFile is a Hadoop binary file format. You need to use Hadoop to read this file. The following example shows how to export data from DynamoDB into Amazon S3. You can use this functionality to handle non-printable UTF-8 encoded characters.

```
CREATE EXTERNAL TABLE s3_export(a_col string, b_col bigint, c_col array<string>)
STORED AS SEQUENCEFILE
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3_export SELECT *
FROM hiveTableName;
```

Performance tuning

When you create a Hive external table that maps to a DynamoDB table, you do not consume any read or write capacity from DynamoDB. However, read and write activity on the Hive table (such as `INSERT` or `SELECT`) translates directly into read and write operations on the underlying DynamoDB table.

Apache Hive on Amazon EMR implements its own logic for balancing the I/O load on the DynamoDB table and seeks to minimize the possibility of exceeding the table's provisioned throughput. At the end of each Hive query, Amazon EMR returns runtime metrics, including

the number of times your provisioned throughput was exceeded. You can use this information, together with CloudWatch metrics on your DynamoDB table, to improve performance in subsequent requests.

The Amazon EMR console provides basic monitoring tools for your cluster. For more information, see View and Monitor a Cluster in the *Amazon EMR Management Guide*.

You can also monitor your cluster and Hadoop jobs using web-based tools, such as Hue, Ganglia, and the Hadoop web interface. For more information, see View Web Interfaces Hosted on Amazon EMR Clusters in the *Amazon EMR Management Guide*.

This section describes steps you can take to performance-tune Hive operations on external DynamoDB tables.

Topics

- DynamoDB provisioned throughput
- Adjusting the mappers
- Additional topics

DynamoDB provisioned throughput

When you issue HiveQL statements against the external DynamoDB table, the `DynamoDBStorageHandler` class makes the appropriate low-level DynamoDB API requests, which consume provisioned throughput. If there is not enough read or write capacity on the DynamoDB table, the request will be throttled, resulting in slow HiveQL performance. For this reason, you should make sure that the table has enough throughput capacity.

For example, suppose that you have provisioned 100 read capacity units for your DynamoDB table. This will let you read 409,600 bytes per second (100 × 4 KB read capacity unit size). Now suppose that the table contains 20 GB of data (21,474,836,480 bytes) and you want to use the `SELECT` statement to select all of the data using HiveQL. You can estimate how long the query will take to run like this:

21,474,836,480 / 409,600 = 52,429 seconds = 14.56 hours

In this scenario, the DynamoDB table is a bottleneck. It won't help to add more Amazon EMR nodes, because the Hive throughput is constrained to only 409,600 bytes per second. The only way to decrease the time required for the `SELECT` statement is to increase the provisioned read capacity of the DynamoDB table.

You can perform a similar calculation to estimate how long it would take to bulk-load data into a Hive external table mapped to a DynamoDB table. Determine the total number of write capacity units needed per item (less than 1KB = 1, 1-2KB = 2, etc), and multiply that by the number of items to load. This will give you the number of write capacity units required. Divide that number by the number of write capacity units that are allocated per second. This will yield the number of seconds it will take to load the table.

You should regularly monitor the CloudWatch metrics for your table. For a quick overview in the DynamoDB console, choose your table and then choose the **Metrics** tab. From here, you can view read and write capacity units consumed and read and write requests that have been throttled.

Read capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of `ProvisionedThroughputExceeded` messages in the job output, you can adjust the default read rate. To do this, you can modify the `dynamodb.throughput.read.percent` configuration variable. You can use the `SET` command to set this variable at the Hive command prompt:

```
SET dynamodb.throughput.read.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, `dynamodb.throughput.read.percent` will return to its default value.

The value of `dynamodb.throughput.read.percent` can be between `0.1` and `1.5`, inclusively. `0.5` represents the default read rate, meaning that Hive will attempt to consume half of the read capacity of the table. If you increase the value above `0.5`, Hive will increase the request rate; decreasing the value below `0.5` decreases the read request rate. (The actual read rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned read capacity of the table, or if your read requests are being throttled too much, try reducing `dynamodb.throughput.read.percent` below `0.5`. If you have sufficient read capacity in the table and want more responsive HiveQL operations, you can set the value above `0.5`.

Write capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of

`ProvisionedThroughputExceeded` messages in the job output, you can adjust the default write rate. To do this, you can modify the `dynamodb.throughput.write.percent` configuration variable. You can use the `SET` command to set this variable at the Hive command prompt:

```
SET dynamodb.throughput.write.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, `dynamodb.throughput.write.percent` will return to its default value.

The value of `dynamodb.throughput.write.percent` can be between `0.1` and `1.5`, inclusively. `0.5` represents the default write rate, meaning that Hive will attempt to consume half of the write capacity of the table. If you increase the value above `0.5`, Hive will increase the request rate; decreasing the value below `0.5` decreases the write request rate. (The actual write rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned write capacity of the table, or if your write requests are being throttled too much, try reducing `dynamodb.throughput.write.percent` below `0.5`. If you have sufficient capacity in the table and want more responsive HiveQL operations, you can set the value above `0.5`.

When you write data to DynamoDB using Hive, make sure that the number of write capacity units is greater than the number of mappers in the cluster. For example, consider an Amazon EMR cluster consisting of 10 *m1.xlarge* nodes. The *m1.xlarge* node type provides 8 mapper tasks, so the cluster would have a total of 80 mappers (10 × 8). If your DynamoDB table has fewer than 80 write capacity units, then a Hive write operation could consume all of the write throughput for that table.

To determine the number of mappers for Amazon EMR node types, see Task Configuration in the *Amazon EMR Developer Guide*.

For more information on mappers, see Adjusting the mappers.

Adjusting the mappers

When Hive launches a Hadoop job, the job is processed by one or more mapper tasks. Assuming that your DynamoDB table has sufficient throughput capacity, you can modify the number of mappers in the cluster, potentially improving performance.

> **Note**
>
> The number of mapper tasks used in a Hadoop job are influenced by *input splits*, where Hadoop subdivides the data into logical blocks. If Hadoop does not perform enough input splits, then your write operations might not be able to consume all the write throughput available in the DynamoDB table.

Increasing the number of mappers

Each mapper in an Amazon EMR has a maximum read rate of 1 MiB per second. The number of mappers in a cluster depends on the size of the nodes in your cluster. (For information about node sizes and the number of mappers per node, see Task Configuration in the *Amazon EMR Developer Guide*.)

If your DynamoDB table has ample throughput capacity for reads, you can try increasing the number of mappers by doing one of the following:

- Increase the size of the nodes in your cluster. For example, if your cluster is using *m1.large* nodes (three mappers per node), you can try upgrading to *m1.xlarge* nodes (eight mappers per node).
- Increase the number of nodes in your cluster. For example, if you have three-node cluster of *m1.xlarge* nodes, you have a total of 24 mappers available. If you were to double the size of the cluster, with the same type of node, you would have 48 mappers.

You can use the AWS Management Console to manage the size or the number of nodes in your cluster. (You might need to restart the cluster for these changes to take effect.)

Another way to increase the number of mappers is to modify the `mapred.tasktracker.map.tasks.maximum` Hadoop configuration parameter. (This is a Hadoop parameter, not a Hive parameter. You cannot modify it interactively from the command prompt.). If you increase the value of `mapred.tasktracker.map.tasks.maximum`, you can increase the number of mappers without increasing the size or number of nodes. However, it is possible for the cluster nodes to run out of memory if you set the value too high.

You set the value for `mapred.tasktracker.map.tasks.maximum` as a bootstrap action when you first launch your Amazon EMR cluster. For more information, see (Optional) Create Bootstrap Actions to Install Additional Software in the *Amazon EMR Management Guide*.

Decreasing the number of mappers

If you use the SELECT statement to select data from an external Hive table that maps to DynamoDB, the Hadoop job can use as many tasks as necessary, up to the maximum number of mappers in the cluster. In this scenario, it is possible that a long-running Hive query can consume all of the provisioned read capacity of the DynamoDB table, negatively impacting other users.

You can use the `dynamodb.max.map.tasks` parameter to set an upper limit for map tasks:

```
SET dynamodb.max.map.tasks=1
```

This value must be equal to or greater than 1. When Hive processes your query, the resulting Hadoop job will use no more than `dynamodb.max.map.tasks` when reading from the DynamoDB table.

Additional topics

The following are some more ways to tune applications that use Hive to access DynamoDB.

Retry duration

By default, Hive will rerun a Hadoop job if it has not returned any results from DynamoDB within two minutes. You can adjust this interval by modifying the `dynamodb.retry.duration` parameter:

```
SET dynamodb.retry.duration=2;
```

The value must be a nonzero integer, representing the number of minutes in the retry interval. The default for `dynamodb.retry.duration` is 2 (minutes).

Parallel data requests

Multiple data requests, either from more than one user or more than one application to a single table can drain read provisioned throughput and slow performance.

Process duration

Data consistency in DynamoDB depends on the order of read and write operations on each node. While a Hive query is in progress, another application might load new data into the DynamoDB

table or modify or delete existing data. In this case, the results of the Hive query might not reflect changes made to the data while the query was running.

Request time

Scheduling Hive queries that access a DynamoDB table when there is lower demand on the DynamoDB table improves performance. For example, if most of your application's users live in San Francisco, you might choose to export daily data at 4:00 A.M. PST when the majority of users are asleep and not updating records in your DynamoDB database.

Integrating DynamoDB with Amazon S3

Amazon DynamoDB import and export capabilities provide a simple and efficient way to move data between Amazon S3 and DynamoDB tables without writing any code.

DynamoDB import and export features help you move, transform, and copy DynamoDB table accounts. You can import from your S3 sources, and you can export your DynamoDB table data to Amazon S3 and use AWS services such as Athena, Amazon SageMaker AI, and AWS Lake Formation to analyze your data and extract actionable insights. You can also import data directly into new DynamoDB tables to build new applications with single-digit millisecond performance at scale, facilitate data sharing between tables and accounts, and simplify your disaster recovery and business continuity plans.

- DynamoDB data export to Amazon S3: how it works

DynamoDB data import from Amazon S3: how it works

To import data into DynamoDB, your data must be in an Amazon S3 bucket in CSV, DynamoDB JSON, or Amazon Ion format. Data can be compressed in ZSTD or GZIP format, or can be directly imported in uncompressed form. Source data can either be a single Amazon S3 object or multiple Amazon S3 objects that use the same prefix.

Your data will be imported into a new DynamoDB table, which will be created when you initiate the import request. You can create this table with global secondary indexes (local secondary

indexes are not supported), then query and update your data across all primary and secondary indexes as soon as the import is complete. You can also add a global table replica after the import is complete.

> **Note**
>
> During the Amazon S3 import process, DynamoDB creates a new target table that will be imported into. Import into existing tables is not currently supported by this feature.

Import from Amazon S3 does not consume write capacity on the new table, so you do not need to provision any extra capacity for importing data into DynamoDB. Data import pricing is based on the uncompressed size of the source data in Amazon S3, that is processed as a result of the import. Items that are processed but fail to load into the table due to formatting or other inconsistencies in the source data are also billed as part of the import process. See Amazon DynamoDB pricing for details.

You can import data from an Amazon S3 bucket owned by a different account if you have the correct permissions to read from that specific bucket. The new table might also be in a different Region from the source Amazon S3 bucket. For more information, see Amazon Simple Storage Service setup and permissions .

Import times are directly related to your data's characteristics in Amazon S3. This includes data size, data format, compression scheme, uniformity of data distribution, number of Amazon S3 objects, and other related variables. In particular, data sets with uniformly distributed keys will be faster to import than skewed data sets. For example, if your secondary index's key is using the month of the year for partitioning, and all your data is from the month of December, then importing this data might take significantly longer.

The attributes associated with keys are expected to be unique on the base table. If any keys are not unique, the import will overwrite the associated items until only the last overwrite remains. For example, if the primary key is the month and multiple items are set to the month of September, each new item will overwrite the previously written items and only one item with the primary key of "month" set to September will remain. In such cases, the number of items processed in the import table description will not match the number of items in the target table.

AWS CloudTrail logs all console and API actions for table import. For more information, see Logging DynamoDB operations by using AWS CloudTrail.

The following video is an introduction to importing directly from Amazon S3 into DynamoDB.

Import from Amazon S3

- Best practices for importing from Amazon S3 into DynamoDB

Requesting a table import in DynamoDB

DynamoDB import allows you to import data from an Amazon S3 bucket to a new DynamoDB table. You can request a table import using the DynamoDB console, the CLI, CloudFormation or the DynamoDB API.

If you want to use the AWS CLI, you must configure it first. For more information, see Accessing DynamoDB.

> **Note**
>
> - The Import Table feature interacts with multiple different AWS Services such as Amazon S3 and CloudWatch. Before you begin an import, make sure that the user or role that invokes the import APIs has permissions to all services and resources the feature depends on.
> - Do not modify the Amazon S3 objects while the import is in progress, as this can cause the operation to fail or be cancelled.
>
> For more information on errors and troubleshooting, see Import format quotas and validation

Topics

- Setting up IAM permissions
- Requesting an import using the AWS Management Console
- Getting details about past imports in the AWS Management Console

- Requesting an import using the AWS CLI
- Getting details about past imports in the AWS CLI

Setting up IAM permissions

You can import data from any Amazon S3 bucket you have permission to read from. The source bucket does not need to be in the same Region or have the same owner as the source table. Your AWS Identity and Access Management (IAM) must include the relevant actions on the source Amazon S3 bucket, and required CloudWatch permissions for providing debugging information. An example policy is shown below.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDynamoDBImportAction",
      "Effect": "Allow",
      "Action": [
        "dynamodb:ImportTable",
        "dynamodb:DescribeImport"
      ],
      "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/my-table*"
    },
    {
      "Sid": "AllowS3Access",
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::your-bucket/*",
        "arn:aws:s3:::your-bucket"
      ]
    },
    {
      "Sid": "AllowCloudwatchAccess",
      "Effect": "Allow",
      "Action": [
```

```
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:PutLogEvents",
        "logs:PutRetentionPolicy"
      ],
      "Resource": "arn:aws:logs:us-east-1:111122223333:log-group/aws-dynamodb/*"
    },
    {
      "Sid": "AllowDescribeLogGroups",
      "Effect": "Allow",
      "Action": "logs:DescribeLogGroups",
      "Resource": "*"
    },
    {
      "Sid": "AllowDynamoDBListImports",
      "Effect": "Allow",
      "Action": "dynamodb:ListImports",
      "Resource": "*"
    }
  ]
}
```

Amazon S3 permissions

When starting an import on an Amazon S3 bucket source that is owned by another account, make sure that the role or user has access to the Amazon S3 objects. You can check that by executing an Amazon S3 `GetObject` command and using the credentials. When using the API, the Amazon S3 bucket owner parameter defaults to the current user's account ID. For cross account imports, make sure that this parameter is correctly populated with the bucket owner's account ID. The following code is an example Amazon S3 bucket policy in the source account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {"Sid": "ExampleStatement",
            "Effect": "Allow",
            "Principal": {"AWS": "arn:aws:iam::123456789012:user/Dave"
            },
```

```
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

AWS Key Management Service

When creating the new table for import, if you select an encryption at rest key that is not owned by DynamoDB then you must provide the AWS KMS permissions required to operate a DynamoDB table encrypted with customer managed keys. For more information see Authorizing use of your AWS KMS key. If the Amazon S3 objects are encrypted with server side encryption KMS (SSE-KMS), make sure that the role or user initiating the import has access to decrypt using the AWS KMS key. This feature does not support customer-provided encryption keys (SSE-C) encrypted Amazon S3 objects.

CloudWatch permissions

The role or user that is initiating the import will need create and manage permissions for the log group and log streams associated with the import.

Requesting an import using the AWS Management Console

The following example demonstrates how to use the DynamoDB console to import existing data to a new table named `MusicCollection`.

To request a table import

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Import from S3**.
3. On the page that appears, select **Import from S3**.
4. Choose **Import from S3**.
5. In **Source S3 URL**, enter the Amazon S3 source URL.

   If you own the source bucket, choose **Browse S3** to search for it. Alternatively, enter the bucket's URL in the following format – `s3://bucket/prefix`. The `prefix` is an Amazon S3

key prefix. It's either the Amazon S3 object name that you want to import or the key prefix shared by all the Amazon S3 objects that you want to import.

> **Note**
>
> You can't use the same prefix as your DynamoDB export request. The export feature creates a folder structure and manifest files for all the exports. If you use the same Amazon S3 path, it will result in an error.
> Instead, point the import at the folder, which contains data from that specific export. The format of the correct path in this case will be `s3://bucket/prefix/AWSDynamoDB/<XXXXXXXX-XXXXXX>/data/`, where `XXXXXXXX-XXXXXX` is the export ID. You can find export ID in the export ARN, which has the following format – `arn:aws:dynamodb:<Region>:<AccountID>:table/<TableName>/export/<XXXXXXXX-XXXXXX>`. For example, `arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/export/01234567890123-a1b2c3d4`.

6. Specify if you are the **S3 bucket owner**. If the source bucket is owned by a different account, select **A different AWS account**. Then enter the account ID of the bucket owner.
7. Under **Import file compression**, select either **No compression**, **GZIP** or **ZSTD** as appropriate.
8. Select the appropriate Import file format. The options are **DynamoDB JSON**, **Amazon Ion** or **CSV**. If you select **CSV**, you will have two additional options: **CSV header** and **CSV delimiter character**.

   For **CSV header**, choose if the header will either be taken from the first line of the file or be customized. If you select **Customize your headers**, you can specify the header values you want to import with. CSV Headers specified by this method are case-sensitive and are expected to contain the keys of the target table.

   For **CSV delimiter character**, you set the character which will separate items. Comma is selected by default. If you select **Custom delimiter character**, the delimiter must match the regex pattern: `[,;:|\t ]`.
9. Select the **Next** button and select the options for the new table that will be created to store your data.

> **Note**
>
> Primary Key and Sort Key must match the attributes in the file, or the import will fail. The attributes are case sensitive.

10. Select **Next** again to review your import options, then choose **Import** to begin the import task. You will first see your new table listed in the “Tables” with the status “Creating”. At this time the table is not accessible.
11. After the import completes, the status shows as "Active" and you can start using the table.

Getting details about past imports in the AWS Management Console

You can find information about import tasks you've run in the past by clicking **Import from S3** in the navigation sidebar, then selecting the **Imports** tab. The import panel contains a list of all imports you've created in the past 90 days. Selecting the ARN of a task listed in the Imports tab will retrieve information about that import, including any advanced configuration settings you chose.

Requesting an import using the AWS CLI

The following example imports CSV formatted data from an S3 bucket called bucket with a prefix of prefix to a new table called target-table.

```
aws dynamodb import-table --s3-bucket-source S3Bucket=bucket,S3KeyPrefix=prefix \
            --input-format CSV --table-creation-parameters '{"TableName":"target-
table","KeySchema":  \
            [{"AttributeName":"hk","KeyType":"HASH"}],"AttributeDefinitions":
[{"AttributeName":"hk","AttributeType":"S"}],"BillingMode":"PAY_PER_REQUEST"}' \
            --input-format-options '{"Csv": {"HeaderList": ["hk", "title", "artist",
 "year_of_release"], "Delimiter": ";"}}'
```

> **Note**
>
> If you choose to encrypt your import using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination Amazon S3 bucket.

Getting details about past imports in the AWS CLI

You can find information about import tasks you've run in the past by using the `list-imports` command. This command returns a list of all imports you've created in the past 90 days. Note that although import task metadata expires after 90 days and jobs older than that are no longer found on this list, DynamoDB does not delete any of the objects in your Amazon S3 bucket or the table created during import.

```
aws dynamodb list-imports
```

To retrieve detailed information about a specific import task, including any advanced configuration settings, use the `describe-import` command.

```
aws dynamodb describe-import \
    --import-arn arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/exp
```

Amazon S3 import formats for DynamoDB

DynamoDB can import data in three formats: CSV, DynamoDB JSON, and Amazon Ion.

Topics

- CSV
- DynamoDB Json
- Amazon Ion

CSV

A file in CSV format consists of multiple items delimited by newlines. By default, DynamoDB interprets the first line of an import file as the header and expects columns to be delimited by commas. You can also define headers that will be applied, as long as they match the number of columns in the file. If you define headers explicitly, the first line of the file will be imported as values.

> **Note**
>
> When importing from CSV files, all columns other than the hash range and keys of your base table and secondary indexes are imported as DynamoDB strings.

Escaping double quotes

Any double quotes characters that exist in the CSV file must be escaped. If they are not escaped, such as in this following example, the import will fail:

```
id,value
"123",Women's Full "Length" Dress
```

This same import will succeed if the quotes are escaped with two sets of double quotes:

```
id,value
"""123""","Women's Full ""Length"" Dress"
```

Once the text has been properly escaped and imported, it will appear as it did in the original CSV file:

```
id,value
"123",Women's Full "Length" Dress
```

DynamoDB follows the standard CSV quoting convention (RFC 4180): a double quote inside a field value is escaped by preceding it with another double quote (""). Backslash escaping (\"), which is common in programming languages and in the output of many data-export tools, is *not* recognized, and a file that uses it will fail to import. If your source data uses backslash escaping, convert each escaped quote to a doubled quote before importing. For example, a value exported as:

```
"Women's \"Full Length\" Dress"
```

must be reformatted as follows before it can be imported:

```
"Women's ""Full Length"" Dress"
```

Formatting key values

In DynamoDB, a primary key is either a *simple* primary key (a partition key) or a *composite* primary key (a partition key and a sort key). Each key attribute holds a single scalar value. If you want a key value that combines several fields — for example, joining `organizationId` and `barcode` with a delimiter as `organizationId#barcode` — you concatenate those fields into one string and store

it in a single key attribute. This concatenation is an application convention; DynamoDB stores and matches the key attribute as one value.

When you import this data from CSV, put the fully joined value in a single column whose header matches the name of the key attribute. Do not split the parts into separate columns: the import maps each column to one attribute and does not concatenate columns into a key value. For example, for a table whose partition key attribute is named `pk` and sort key attribute is named `sk`:

```
pk,sk,barcode
org123#ABC123,number#001,ABC123
org456#XYZ789,number#002,XYZ789
```

If a key value itself contains the comma delimiter, enclose the entire value in double quotes, for example `"org123,east#ABC123"`.

Importing heterogeneous item types

You can use a single CSV file to import different item types into one table. Define a header row that includes all attributes across your item types, and leave columns empty for attributes that don't apply to a given item. Empty columns are omitted from the imported item rather than stored as empty strings.

```
PK,SK,EntityType,Name,Email,OrderDate,Amount,ProductName,Quantity
USER#1,PROFILE,User,Alice,alice@example.com,,,,
USER#1,ORDER#2024-01-15,Order,,,2024-01-15,99.99,,
USER#1,ORDER#2024-02-10,Order,,,2024-02-10,149.50,,
PRODUCT#101,METADATA,Product,,,,,Laptop,50
PRODUCT#102,METADATA,Product,,,,,Mouse,200
USER#2,PROFILE,User,Bob,bob@example.com,,,,
USER#2,ORDER#2024-01-20,Order,,,2024-01-20,75.00,,
PRODUCT#103,METADATA,Product,,,,,Keyboard,150
USER#3,PROFILE,User,Charlie,charlie@example.com,,,,
PRODUCT#104,METADATA,Product,,,,,Monitor,30
```

In this example, user profiles, orders, and products share the same table. Each item type uses only the columns relevant to it.

DynamoDB Json

A file in DynamoDB JSON format can consist of multiple Item objects. Each individual object is in DynamoDB's standard marshalled JSON format, and newlines are used as item delimiters. This is

the JSON Lines (JSONL) format: one JSON object per line, with no enclosing array and no commas between items. As an added feature, exports from point in time are supported as an import source by default.

> **Note**
>
> New lines are used as item delimiters for a file in DynamoDB JSON format and shouldn't be used within an item object.

```
{"Item": {"Authors": {"SS": ["Author1", "Author2"]}, "Dimensions": {"S": "8.5 x 11.0 x
 1.5"}, "ISBN": {"S": "333-3333333333"}, "Id": {"N": "103"}, "InPublication": {"BOOL":
 false}, "PageCount": {"N": "600"}, "Price": {"N": "2000"}, "ProductCategory": {"S":
 "Book"}, "Title": {"S": "Book 103 Title"}}}
{"Item": {"Authors": {"SS": ["Author1", "Author2"]}, "Dimensions": {"S": "8.5 x 11.0 x
 1.5"}, "ISBN": {"S": "444-444444444"}, "Id": {"N": "104"}, "InPublication": {"BOOL":
 false}, "PageCount": {"N": "600"}, "Price": {"N": "2000"}, "ProductCategory": {"S":
 "Book"}, "Title": {"S": "Book 104 Title"}}}
{"Item": {"Authors": {"SS": ["Author1", "Author2"]}, "Dimensions": {"S": "8.5 x 11.0 x
 1.5"}, "ISBN": {"S": "555-5555555555"}, "Id": {"N": "105"}, "InPublication": {"BOOL":
 false}, "PageCount": {"N": "600"}, "Price": {"N": "2000"}, "ProductCategory": {"S":
 "Book"}, "Title": {"S": "Book 105 Title"}}}
```

Amazon Ion

Amazon Ion is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures.

When you import data in Ion format, the Ion datatypes are mapped to DynamoDB datatypes in the new DynamoDB table.

S. No.	Ion to DynamoDB datatype conversion	B
1	`Ion Data Type`	`DynamoDB Representation`
2	`string`	`String (s)`

S. No.	Ion to DynamoDB datatype conversion	B
3	bool	Boolean (BOOL)
4	decimal	Number (N)
5	blob	Binary (B)
6	list (with type annotation $dynamodb_SS, $dynamodb_NS, or $dynamodb_BS)	Set (SS, NS, BS)
7	list	List
8	struct	Map

Items in an Ion file are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format.

> **Note**
>
> In the following example, we've formatted items from an Ion-formatted file on multiple lines to improve readability.

```
$ion_1_0
[
  {
    Item:{
      Authors:$dynamodb_SS::["Author1","Author2"],
      Dimensions:"8.5 x 11.0 x 1.5",
      ISBN:"333-3333333333",
      Id:103.,
      InPublication:false,
      PageCount:6d2,
      Price:2d3,
      ProductCategory:"Book",
```

```
      Title:"Book 103 Title"
    }
  },
  {
    Item:{
      Authors:$dynamodb_SS::["Author1","Author2"],
      Dimensions:"8.5 x 11.0 x 1.5",
      ISBN:"444-4444444444",
      Id:104.,
      InPublication:false,
      PageCount:6d2,
      Price:2d3,
      ProductCategory:"Book",
      Title:"Book 104 Title"
    }
  },
  {
    Item:{
      Authors:$dynamodb_SS::["Author1","Author2"],
      Dimensions:"8.5 x 11.0 x 1.5",
      ISBN:"555-5555555555",
      Id:105.,
      InPublication:false,
      PageCount:6d2,
      Price:2d3,
      ProductCategory:"Book",
      Title:"Book 105 Title"
    }
  }
]
```

Import format quotas and validation

Import quotas

DynamoDB Import from Amazon S3 can support up to 50 concurrent import jobs with a total import source object size of 15TB at a time in us-east-1, us-west-2, and eu-west-1 regions. In all other regions, up to 50 concurrent import tasks with a total size of 1TB is supported. Each import job can take up to 50,000 Amazon S3 objects in all regions. These default quotas are applied to every account. If you feel you need to revise these quotas, please contact your account team, and this will be considered on a case-by-case basis. For more details on DynamoDB limits, see Service Quotas.

Validation errors

During the import process, DynamoDB may encounter errors while parsing your data. For each error, DynamoDB emits a CloudWatch log and keeps a count of the total number of errors encountered. If the Amazon S3 object itself is malformed or if its contents cannot form a DynamoDB item, then we may skip processing the remaining portion of the object.

> **Note**
>
> If the Amazon S3 data source has multiple items that share the same key, the items will overwrite until one remains. This can appear as if 1 item was imported and the others were ignored. The duplicate items will be overwritten in random order, are not counted as errors, and are not emitted to CloudWatch logs.
> Once the import is complete you can see the total count of items imported, total count of errors, and total count of items processed. For further troubleshooting you can also check the total size of items imported and total size of data processed.

There are three categories of import errors: API validation errors, data validation errors, and configuration errors.

API validation errors

API validation errors are item-level errors from the sync API. Common causes are permissions issues, missing required parameters and parameter validation failures. Details on why the API call failed are contained in the exceptions thrown by the `ImportTable` request.

Data validation errors

Data validation errors can occur at either the item level or file level. During import, items are validated based on DynamoDB rules before importing into the target table. When an item fails validation and is not imported, the import job skips over that item and continues on with the next item. At the end of job, the import status is set to FAILED with a FailureCode, ItemValidationError and the FailureMessage "Some of the items failed validation checks and were not imported. Please check CloudWatch error logs for more details."

Common causes for data validation errors include objects being unparsable, objects being in the incorrect format (input specifies DYNAMODB_JSON but the object is not in DYNAMODB_JSON), and schema mismatch with specified source table keys.

Configuration errors

Configuration errors are typically workflow errors due to permission validation. The Import workflow checks some permissions after accepting the request. If there are issues calling any of the required dependencies like Amazon S3 or CloudWatch the process marks the import status as FAILED. The `failureCode` and `failureMessage` point to the reason for failure. Where applicable, the failure message also contains the request id that you can use to investigate the reason for failure in CloudTrail.

Common configuration errors include having the wrong URL for the Amazon S3 bucket, and not having permission to access the Amazon S3 bucket, CloudWatch Logs, and AWS KMS keys used to decrypt the Amazon S3 object. For more information see Using and data keys.

Validating source Amazon S3 objects

In order to validate source S3 objects, take the following steps.

1. Validate the data format and compression type

   - Make sure that all matching Amazon S3 objects under the specified prefix have the same format (DYNAMODB_JSON, DYNAMODB_ION, CSV)
   - Make sure that all matching Amazon S3 objects under the specified prefix are compressed the same way (GZIP, ZSTD, NONE)

   > **Note**
   >
   > The Amazon S3 objects do not need to have the corresponding extension (.csv / .json / .ion / .gz / .zstd etc) as the input format specified in ImportTable call takes precedence.

2. Validate that the import data conforms to the desired table schema

   - Make sure that each item in the source data has the primary key. A sort key is optional for imports.
   - Make sure that the attribute type associated with the primary key and any sort key matches the attribute type in the Table and the GSI schema, as specified in table creation parameters

Troubleshooting

CloudWatch logs

For Import jobs that fail, detailed error messages are posted to CloudWatch logs. To access these logs, first retrieve the ImportArn from the output and describe-import using this command:

```
aws dynamodb describe-import --import-arn arn:aws:dynamodb:us-east-1:ACCOUNT:table/
target-table/import/01658528578619-c4d4e311
```

Example output:

```
aws dynamodb describe-import --import-arn "arn:aws:dynamodb:us-
east-1:531234567890:table/target-table/import/01658528578619-c4d4e311"
{
    "ImportTableDescription": {
        "ImportArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table/
import/01658528578619-c4d4e311",
        "ImportStatus": "FAILED",
        "TableArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table",
        "TableId": "7b7ecc22-302f-4039-8ea9-8e7c3eb2bcb8",
        "ClientToken": "30f8891c-e478-47f4-af4a-67a5c3b595e3",
        "S3BucketSource": {
            "S3BucketOwner": "ACCOUNT",
            "S3Bucket": "my-import-source",
            "S3KeyPrefix": "import-test"
        },
        "ErrorCount": 1,
        "CloudWatchLogGroupArn": "arn:aws:logs:us-east-1:ACCOUNT:log-group:/aws-
dynamodb/imports:*",
        "InputFormat": "CSV",
        "InputCompressionType": "NONE",
        "TableCreationParameters": {
            "TableName": "target-table",
            "AttributeDefinitions": [
                {
                    "AttributeName": "pk",
                    "AttributeType": "S"
                }
            ],
            "KeySchema": [
                {
                    "AttributeName": "pk",
```

```
                    "KeyType": "HASH"
                }
            ],
            "BillingMode": "PAY_PER_REQUEST"
        },
        "StartTime": 1658528578.619,
        "EndTime": 1658528750.628,
        "ProcessedSizeBytes": 70,
        "ProcessedItemCount": 1,
        "ImportedItemCount": 0,
        "FailureCode": "ItemValidationError",
        "FailureMessage": "Some of the items failed validation checks and were not
 imported. Please check CloudWatch error logs for more details."
    }
}
```

Retrieve the log group and the import id from the above response and use it to retrieve the error logs. The import ID is the last path element of the `ImportArn` field. The log group name is `/aws-dynamodb/imports`. The error log stream name is `import-id/error`. For this example, it would be `01658528578619-c4d4e311/error`.

Missing the key pk in the item

If the source S3 object does not contain the primary key that was provided as a parameter, the import will fail. For example, when you define the primary key for the import as column name “pk”.

```
aws dynamodb import-table –s3-bucket-source S3Bucket=my-import-
source,S3KeyPrefix=import-test.csv \
            –input-format CSV --table-creation-parameters '{"TableName":"target-
table","KeySchema":  \
            [{"AttributeName":"pk","KeyType":"HASH"}],"AttributeDefinitions":
[{"AttributeName":"pk","AttributeType":"S"}],"BillingMode":"PAY_PER_REQUEST"}'
```

The column “pk” is missing from the the source object `import-test.csv` which has the following contents:

```
title,artist,year_of_release
The Dark Side of the Moon,Pink Floyd,1973
```

This import will fail due to item validation error because of the missing primary key in the data source.

Example CloudWatch error log:

```
aws logs get-log-events –log-group-name /aws-dynamodb/imports –log-stream-name
 01658528578619-c4d4e311/error
{
    "events": [
        {
            "timestamp": 1658528745319,
            "message": "{\"itemS3Pointer\":{\"bucket\":\"my-import-source\",
\"key\":\"import-test.csv\",\"itemIndex\":0},\"importArn\":\"arn:aws:dynamodb:us-
east-1:531234567890:table/target-table/import/01658528578619-c4d4e311\",\"errorMessages
\":[\"One or more parameter values were invalid: Missing the key pk in the item\"]}",
            "ingestionTime": 1658528745414
        }
    ],
    "nextForwardToken": "f/36986426953797707963335499204463414460239026137054642176/s",
    "nextBackwardToken": "b/36986426953797707963335499204463414460239026137054642176/s"
}
```

This error log indicates that “One or more parameter values were invalid: Missing the key pk in the item”. Since this import job failed, the table “target-table” now exists and is empty because no items were imported. The first item was processed and the object failed Item Validation.

To fix the issue, first delete “target-table” if it is no longer needed. Then either use a primary key column name that exists in the source object, or update the source data to:

```
pk,title,artist,year_of_release
Albums::Rock::Classic::1973::AlbumId::ALB25,The Dark Side of the Moon,Pink Floyd,1973
```

Target table exists

When you start an import job and receive a response as follows:

```
An error occurred (ResourceInUseException) when calling the ImportTable operation:
 Table already exists: target-table
```

To fix this error, you will need to choose a table name that doesn’t already exist and retry the import.

The specified bucket does not exist

If the source bucket does not exist, the import will fail and log the error message details in CloudWatch.

Example describe import:

```
aws dynamodb –endpoint-url $ENDPOINT describe-import –import-arn "arn:aws:dynamodb:us-
east-1:531234567890:table/target-table/import/01658530687105-e6035287"
{
    "ImportTableDescription": {
        "ImportArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table/
import/01658530687105-e6035287",
        "ImportStatus": "FAILED",
        "TableArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table",
        "TableId": "e1215a82-b8d1-45a8-b2e2-14b9dd8eb99c",
        "ClientToken": "3048e16a-069b-47a6-9dfb-9c259fd2fb6f",
        "S3BucketSource": {
            "S3BucketOwner": "531234567890",
            "S3Bucket": "BUCKET_DOES_NOT_EXIST",
            "S3KeyPrefix": "import-test"
        },
        "ErrorCount": 0,
        "CloudWatchLogGroupArn": "arn:aws:logs:us-east-1:ACCOUNT:log-group:/aws-
dynamodb/imports:*",
        "InputFormat": "CSV",
        "InputCompressionType": "NONE",
        "TableCreationParameters": {
            "TableName": "target-table",
            "AttributeDefinitions": [
                {
                    "AttributeName": "pk",
                    "AttributeType": "S"
                }
            ],
            "KeySchema": [
                {
                    "AttributeName": "pk",
                    "KeyType": "HASH"
                }
            ],
            "BillingMode": "PAY_PER_REQUEST"
        },
        "StartTime": 1658530687.105,
```

```
        "EndTime": 1658530701.873,
        "ProcessedSizeBytes": 0,
        "ProcessedItemCount": 0,
        "ImportedItemCount": 0,
        "FailureCode": "S3NoSuchBucket",
        "FailureMessage": "The specified bucket does not exist (Service: Amazon
 S3; Status Code: 404; Error Code: NoSuchBucket; Request ID: Q4W6QYYFDWY6WAKH;
 S3 Extended Request ID: ObqSlLeIMJpQqHLRX2C5Sy7n+8g6iGPwy7ixg7eEeTuEkg/+chU/JF
+RbliWytMlkUlUcuCLTrI=; Proxy: null)"
    }
}
```

The `FailureCode` is `S3NoSuchBucket`, with `FailureMessage` containing details such as request id and the service that threw the error. Since the error was caught before the data was imported into the table, a new DynamoDB table is not created. In some cases, when these errors are encountered after the data import has started, the table with partially imported data is retained.

To fix this error, make sure that the source Amazon S3 bucket exists and then restart the import process.

Best practices for importing from Amazon S3 into DynamoDB

The following are the best practices for importing data from Amazon S3 into DynamoDB.

Stay under the limit of 50,000 S3 objects

Each import job supports a maximum of 50,000 S3 objects. If your dataset contains more than 50,000 objects, consider consolidating them into larger objects.

Avoid excessively large S3 objects

S3 objects are imported in parallel. Having numerous mid-sized S3 objects allows for parallel execution without excessive overhead. For items under 1 KB, consider placing 4,000,000 items into each S3 object. If you have a larger average item size, place proportionally fewer items into each S3 object.

Randomize sorted data

If an S3 object holds data in sorted order, it can create a *rolling hot partition*. This is a situation where one partition receives all the activity, and then the next partition after that, and so on. Data in sorted order is defined as items in sequence in the S3 object that will be written to the same

target partition during the import. One common situation where data is in sorted order is a CSV file where items are sorted by partition key so that repeated items share the same partition key.

To avoid a rolling hot partition, we recommend that you randomize the order in these cases. This can improve performance by spreading the write operations. For more information, see Distributing write activity efficiently during data upload in DynamoDB.

Compress data to keep the total S3 object size below the Regional limit

In the import from S3 process, there is a limit on the sum total size of the S3 object data to be imported. The limit is 15 TB in the us-east-1, us-west-2, and eu-west-1 Regions, and 1 TB in all other Regions. The limit is based on the raw S3 object sizes.

Compression allows more raw data to fit within the limit. If compression alone isn't sufficient to fit the import within the limit, you can also contact AWS Premium Support for a quota increase.

Be aware of how item size impacts performance

If your average item size is very small (below 200 bytes), the import process might take a little longer than for larger item sizes.

Do not modify S3 objects during active imports

Make sure that your source S3 objects remain unchanged while an import operation is in progress. If an S3 object is modified during an import, the operation will fail with error code `ObjectModifiedInS3DuringImport` and the message "The S3 object could not be imported because it was overwritten."

If you encounter this error, restart the import operation with a stable version of your S3 object. To avoid this issue, wait for the current import to complete before making changes to the source files.

Consider importing without any Global Secondary Indexes

The duration of an import task might depend on the presence of one or multiple global secondary indexes (GSIs). If you plan to establish indexes with partition keys that have low cardinality, you might see a faster import if you defer index creation until after the import task is finished (rather than including them in the import job).

> **Note**
>
> Creating a GSI does not incur write charges, whether it is created during or after the import.

DynamoDB data export to Amazon S3: how it works

DynamoDB export to S3 is a fully managed solution for exporting your DynamoDB data to an Amazon S3 bucket at scale. Using DynamoDB export to S3, you can export data from an Amazon DynamoDB table from any time within your point-in-time recovery (PITR) window to an Amazon S3 bucket. You need to enable PITR on your table to use the export functionality. This feature enables you to perform analytics and complex queries on your data using other AWS services such as Athena, AWS Glue, Amazon SageMaker AI, Amazon EMR, and AWS Lake Formation.

DynamoDB export to S3 allows you to export both full and incremental data from your DynamoDB table. You can also run a filtered export with both full exports and incremental exports to get only a subset of your table data instead of the entire table. For more information, see Filtering a table export. Exports are asynchronous, they don't consume read capacity units (RCUs) and have no impact on table performance and availability. The export file formats supported are DynamoDB JSON and Amazon Ion formats. You can also export data to an S3 bucket owned by another AWS account and to a different AWS region. Your data is always encrypted end-to-end.

> **Note**
>
> No service-level agreement (SLA) guarantees export completion times, and these times can vary. An export's duration depends on factors such as the size of the table or data being exported, how the data is distributed across the table, and other exports that are in progress. For this reason, avoid building workflows that depend on an export completing within a fixed amount of time.

DynamoDB full exports are charged based on the size of the DynamoDB table (table data and local secondary indexes) at the point in time for which the export is done. DynamoDB incremental exports are charged based on the size of data processed from your continuous backups for the time period being exported. Incremental export has a minimum charge of 10MB. A filtered export is charged at the same rate, with no additional charge for filtering. When a filtered export uses a key condition to select a single partition key value, the export reads less data, and you are charged only for that matched data, subject to a 10 MB minimum per export. Additional charges apply for storing exported data in Amazon S3 and for PUT requests made against your Amazon S3 bucket. For more information about these charges, see Amazon DynamoDB pricing and Amazon S3 pricing.

For specifics on service quotas, see Table export to Amazon S3.

- DynamoDB table export output format

Requesting a table export in DynamoDB

DynamoDB table exports allow you to export table data to an Amazon S3 bucket, enabling you to perform analytics and complex queries on your data using other AWS services such as Athena, AWS Glue, Amazon SageMaker AI, Amazon EMR, and AWS Lake Formation. You can request a table export using the AWS Management Console, the AWS CLI, or the DynamoDB API.

> **Note**
>
> Requester pays Amazon S3 buckets aren't supported.

DynamoDB supports both full export and incremental export:

- With **full exports**, you can export a full snapshot of your table from any point in time within the point-in-time recovery (PITR) window to your Amazon S3 bucket.
- With **incremental exports**, you can export data from your DynamoDB table that was changed, updated, or deleted between a specified time period, within your PITR window, to your Amazon S3 bucket.
- With **filtered export**, you can export a subset of your DynamoDB table data instead of the entire table. You can apply a filter to both full exports and incremental exports. For more information about how filtered export works, see Filtering a table export.

Topics

- Prerequisites
- Requesting an export using the AWS Management Console
- Getting details about past exports in the AWS Management Console
- Requesting an export using the AWS CLI and AWS SDKs
- Getting details about past exports using the AWS CLI and AWS SDKs

Prerequisites

Enable PITR

To use the export to S3 feature, you must enable PITR on your table. For details about how to enable PITR, see Point-in-time recovery. If you request an export for a table that doesn't have PITR enabled, your request will fail with an exception message: “An error occurred (PointInTimeRecoveryUnavailableException) when calling the `ExportTableToPointInTime` operation: Point in time recovery is not enabled for table 'my-dynamodb-table”. You can only request and export from a point in time that is within your configured PITR `RecoveryPeriodInDays`.

Set up S3 permissions

You can export your table data to any Amazon S3 bucket you have permission to write to. The destination bucket doesn't need to be in the same AWS Region or have the same owner as the source table owner. Your AWS Identity and Access Management (IAM) policy needs to allow you to be able to perform S3 actions (`s3:AbortMultipartUpload`, `s3:PutObject`, and `s3:PutObjectAcl`) and the DynamoDB export action (`dynamodb:ExportTableToPointInTime`). Here's an example of a sample policy that will grant your user permissions to perform exports to an S3 bucket.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDynamoDBExportAction",
            "Effect": "Allow",
            "Action": "dynamodb:ExportTableToPointInTime",
            "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/my-table"
        },
        {
            "Sid": "AllowS3BucketWrites",
            "Effect": "Allow",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
```

```
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

If you need to write to an Amazon S3 bucket that is in another account or you don't have permissions to write to, the Amazon S3 bucket owner must add a bucket policy to allow you to export from DynamoDB to that bucket. Here's an example policy on the target Amazon S3 bucket.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "ExampleStatement",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Revoking these permissions while an export is in progress will result in partial files.

Note

You must call `ExportTableToPointInTime` as a principal in the same AWS account as the source table. Although the destination bucket can belong to a different account (as described earlier), the export request itself must originate from the table's account. A request made from a different account fails with a `ValidationException`: "This action is only supported by accounts that match the resource owner's account." To export a table

that is owned by another account, assume an IAM role in the table's account and make the export request with that role's credentials. When that role writes to a bucket in a different account, include the bucket owner and grant the role write access in the bucket policy as described above.

Note

If the table or bucket you're exporting to is encrypted with customer managed keys, that KMS key's policies must give DynamoDB permission to use it. This permission is given through the IAM User/Role that triggers the export job. For more information on encryption including best practices, see How DynamoDB uses AWS KMS and Using a custom KMS key.

Requesting an export using the AWS Management Console

The following example demonstrates how to use the DynamoDB console to export an existing table named `MusicCollection`.

Note

This procedure assumes that you have enabled point-in-time recovery. To enable it for the `MusicCollection` table, on the table's **Overview** tab, in the **Table details** section, choose **Enable** for **Point-in-time recovery**.

To request a table export

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Exports to S3**.
3. Select the **Export to S3** button.
4. Choose a source table and destination S3 bucket. If the destination bucket is owned by your account, you can use the **Browse S3** button to find it. Otherwise, enter the URL of the bucket using the `s3://`**`bucketname`**`/`**`prefix`** `format.` the **`prefix`** is an optional folder to help keep your destination bucket organized.

5. Choose **Full export** or **Incremental export**. A **full export** outputs the full table snapshot of your table as it was at the point in time you specify. An **incremental export** outputs the changes made to your table during the specified export period. Your output is compacted so it only contains the final state of the item from the export period. The item will only appear once in the export even if it has multiple updates within the same export period.

   Full export

   1. Select the point in time you want to export the full table snapshot from. This can be any point in time within the PITR window. Alternatively, you can select **Current time** to export the latest snapshot.
   2. For **Exported file format**, choose between **DynamoDB JSON** and **Amazon Ion**. By default, your table will be exported in DynamoDB JSON format from the latest restorable time in the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3). You can change these export settings if necessary.

      > **Note**
      >
      > If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

   Incremental export

   1. Select the **Export period** you want to export the incremental data for. Pick a start time within the PITR window. The export period duration must be at least 15 minutes and be no longer than 24 hours. The export period's start time is inclusive and the end time is exclusive.
   2. Choose between **Absolute mode** or **Relative mode**.
      a. **Absolute mode** will export incremental data for the time period you specify.
      b. **Relative mode** will export incremental data for an export period that is relative to your export job submission time.
   3. For **Exported file format**, choose between **DynamoDB JSON** and **Amazon Ion**. By default, your table will be exported in DynamoDB JSON format from the latest

restorable time in the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3). You can change these export settings if necessary.

> **Note**
>
> If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

4. For **Export view type**, select either **New and old images** or **New images only**. New image provides the latest state of the item. Old image provides the state of the item right before the specified “start date and time”. The default setting is **New and old images**. For more information on new images and old images, see Incremental export output.

6. (Optional) To export only a subset of your table data, specify a filter for the export. You can provide a filter expression for any attributes, a key condition expression to select items by their partition key value, and a projection expression to choose which attributes to include in the output. For more information about how these expressions work and how they affect the data processed, see Filtering a table export.
7. Choose **Export** to begin.

Exported data isn't transactionally consistent. Your transaction operations can be torn between two export outputs. A subset of items can be modified by a transaction operation reflected in the export, while another subset of modifications in the same transaction isn't reflected in the same export request. However, exports are eventually consistent. If a transaction is torn during an export, you'll have the remaining transaction in your next contiguous export, without duplicates. The time periods used for exports are based on an internal system clock and can vary by one minute of your application’s local clock.

Getting details about past exports in the AWS Management Console

You can find information about export tasks you've run in the past by choosing the **Exports to S3** section in the navigation sidebar. This section contains a list of all exports you've created in the past 90 days. Select the ARN of a task listed in the **Exports** tab to retrieve information about that export, including any advanced configuration settings you chose. Note that although export task metadata expires after 90 days and jobs older than that are no longer found in this list, the objects

in your S3 bucket remain as long as their bucket policies allow. DynamoDB never deletes any of the objects it creates in your S3 bucket during an export.

Requesting an export using the AWS CLI and AWS SDKs

The following examples show how to export an existing table to an S3 bucket.

> **Note**
>
> This procedure assumes that you have enabled point-in-time recovery. To enable it for the `MusicCollection` table, run the following command.
>
> ```
> aws dynamodb update-continuous-backups \
>     --table-name MusicCollection \
>     --point-in-time-recovery-specification PointInTimeRecoveryEnabled=True
> ```

Full export

AWS CLI

> **Note**
>
> If requesting a cross-account table export, make sure to include the `--s3-bucket-owner` option.

```
aws dynamodb export-table-to-point-in-time \
  --table-arn arn:aws:dynamodb:us-west-2:111122223333:table/MusicCollection \
  --s3-bucket ddb-export-musiccollection-9012345678 \
  --s3-prefix 2020-Nov \
  --export-format DYNAMODB_JSON \
  --export-time 1604632434 \
  --s3-bucket-owner 9012345678 \
  --s3-sse-algorithm AES256
```

Python

```
import boto3
from datetime import datetime
```

```
client = boto3.client('dynamodb')

client.export_table_to_point_in_time(
    TableArn='arn:aws:dynamodb:us-east-1:111122223333:table/TABLE',
    ExportTime=datetime(2023, 9, 20, 12, 0, 0),
    S3Bucket='bucket',
    S3Prefix='prefix',
    S3SseAlgorithm='AES256',
    ExportFormat='DYNAMODB_JSON'
)
```

Java

```
DynamoDbClient client = DynamoDbClient.create();

client.exportTableToPointInTime(b -> b
    .tableArn("arn:aws:dynamodb:us-east-1:111122223333:table/TABLE")
    .exportTime(Instant.parse("2023-09-20T12:00:00Z"))
    .s3Bucket("bucket")
    .s3Prefix("prefix")
    .s3SseAlgorithm(S3SseAlgorithm.AES256)
    .exportFormat(ExportFormat.DYNAMODB_JSON));
```

.NET

```
var client = new AmazonDynamoDBClient();

await client.ExportTableToPointInTimeAsync(new ExportTableToPointInTimeRequest
{
    TableArn = "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE",
    ExportTime = new DateTime(2023, 9, 20, 12, 0, 0, DateTimeKind.Utc),
    S3Bucket = "bucket",
    S3Prefix = "prefix",
    S3SseAlgorithm = S3SseAlgorithm.AES256,
    ExportFormat = ExportFormat.DYNAMODB_JSON
});
```

JavaScript

```
import { DynamoDBClient, ExportTableToPointInTimeCommand } from "@aws-sdk/client-
dynamodb";
```

```
const client = new DynamoDBClient();

await client.send(new ExportTableToPointInTimeCommand({
    TableArn: "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE",
    ExportTime: new Date("2023-09-20T12:00:00Z"),
    S3Bucket: "bucket",
    S3Prefix: "prefix",
    S3SseAlgorithm: "AES256",
    ExportFormat: "DYNAMODB_JSON"
}));
```

Go

```
cfg, _ := config.LoadDefaultConfig(context.TODO())
client := dynamodb.NewFromConfig(cfg)

exportTime := time.Date(2023, 9, 20, 12, 0, 0, 0, time.UTC)
client.ExportTableToPointInTime(context.TODO(),
 &dynamodb.ExportTableToPointInTimeInput{
    TableArn:       aws.String("arn:aws:dynamodb:us-east-1:111122223333:table/
TABLE"),
    ExportTime:     &exportTime,
    S3Bucket:       aws.String("bucket"),
    S3Prefix:       aws.String("prefix"),
    S3SseAlgorithm: types.S3SseAlgorithmAes256,
    ExportFormat:   types.ExportFormatDynamodbJson,
})
```

Incremental export

AWS CLI

```
aws dynamodb export-table-to-point-in-time \
  --table-arn arn:aws:dynamodb:REGION:ACCOUNT:table/TABLENAME \
  --s3-bucket BUCKET --s3-prefix PREFIX \
  --incremental-export-specification
 ExportFromTime=1693569600,ExportToTime=1693656000,ExportViewType=NEW_AND_OLD_IMAGES
 \
  --export-type INCREMENTAL_EXPORT
```

Python

```
import boto3
from datetime import datetime

client = boto3.client('dynamodb')

client.export_table_to_point_in_time(
    TableArn='arn:aws:dynamodb:us-east-1:111122223333:table/TABLE',
    IncrementalExportSpecification={
      'ExportFromTime': datetime(2023, 9, 20, 12, 0, 0),
      'ExportToTime': datetime(2023, 9, 20, 13, 0, 0),
      'ExportViewType': 'NEW_AND_OLD_IMAGES'
    },
    ExportType='INCREMENTAL_EXPORT',
    S3Bucket='bucket',
    S3Prefix='prefix',
    S3SseAlgorithm='AES256',
    ExportFormat='DYNAMODB_JSON'
)
```

Java

```
DynamoDbClient client = DynamoDbClient.create();

client.exportTableToPointInTime(b -> b
    .tableArn("arn:aws:dynamodb:us-east-1:111122223333:table/TABLE")
    .exportType(ExportType.INCREMENTAL_EXPORT)
    .incrementalExportSpecification(i -> i
        .exportFromTime(Instant.parse("2023-09-20T12:00:00Z"))
        .exportToTime(Instant.parse("2023-09-20T13:00:00Z"))
        .exportViewType(ExportViewType.NEW_AND_OLD_IMAGES))
    .s3Bucket("bucket")
    .s3Prefix("prefix")
    .s3SseAlgorithm(S3SseAlgorithm.AES256)
    .exportFormat(ExportFormat.DYNAMODB_JSON));
```

.NET

```
var client = new AmazonDynamoDBClient();

await client.ExportTableToPointInTimeAsync(new ExportTableToPointInTimeRequest
{
```

```
    TableArn = "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE",
    ExportType = ExportType.INCREMENTAL_EXPORT,
    IncrementalExportSpecification = new IncrementalExportSpecification
    {
        ExportFromTime = new DateTime(2023, 9, 20, 12, 0, 0, DateTimeKind.Utc),
        ExportToTime = new DateTime(2023, 9, 20, 13, 0, 0, DateTimeKind.Utc),
        ExportViewType = ExportViewType.NEW_AND_OLD_IMAGES
    },

        ExportToTime:   &toTime,
        ExportViewType: types.ExportViewTypeNewAndOldImages,
    },
    S3Bucket:       aws.String("bucket"),
    S3Prefix:       aws.String("prefix"),
    S3SseAlgorithm: types.S3SseAlgorithmAes256,
    ExportFormat:   types.ExportFormatDynamodbJson,
})
```

Filtered export

The following examples export a subset of a table by including a `FilterSpecification` on the export request. Each example uses a key condition expression to select a single partition key value, a filter expression to match a non-key attribute, and a projection expression to choose the attributes in the output. You can apply a `FilterSpecification` to a full export or an incremental export. An expression can be up to 4 KB in size, an attribute name can be up to 250 bytes, an attribute value can be up to 2 MB, and an expression can contain at most 300 operators. When you provide a key condition expression, the partition key can't also appear in the filter expression. For more information, see Filtering a table export.

AWS CLI

```
aws dynamodb export-table-to-point-in-time \
  --table-arn arn:aws:dynamodb:us-east-1:111122223333:table/MusicCollection \
  --s3-bucket ddb-export-musiccollection-9012345678 \
  --s3-prefix 2020-Nov \
  --export-format DYNAMODB_JSON \
  --export-time 1604632434 \
  --s3-sse-algorithm AES256 \
  --filter-specification '{
    "KeyConditionExpression": "customer_id = :cid",
    "FilterExpression": "#tier = :premium",
    "ProjectionExpression": "customer_id, #tier",
    "ExpressionAttributeNames": {"#tier": "tier"},
```

```
    "ExpressionAttributeValues": {":cid": {"S": "cust-123"}, ":premium": {"S":
 "premium"}}
  }'
```

Python

```
import boto3
from datetime import datetime

client = boto3.client('dynamodb')

client.export_table_to_point_in_time(
    TableArn='arn:aws:dynamodb:us-east-1:111122223333:table/TABLE',
    ExportTime=datetime(2023, 9, 20, 12, 0, 0),
    S3Bucket='bucket',
    S3Prefix='prefix',
    S3SseAlgorithm='AES256',
    ExportFormat='DYNAMODB_JSON',
    FilterSpecification={
        'KeyConditionExpression': 'customer_id = :cid',
        'FilterExpression': '#tier = :premium',
        'ProjectionExpression': 'customer_id, #tier',
        'ExpressionAttributeNames': {'#tier': 'tier'},
        'ExpressionAttributeValues': {
            ':cid': {'S': 'cust-123'},
            ':premium': {'S': 'premium'}
        }
    }
)
```

Java

```
DynamoDbClient client = DynamoDbClient.create();

client.exportTableToPointInTime(b -> b
    .tableArn("arn:aws:dynamodb:us-east-1:111122223333:table/TABLE")
    .exportTime(Instant.parse("2023-09-20T12:00:00Z"))
    .s3Bucket("bucket")
    .s3Prefix("prefix")
    .s3SseAlgorithm(S3SseAlgorithm.AES256)
    .exportFormat(ExportFormat.DYNAMODB_JSON)
    .filterSpecification(f -> f
        .keyConditionExpression("customer_id = :cid")
```

```
        .filterExpression("#tier = :premium")
        .projectionExpression("customer_id, #tier")
        .expressionAttributeNames(Map.of("#tier", "tier"))
        .expressionAttributeValues(Map.of(
            ":cid", AttributeValue.fromS("cust-123"),
            ":premium", AttributeValue.fromS("premium"))));
```

.NET

```
var client = new AmazonDynamoDBClient();

await client.ExportTableToPointInTimeAsync(new ExportTableToPointInTimeRequest
{
    TableArn = "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE",
    ExportTime = new DateTime(2023, 9, 20, 12, 0, 0, DateTimeKind.Utc),
    S3Bucket = "bucket",
    S3Prefix = "prefix",
    S3SseAlgorithm = S3SseAlgorithm.AES256,
    ExportFormat = ExportFormat.DYNAMODB_JSON,
    FilterSpecification = new FilterSpecification
    {
        KeyConditionExpression = "customer_id = :cid",
        FilterExpression = "#tier = :premium",
        ProjectionExpression = "customer_id, #tier",
        ExpressionAttributeNames = new Dictionary<string, string>
        {
            { "#tier", "tier" }
        },
        ExpressionAttributeValues = new Dictionary<string, AttributeValue>
        {
            { ":cid", new AttributeValue { S = "cust-123" } },
            { ":premium", new AttributeValue { S = "premium" } }
        }
    }
});
```

JavaScript

```
import { DynamoDBClient, ExportTableToPointInTimeCommand } from "@aws-sdk/client-
dynamodb";

const client = new DynamoDBClient();
```

```
await client.send(new ExportTableToPointInTimeCommand({
    TableArn: "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE",
    ExportTime: new Date("2023-09-20T12:00:00Z"),
    S3Bucket: "bucket",
    S3Prefix: "prefix",
    S3SseAlgorithm: "AES256",
    ExportFormat: "DYNAMODB_JSON",
    FilterSpecification: {
        KeyConditionExpression: "customer_id = :cid",

        ProjectionExpression:   aws.String("customer_id, #tier"),
        ExpressionAttributeNames: map[string]string{
            "#tier": "tier",
        },
        ExpressionAttributeValues: map[string]types.AttributeValue{
            ":cid":     &types.AttributeValueMemberS{Value: "cust-123"},
```

```
            ":premium": &types.AttributeValueMemberS{Value: "premium"},
        },
    },
})
```

> **Note**
>
> DynamoDB validates your expressions before a filtered export starts. If you provide a `FilterSpecification` without any expression, or if an expression is invalid, the request fails with a `ValidationException`. The `DescribeExport` operation returns the `FilterSpecification` that you applied to an export. The `ListExports` operation is unchanged, and filtering doesn't introduce a new export type. The export type (`FULL_EXPORT` or `INCREMENTAL_EXPORT`) still determines when data is exported. The filter determines what data is exported.

> **Note**
>
> If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

Getting details about past exports using the AWS CLI and AWS SDKs

You can find information about export requests you've run in the past by using the `list-exports` command. This command returns a list of all exports you've created in the past 90 days. Note that although export task metadata expires after 90 days and jobs older than that are no longer returned by the `list-exports` command, the objects in your S3 bucket remain as long as their bucket policies allow. DynamoDB never deletes any of the objects it creates in your S3 bucket during an export.

Exports have a status of `PENDING` until they either succeed or fail. If they succeed, the status changes to `COMPLETED`. If they fail, the status changes to `FAILED` with a `failure_message` and `failure_reason`.

List exports

AWS CLI

```
aws dynamodb list-exports \
    --table-arn arn:aws:dynamodb:us-east-1:111122223333:table/ProductCatalog
```

Python

```
import boto3

client = boto3.client('dynamodb')

print(
  client.list_exports(
     TableArn='arn:aws:dynamodb:us-east-1:111122223333:table/TABLE',
  )
)
```

Java

```
DynamoDbClient client = DynamoDbClient.create();

ListExportsResponse response = client.listExports(b -> b
    .tableArn("arn:aws:dynamodb:us-east-1:111122223333:table/TABLE"));

response.exportSummaries().forEach(System.out::println);
```

.NET

```
var client = new AmazonDynamoDBClient();

var response = await client.ListExportsAsync(new ListExportsRequest
{
    TableArn = "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE"
});

response.ExportSummaries.ForEach(Console.WriteLine);
```

JavaScript

```
import { DynamoDBClient, ListExportsCommand } from "@aws-sdk/client-dynamodb";
```

```
const client = new DynamoDBClient();

const response = await client.send(new ListExportsCommand({
    TableArn: "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE"
}));

console.log(response.ExportSummaries);
```

Go

```
cfg, _ := config.LoadDefaultConfig(context.TODO())
client := dynamodb.NewFromConfig(cfg)

response, _ := client.ListExports(context.TODO(), &dynamodb.ListExportsInput{
    TableArn: aws.String("arn:aws:dynamodb:us-east-1:111122223333:table/TABLE"),
})

fmt.Println(response.ExportSummaries)
```

Describe export

AWS CLI

```
aws dynamodb describe-export \
    --export-arn arn:aws:dynamodb:us-east-1:111122223333:table/ProductCatalog/
export/01695353076000-a1b2c3d4
```

Python

```
import boto3

client = boto3.client('dynamodb')

print(
  client.describe_export(
     ExportArn='arn:aws:dynamodb:us-east-1:111122223333:table/TABLE/
export/01695353076000-06e2188f',
  )['ExportDescription']
)
```

Java

```
DynamoDbClient client = DynamoDbClient.create();

DescribeExportResponse response = client.describeExport(b -> b
    .exportArn("arn:aws:dynamodb:us-east-1:111122223333:table/TABLE/
export/01695353076000-06e2188f"));

System.out.println(response.exportDescription());
```

.NET

```
var client = new AmazonDynamoDBClient();

var response = await client.DescribeExportAsync(new DescribeExportRequest
{
    ExportArn = "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE/
export/01695353076000-06e2188f"
});

Console.WriteLine(response.ExportDescription);
```

JavaScript

```
import { DynamoDBClient, DescribeExportCommand } from "@aws-sdk/client-dynamodb";

const client = new DynamoDBClient();

const response = await client.send(new DescribeExportCommand({
    ExportArn: "arn:aws:dynamodb:us-east-1:111122223333:table/TABLE/
export/01695353076000-06e2188f"
}));

console.log(response.ExportDescription);
```

Go

```
cfg, _ := config.LoadDefaultConfig(context.TODO())
client := dynamodb.NewFromConfig(cfg)

response, _ := client.DescribeExport(context.TODO(), &dynamodb.DescribeExportInput{
```

```
    ExportArn: aws.String("arn:aws:dynamodb:us-east-1:111122223333:table/TABLE/
export/01695353076000-06e2188f"),
})

fmt.Println(response.ExportDescription)
```

Filtering a table export

Instead of exporting an entire table, you can export only the items and attributes that you need. DynamoDB exports only the data that matches the expressions you provide. Filtered export works with both full exports and incremental exports.

For an incremental export, DynamoDB evaluates the filter against the latest image of each changed item. For a deleted item, DynamoDB evaluates the filter against the old image of the item, because the new image doesn't exist.

You control what a filtered export returns with three types of expressions. You can provide one of them or combine them in a single export request:

- A **key condition expression** selects items by their primary key, using the same syntax and rules as a DynamoDB `Query` key condition expression. A key condition expression specifies a single partition key value with an equality comparison, and an optional condition on the sort key. It can't reference non-key attributes, and it can't specify more than one partition key value. Because a key condition expression limits the export to a single partition key value, it reduces the amount of data that DynamoDB reads for the export. For more information, see Key condition expressions for the Query operation in DynamoDB.
- A **filter expression** can apply conditions to both key and non-key attributes, using the same syntax and rules as a filter expression in a `Scan` operation. Filter expressions support comparisons such as equals, not equals, and `OR`, along with the `contains`, `IN`, `begins_with`, `BETWEEN`, `attribute_exists`, and `size` functions. DynamoDB applies a filter expression after it reads the data, so the filter doesn't reduce the amount of data that DynamoDB processes for the export. For more information about filter expressions and their syntax, see Syntax for filter and condition expressions.
- A **projection expression** identifies the specific attributes that you want in the export output, using the same syntax and rules as a projection expression in other DynamoDB operations. For more information, see Using projection expressions in DynamoDB.

> **Note**
>
> Whether a key attribute can appear in the filter expression depends on whether you also provide a key condition expression. If you provide a key condition expression, the key attribute can't also appear in the filter expression. If you provide only a filter expression, key attributes can appear in the filter expression.

Each expression is subject to the following limits:

- An expression can be up to 4 KB in size.
- Attribute names can be up to 250 bytes.
- Attribute values can be up to 2 MB.
- An expression can contain at most 300 operators.

DynamoDB table export output format

A DynamoDB table export includes manifest files in addition to the files containing your table data. These files are all saved in the Amazon S3 bucket that you specify in your export request. The following sections describe the format and contents of each output object.

Full export output

Manifest files

DynamoDB creates manifest files, along with their checksum files, in the specified S3 bucket for each export request.

```
export-prefix/AWSDynamoDB/ExportId/manifest-summary.json
export-prefix/AWSDynamoDB/ExportId/manifest-summary.checksum
export-prefix/AWSDynamoDB/ExportId/manifest-files.json
export-prefix/AWSDynamoDB/ExportId/manifest-files.checksum
```

You choose an **`export-prefix`** when you request a table export. This helps you keep files in the destination S3 bucket organized. The **`ExportId`** is a unique token generated by the service to make sure that multiple exports to the same S3 bucket and `export-prefix` don't overwrite each other.

The export creates at least 1 file per partition. For partitions that are empty, your export request will create an empty file. All of the items in each file are from that particular partition's hashed keyspace.

> **Note**
>
> DynamoDB also creates an empty file named `_started` in the same directory as the manifest files. This file verifies that the destination bucket is writable and that the export has begun. It can safely be deleted.

The summary manifest

The `manifest-summary.json` file contains summary information about the export job. This allows you to know which data files in the shared data folder are associated with this export. Its format is as follows:

```
{
   "version": "2020-06-30",
   "exportArn": "arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/
export/01234567890123-a1b2c3d4",
   "startTime": "2020-11-04T07:28:34.028Z",
   "endTime": "2020-11-04T07:33:43.897Z",
   "tableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog",
   "tableId": "12345a12-abcd-123a-ab12-1234abc12345",
   "exportTime": "2020-11-04T07:28:34.028Z",
   "s3Bucket": "ddb-productcatalog-export",
   "s3Prefix": "2020-Nov",
   "s3SseAlgorithm": "AES256",
   "s3SseKmsKeyId": null,
   "manifestFilesS3Key": "AWSDynamoDB/01693685827463-2d8752fd/manifest-files.json",
   "billedSizeBytes": 0,
   "itemCount": 8,
   "outputFormat": "DYNAMODB_JSON"
}
```

> **Note**
>
> The `exportType` field is present in the `manifest-summary.json` file only for incremental exports, where it has a value of `INCREMENTAL_EXPORT`. It is not included in the summary manifest for full exports.

> **Note**
>
> If the export request included a filter, the summary manifest also includes the filter specification that was applied.

The files manifest

The `manifest-files.json` file contains information about the files that contain your exported table data. The file is in JSON lines format, so newlines are used as item delimiters. In the following example, the details of one data file from a files manifest are formatted on multiple lines for the sake of readability.

```
{
"itemCount": 8,
   "md5Checksum": "sQMSpEILNgoQmarvDFonGQ==",
   "etag": "af83d6f217c19b8b0fff8023d8ca4716-1",
   "dataFileS3Key": "AWSDynamoDB/01693685827463-2d8752fd/data/asdl123dasas.json.gz"
}
```

Data files

DynamoDB can export your table data in two formats: DynamoDB JSON and Amazon Ion. Regardless of the format you choose, your data will be written to multiple compressed files named by the keys. These files are also listed in the `manifest-files.json` file.

The directory structure of your Amazon S3 bucket after a full export will contain all of your manifest files and data files under the export Id folder.

```
amzn-s3-demo-bucket/DestinationPrefix
.
### AWSDynamoDB
```

```
    ### 01693685827463-2d8752fd     // the single full export
    #   ### manifest-files.json     // manifest points to files under 'data' subfolder
    #   ### manifest-files.checksum
    #   ### manifest-summary.json   // stores metadata about request
    #   ### manifest-summary.md5
    #   ### data                    // The data exported by full export
    #   #   ### asdl123dasas.json.gz
    #   #   ...
    #   ### _started                // empty file for permission check
```

DynamoDB JSON

A table export in DynamoDB JSON format consists of multiple `Item` objects. Each individual object is in DynamoDB's standard marshalled JSON format.

When creating custom parsers for DynamoDB JSON export data, the format is JSON lines. This means that newlines are used as item delimiters. Many AWS services, such as Athena and AWS Glue, will parse this format automatically.

In the following example, a single item from a DynamoDB JSON export has been formatted on multiple lines for the sake of readability.

```
{
    "Item":{
        "Authors":{
            "SS":[
                "Author1",
                "Author2"
            ]
        },
        "Dimensions":{
            "S":"8.5 x 11.0 x 1.5"
        },
        "ISBN":{
            "S":"333-3333333333"
        },
        "Id":{
            "N":"103"
        },
        "InPublication":{
            "BOOL":false
        },
        "PageCount":{
```

```
            "N":"600"
        },
        "Price":{
            "N":"2000"
        },
        "ProductCategory":{
            "S":"Book"
        },
        "Title":{
            "S":"Book 103 Title"
        }
    }
}
```

Amazon Ion

Amazon Ion is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures. DynamoDB supports exporting table data in Ion's text format, which is a superset of JSON.

When you export a table to Ion format, the DynamoDB datatypes used in the table are mapped to Ion datatypes. DynamoDB sets use Ion type annotations to disambiguate the datatype used in the source table.

The following table lists the mapping of DynamoDB data types to ion data types:

DynamoDB data type	Ion representation
String (S)	string
Boolean (BOOL)	bool
Number (N)	decimal
Binary (B)	blob
Set (SS, NS, BS)	list (with type annotation $dynamodb_SS, $dynamodb_NS, or $dynamodb_BS)
List	list

DynamoDB data type	Ion representation
Map	struct

Items in an Ion export are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format. In the following example, an item from an Ion export has been formatted on multiple lines for the sake of readability.

```
$ion_1_0 {
    Item:{
        Authors:$dynamodb_SS::["Author1","Author2"],
        Dimensions:"8.5 x 11.0 x 1.5",
        ISBN:"333-3333333333",
        Id:103.,
        InPublication:false,
        PageCount:6d2,
        Price:2d3,
        ProductCategory:"Book",
        Title:"Book 103 Title"
    }
}
```

Incremental export output

Manifest files

DynamoDB creates manifest files, along with their checksum files, in the specified S3 bucket for each export request.

```
export-prefix/AWSDynamoDB/ExportId/manifest-summary.json
export-prefix/AWSDynamoDB/ExportId/manifest-summary.checksum
export-prefix/AWSDynamoDB/ExportId/manifest-files.json
export-prefix/AWSDynamoDB/ExportId/manifest-files.checksum
```

You choose an **`export-prefix`** when you request a table export. This helps you keep files in the destination S3 bucket organized. The **`ExportId`** is a unique token generated by the service to make sure that multiple exports to the same S3 bucket and `export-prefix` don't overwrite each other.

The export creates at least 1 file per partition. For partitions that are empty, your export request will create an empty file. All of the items in each file are from that particular partition's hashed keyspace.

> **Note**
>
> DynamoDB also creates an empty file named `_started` in the same directory as the manifest files. This file verifies that the destination bucket is writable and that the export has begun. It can safely be deleted.

The summary manifest

The `manifest-summary.json` file contains summary information about the export job. This allows you to know which data files in the shared data folder are associated with this export. Its format is as follows:

```
{
 "version": "2023-08-01",
 "exportArn": "arn:aws:dynamodb:us-east-1:599882009758:table/export-test/
export/01695097218000-d6299cbd",
 "startTime": "2023-09-19T04:20:18.000Z",
 "endTime": "2023-09-19T04:40:24.780Z",
 "tableArn": "arn:aws:dynamodb:us-east-1:599882009758:table/export-test",
 "tableId": "b116b490-6460-4d4a-9a6b-5d360abf4fb3",
 "exportFromTime": "2023-09-18T17:00:00.000Z",
 "exportToTime": "2023-09-19T04:00:00.000Z",
 "s3Bucket": "jason-exports",
 "s3Prefix": "20230919-prefix",
 "s3SseAlgorithm": "AES256",
 "s3SseKmsKeyId": null,
 "manifestFilesS3Key": "20230919-prefix/AWSDynamoDB/01693685934212-ac809da5/manifest-
files.json",
 "billedSizeBytes": 20901239349,
 "itemCount": 169928274,
 "outputFormat": "DYNAMODB_JSON",
 "outputView": "NEW_AND_OLD_IMAGES",
 "exportType": "INCREMENTAL_EXPORT"
}
```

The files manifest

The `manifest-files.json` file contains information about the files that contain your exported table data. The file is in JSON lines format, so newlines are used as item delimiters. In the following example, the details of one data file from a files manifest are formatted on multiple lines for the sake of readability.

```
{
"itemCount": 8,
   "md5Checksum": "sQMSpEILNgoQmarvDFonGQ==",
   "etag": "af83d6f217c19b8b0fff8023d8ca4716-1",
   "dataFileS3Key": "AWSDynamoDB/data/sgad6417s6vss4p7owp0471bcq.json.gz"
}
```

Data files

DynamoDB can export your table data in two formats: DynamoDB JSON and Amazon Ion. Regardless of the format you choose, your data will be written to multiple compressed files named by the keys. These files are also listed in the `manifest-files.json` file.

The data files for incremental exports are all contained in a common data folder in your S3 bucket. Your manifest files are under your export ID folder.

```
amzn-s3-demo-bucket/DestinationPrefix
.
### AWSDynamoDB
    ### 01693685934212-ac809da5     // an incremental export ID
    #   ### manifest-files.json     // manifest points to files under 'data' folder
    #   ### manifest-files.checksum
    #   ### manifest-summary.json   // stores metadata about request
    #   ### manifest-summary.md5
    #   ### _started               // empty file for permission check
    ### 01693686034521-ac809da5
    #   ### manifest-files.json
    #   ### manifest-files.checksum
    #   ### manifest-summary.json
    #   ### manifest-summary.md5
    #   ### _started
    ### data                       // stores all the data files for incremental
 exports
    #   ### sgad6417s6vss4p7owp0471bcq.json.gz
    #   ...
```

In your export files, each item's output includes a timestamp that represents when that item was updated in your table and a data structure that indicates if it was an `insert`, `update`, or `delete` operation. The timestamp is based on an internal system clock and can vary from your application clock. For incremental exports, you can choose between two export view types for your output structure: **new and old images** or **new images only**.

- **New image** provides the latest state of the item
- **Old image** provides the state of the item right before the specified **start date and time**

View types can be helpful if you want to see how the item was changed within the export period. It can also be useful for efficiently updating your downstream systems, especially if those downstream systems have a partition key that is not the same as your DynamoDB partition key.

You can infer whether an item in your incremental export output was an `insert`, `update`, or `delete` by looking at the structure of the output. The incremental export structure and its corresponding operations are summarized in the table below for both export view types.

Operation	New images only	New and old images
Insert	Keys + new image	Keys + new image
Update	Keys + new image	Keys + new image + old image
Delete	Keys	Keys + old image
Insert + delete	No output	No output

DynamoDB JSON

A table export in DynamoDB JSON format consists of a metadata timestamp that indicates the write time of the item, followed by the keys of the item and the values. The following shows an example DynamoDB JSON output using export view type as **New and Old images**.

```
// Ex 1: Insert
//   An insert means the item did not exist before the incremental export window
//   and was added during the incremental export window
```

```
{
   "Metadata": {
     "WriteTimestampMicros": {
       "N": "1680109764000000"
     }
   },
   "Keys": {
     "PK": {
       "S": "CUST#100"
     }
   },
   "NewImage": {
     "PK": {
       "S": "CUST#100"
     },
     "FirstName": {
       "S": "John"
     },
     "LastName": {
       "S": "Don"
     }
   }
}

// Ex 2: Update
//   An update means the item existed before the incremental export window
//   and was updated during the incremental export window.
//   The OldImage would not be present if choosing "New images only".

{
   "Metadata": {
     "WriteTimestampMicros": {
       "N": "1680109764000000"
     }
   },
   "Keys": {
     "PK": {
       "S": "CUST#200"
     }
   },
   "OldImage": {
     "PK": {
       "S": "CUST#200"
     },
```

```
      "FirstName": {
        "S": "Mary"
      },
      "LastName": {
        "S": "Grace"
      }
    },
    "NewImage": {
      "PK": {
        "S": "CUST#200"
      },
      "FirstName": {
        "S": "Mary"
      },
      "LastName": {
        "S": "Smith"
      }
    }
}

// Ex 3: Delete
//   A delete means the item existed before the incremental export window
//   and was deleted during the incremental export window
//   The OldImage would not be present if choosing "New images only".

{
    "Metadata": {
      "WriteTimestampMicros": {
        "N": "1680109764000000"
      }
    },
    "Keys": {
      "PK": {
        "S": "CUST#300"
      }
    },
    "OldImage": {
      "PK": {
        "S": "CUST#300"
      },
      "FirstName": {
        "S": "Jose"
      },
      "LastName": {
```

```
        "S": "Hernandez"
      }
    }
}

// Ex 4: Insert + Delete
//   Nothing is exported if an item is inserted and deleted within the
//   incremental export window.
```

Amazon Ion

Amazon Ion is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures. DynamoDB supports exporting table data in Ion's text format, which is a superset of JSON.

When you export a table to Ion format, the DynamoDB datatypes used in the table are mapped to Ion datatypes. DynamoDB sets use Ion type annotations to disambiguate the datatype used in the source table.

The following table lists the mapping of DynamoDB data types to ion data types:

DynamoDB data type	Ion representation
String (S)	string
Boolean (BOOL)	bool
Number (N)	decimal
Binary (B)	blob
Set (SS, NS, BS)	list (with type annotation $dynamodb_SS, $dynamodb_NS, or $dynamodb_BS)
List	list
Map	struct

Items in an Ion export are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format. In the following example, an item from an Ion export has been formatted on multiple lines for the sake of readability.

```
$ion_1_0 {
    Record:{
        Keys:{
             ISBN:"333-3333333333"
         },
        Metadata:{
            WriteTimestampMicros:1684374845117899.
        },
        OldImage:{
            Authors:$dynamodb_SS::["Author1","Author2"],
            ISBN:"333-3333333333",
            Id:103.,
            InPublication:false,
            ProductCategory:"Book",
            Title:"Book 103 Title"
        },
        NewImage:{
            Authors:$dynamodb_SS::["Author1","Author2"],
            Dimensions:"8.5 x 11.0 x 1.5",
            ISBN:"333-3333333333",
            Id:103.,
            InPublication:true,
            PageCount:6d2,
            Price:2d3,
            ProductCategory:"Book",
            Title:"Book 103 Title"
        }
    }
}
```

DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse eliminates the need to build custom data movement pipelines by automatically replicating DynamoDB data to Amazon SageMaker Lakehouse. This no-code integration helps customers run analytics workloads on their DynamoDB data using Amazon SageMaker Lakehouse without consuming any DynamoDB table

capacity. The integration automatically exports data from your table and keeps the target fresh, typically within 15 to 30 minutes.

Topics

- DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

Setting up an integration between the DynamoDB table and Amazon SageMaker Lakehouse require prerequisites such as configuring IAM roles which AWS Glue uses to access data from the source and write to the target, and the use of KMS keys to encrypt the data in intermediate or the target location.

Topics

- Prerequisites before creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse
- Creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse
- Viewing CloudWatch metrics for integration

Prerequisites before creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

To configure a zero-ETL integration with an DynamoDB source, you need to set up a Resource-Based Access (RBAC) policy that allows AWS Glue to access and export data from the DynamoDB table. The policy should include specific permissions like `ExportTableToPointInTime`, `DescribeTable`, and `DescribeExport` with conditions restricting access to a specific AWS account and region. See, Configuring an Amazon DynamoDB source for more information.

Point-in-time recovery (PITR) must be enabled for the table, and you can apply the policy using AWS CLI commands. The policy can be further refined by specifying the full integration ARN for more restrictive access control. For more information, see Prerequisites for setting up a zero-ETL integration.

Creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

After completing integration prerequisites, you can create, modify, or delete the zero-ETL integration following the guidance below:

Creating an integration

To create an integration

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.
2. In the navigation pane, choose **Integrations**.
3. Select **Create zero-ETL integration with Amazon SageMaker Lakehouse**, and then choose **Next**.
4. To create an integration, see Creating an integration.
5. To modify an integration, see Modifying an integration.
6. To delete an integration, see Deleting an integration.
7. To set up a cross-account integration, see Setting up cross-account integration.

Enabling compaction on target Amazon S3 tables

You can enable compaction to improve query performance in Amazon Athena.

First, complete the prerequisite setup for compaction resources, including configuring the necessary IAM role. Refer to the Lake Formation documentation for detailed IAM role configuration steps. See, Optimizing tables for compaction.

To enable compaction on the AWS Glue table created during integration, follow the Lake Formation compaction enabling process. This will help optimize your table's performance and query efficiency.

Viewing CloudWatch metrics for integration

Once an integration completes, you can see these CloudWatch metrics and EventBridge notifications generated in your account for each AWS Glue job. For more information, see Monitoring an integration.

DynamoDB zero-ETL integration with Amazon OpenSearch Service

Amazon DynamoDB offers a zero-ETL integration with Amazon OpenSearch Service through the **DynamoDB plugin for OpenSearch Ingestion**. Amazon OpenSearch Ingestion offers a fully managed, no-code experience for ingesting data into Amazon OpenSearch Service.

With the DynamoDB plugin for OpenSearch Ingestion, you can use one or more DynamoDB tables as a source for ingestion to one or more OpenSearch Service indexes. You can browse and configure your OpenSearch Ingestion pipelines with DynamoDB as a source from either OpenSearch Ingestion or DynamoDB Integrations in the AWS Management Console.

- Get started with OpenSearch Ingestion by following along in the OpenSearch Ingestion getting started guide.
- Learn about the prerequisites and all the configuration options for the DynamoDB plugin at DynamoDB plugin for OpenSearch Ingestion documentation.

How it works

The plugin uses DynamoDB export to Amazon S3 to create an initial snapshot to load into OpenSearch. After the snapshot has been loaded, the plugin uses DynamoDB Streams to replicate any further changes in near real time. Every item is processed as an event in OpenSearch Ingestion and can be modified with processor plugins. You can drop attributes or create composite attributes and send them to different indexes through routes.

You must have point-in-time recovery (PITR) enabled to use export to Amazon S3. You must also have DynamoDB Streams enabled (with the **new & old images** option selected) to be able to use it. It's possible to create a pipeline without taking a snapshot by excluding export settings.

You can also create a pipeline with only a snapshot and no updates by excluding streams settings. The plugin does not use read or write throughput on your table, so it is safe to use without impacting your production traffic. There are limits to the number of parallel consumers on a stream that you should consider before creating this or other integrations. For other considerations, see the section called “Integration best practices”.

For simple pipelines, a single OpenSearch Compute Unit (OCU) can process about 1 MB per second of writes. This is the equivalent of about 1000 write request units (WCU). Depending on your pipeline's complexity and other factors, you might achieve more or less than this.

OpenSearch Ingestion supports a dead-letter queue (DLQ) for events that cause unrecoverable errors. Additionally, the pipeline can resume from where it left off without user intervention even if there's an interruption of service with either DynamoDB, the pipeline, or Amazon OpenSearch Service.

If interruption goes on for longer than 24 hours, this can cause a loss of updates. However, the pipeline would continue to process the updates that were still available when availability is restored. You would need to do a fresh index build to fix any irregularities due to the dropped events unless they were in the dead-letter queue.

For all the settings and details for the plugin, see OpenSearch Ingestion DynamoDB plugin documentation.

Integrated create experience through the console

DynamoDB and OpenSearch Service have an integrated experience in the AWS Management Console, which streamlines the getting started process. When you go through these steps, the service will automatically select the DynamoDB blueprint and add the appropriate DynamoDB information for you.

To create an integration, follow along in the OpenSearch Ingestion getting started guide. When you get to Step 3: Create a pipeline, replace Steps 1 and 2 with the following steps:

1. Navigate to the DynamoDB console.
2. In the left-hand navigation pane, choose **Integration**.
3. Select the DynamoDB table that you'd like to replicate to OpenSearch.
4. Choose **Create**.

From here, you can continue on with the rest of the tutorial.

Next steps

For a better understanding of how DynamoDB integrates with OpenSearch Service, see the following:

- Getting started with Amazon OpenSearch Ingestion
- DynamoDB plugin configuration and requirements

Handling breaking changes to your index

OpenSearch can dynamically add new attributes to your index. However, after your mapping template has been set for a given key, you'll need to take additional action to change it. Additionally, if your change requires you to reprocess all the data in your DynamoDB table, you'll need to take steps to initiate a fresh export.

> **Note**
>
> In all these options, you might still run into issues if your DynamoDB table has type conflicts with the mapping template you've specified. Make sure that you have a dead-letter queue (DLQ) enabled (even in development). This makes it easier to understand what might be wrong with the record that causes a conflict when it's being indexed into your index on OpenSearch.

Topics

- How it works
- Delete your index and reset the pipeline (pipeline-centric option)
- Recreate your index and reset the pipeline (index-centric option)
- Create a new index and sink (online option)
- Best practices for avoiding and debugging type conflicts

How it works

Here's a quick overview of the actions taken when handling breaking changes to your index. See the step-by-step procedures in the sections that follow.

- **Stop and start the pipeline**: This option resets the pipeline's state, and the pipeline will restart with a new full export. It is non-destructive, so it does **not** delete your index or any data in DynamoDB. If you don't create a fresh index before you do this, you might see a high number of errors from version conflicts because the export tries to insert older documents than the current `_version` in the index. You can safely ignore these errors. You will not be billed for the pipeline while it is stopped.
- **Update the pipeline**: This option updates the configuration in the pipeline with a blue/green approach, without losing any state. If you make significant changes to your pipeline (such as

adding new routes, indexes, or keys to existing indexes), you might need to do a full reset of the pipeline and recreate your index. This option does **not** perform a full export.

- **Delete and recreate the index**: This option removes your data and mapping settings on your index. You should do this before making any breaking changes to your mappings. It will break any applications that rely on the index until the index is recreated and synchronized. Deleting the index does **not** initiate a fresh export. You should delete your index only after you've updated your pipeline. Otherwise, your index might be recreated before you update your settings.

Delete your index and reset the pipeline (pipeline-centric option)

This method is often the fastest option if you're still in development. You'll delete your index in OpenSearch Service, and then stop and start your pipeline to initiate a fresh export of all your data. This ensures that there are no mapping template conflicts with existing indexes, and no loss of data from an incomplete processed table.

1. Stop the pipeline either through the AWS Management Console, or by using the StopPipeline API operation with the AWS CLI or an SDK.
2. Update your pipeline configuration with your new changes.
3. Delete your index in OpenSearch Service, either through a REST API call or your OpenSearch Dashboard.
4. Start the pipeline either through the console, or by using the `StartPipeline` API operation with the AWS CLI or an SDK.

   > **Note**
   >
   > This initiates a fresh full export, which will incur additional costs.

5. Monitor for any unexpected issues because a fresh export is generated to create the new index.
6. Confirm that the index matches your expectations in OpenSearch Service.

After the export has completed and it resumes reading from the stream, your DynamoDB table data will now be available in the index.

Recreate your index and reset the pipeline (index-centric option)

This method works well if you need to do a lot of iterations on the index design in OpenSearch Service before resuming the pipeline from DynamoDB. This can be useful for development when

you want to iterate very quickly on your search patterns, and want to avoid waiting on fresh exports to complete between each iteration.

1. Stop the pipeline either through the AWS Management Console, or by calling the StopPipeline API operation with the AWS CLI or an SDK.
2. Delete and recreate your index in OpenSearch with the mapping template you want to use. You can manually insert some sample data to confirm that your searches are working as intended. If your sample data might conflict with any data from DynamoDB, be sure to delete it before moving onto the next step.
3. If you have an indexing template in your pipeline, remove it or replace it with the one you've created already in OpenSearch Service. Make sure that the name of your index matches the name in the pipeline.
4. Start the pipeline either through console, or by calling the `StartPipeline` API operation with the AWS CLI or an SDK.

   > **Note**
   >
   > This will initiate a fresh full export, which will incur additional costs.

5. Monitor for any unexpected issues because a fresh export is generated to create the new index.

After the export has completed and it resumes reading from the stream, you should be your DynamoDB table data will now be available in the index.

Create a new index and sink (online option)

This method works well if you need to update your mapping template but are currently using your index in production. This creates a brand new index, which you'll need to move your application over to after it's synchronized and validated.

> **Note**
>
> This will create another consumer on the stream. This can be an issue if you also have other consumers like AWS Lambda or global tables. You might need to pause updates to your existing pipeline to create capacity to load the new index.

1. Create a new pipeline with new settings and a different index name.

2. Monitor the new index for any unexpected issues.
3. Swap the application over to the new index.
4. Stop and delete the old pipeline after validating that everything is working correctly.

Best practices for avoiding and debugging type conflicts

- Always use a dead-letter queue (DLQ) to make it easier to debug when there are type conflicts.
- Always use an index template with mappings and set `include_keys`. While OpenSearch Service dynamically maps new keys, this can cause issues with unexpected behaviors (such as expecting something to be a `GeoPoint`, but it's created as a `string` or `object`) or errors (such as having a `number` that is a mix of `long` and `float` values).
- If you need to keep your existing index working in production, you can also replace any of the previous delete index steps with just renaming your index in your pipeline config file. This creates a brand new index. Your application will then need to be updated to point to the new index after it's complete.
- If you have a type conversion issue that you fix with a processor, you can test this with `UpdatePipeline`. To do this, you'll need to do a stop and start or process your dead-letter queues to fix any previously skipped documents that had errors.

Best practices for working with DynamoDB zero-ETL integration and OpenSearch Service

DynamoDB has a DynamoDB zero-ETL integration with Amazon OpenSearch Service. For more information, see the DynamoDB plugin for OpenSearch Ingestion and specific best practices for Amazon OpenSearch Service.

Configuration

- Only index data that you need to perform searches on. Always use a mapping template (`template_type: index_template` and `template_content`) and `include_keys` to implement this.
- Monitor your logs for errors that are related to type conflicts. OpenSearch Service expects all values for a given key to have the same type. It generates exceptions if there's a mismatch. If you encounter one of these errors, you can add a processor to catch that a given key is always be the same value.

- Generally use the `primary_key` metadata value for the `document_id` value. In OpenSearch Service, the document ID is the equivalent of the primary key in DynamoDB. Using the primary key will make it easy to find your document and make sure that updates are consistently replicated to it without conflicts.

  You can use the helper function `getMetadata` to get your primary key (for example, `document_id: "${getMetadata('primary_key')}"`). If you're using a composite primary key, the helper function will concatenate them together for you.
- In general, use the `opensearch_action` metadata value for the `action` setting. This will make sure that updates are replicated in such a way that the data in OpenSearch Service matches the latest state in DynamoDB.

  You can use the helper function `getMetadata` to get your primary key (for example, `action: "${getMetadata('opensearch_action')}"`). You can also get the stream event type through `dynamodb_event_name` for use cases like filtering. However, you should typically not use it for the `action` setting.

Observability

- Always use a dead-letter queue (DLQ) on your OpenSearch sinks to handle dropped events. DynamoDB is generally less structured than OpenSearch Service, and it's always possible for something unexpected to happen. With a dead-letter queue, you can recover individual events, and even automate the recovery process. This will help you to avoid needing to rebuild your entire index.
- Always set alerts that your replication delay doesn't go over an expected amount. It is typically safe to assume one minute without the alert being too noisy. This can vary depending on how spiky your write traffic is and your OpenSearch Compute Unit (OCU) settings on the pipeline.

  If your replication delay goes over 24 hours, your stream will start to drop events, and you'll have accuracy issues unless you do a full rebuild of your index from scratch.

Scaling

- Use auto scaling for pipelines to help scale up or down the OCUs to best fit the workload.

- For provisioned throughput tables without auto scaling, we recommend setting OCUs based on your write capacity units (WCUs) divided by 1000. Set the minimum to 1 OCU below that amount (but at least 1), and set the maximum to at least 1 OCU above that amount.
  - **Formula:**

    ```
    OCU_minimum = GREATEST((table_WCU / 1000) - 1, 1)
    OCU_maximum = (table_WCU / 1000) + 1
    ```

  - **Example:** Your table has 25000 WCUs provisioned. Your pipeline's OCUs should be set with a minimum of 24 (25000/1000 - 1) and maximum of at least 26 (25000/1000 + 1).
- For provisioned throughput tables with auto scaling, we recommend setting OCUs based on your minimum and maximum WCUs, divided by 1000. Set the minimum to 1 OCU below the minimum from DynamoDB, and set the maximum to at least 1 OCU above the maximum from DynamoDB.
  - **Formula:**

    ```
    OCU_minimum = GREATEST((table_minimum_WCU / 1000) - 1, 1)
    OCU_maximum = (table_maximum_WCU / 1000) + 1
    ```

  - **Example:** Your table has an auto scaling policy with a minimum of 8000 and maximum of 14000. Your pipeline's OCUs should be set with a minimum of 7 (8000/1000 - 1) and a maximum of 15 (14000/1000 + 1).
- For on-demand throughput tables, we recommend setting OCUs based on your typical peak and valley for write request units per second. You might need to average over a longer time period, depending on the aggregation that's available to you. Set the minimum to 1 OCU below the minimum from DynamoDB, and set the maximum to at least 1 OCU above the maximum from DynamoDB.
  - **Formula:**

    ```
    # Assuming we have writes aggregated at the minute level
    OCU_minimum = GREATEST((min(table_writes_1min) / (60 * 1000)) - 1, 1)
    OCU_maximum = (max(table_writes_1min) / (60 * 1000)) + 1
    ```

  - **Example:** Your table has an average valley of 300 write request units per second and an average peak of 4300. Your pipeline's OCUs should be set with a minimum of 1 (300/1000 - 1, but at least 1) and a maximum of 5 (4300/1000 + 1).
- Follow best practices on scaling your destination OpenSearch Service indexes. If your indexes are under-scaled, it will slow down ingestion from DynamoDB, and might cause delays.

> **Note**
>
> GREATEST is a SQL function that, given a set of arguments, returns the argument with the greatest value.

Integrating DynamoDB with Amazon EventBridge

Amazon DynamoDB offers DynamoDB Streams for change data capture, enabling the capture of item-level changes in DynamoDB tables. DynamoDB Streams can invoke Lambda functions to process those changes, allowing event driven integration with other services and applications. DynamoDB Streams also supports filtering, which allows for efficient and targeted event processing.

DynamoDB Streams supports up to two simultaneous consumers per shard and supports filtering through Lambda event filtering so that only items which match specific criteria are processed. Some customers may have requirements to support more than two consumers. Others may need to enrich change events before they are processed, or use more advanced filtering and routing.

Integrating DynamoDB with EventBridge can support those requirements.

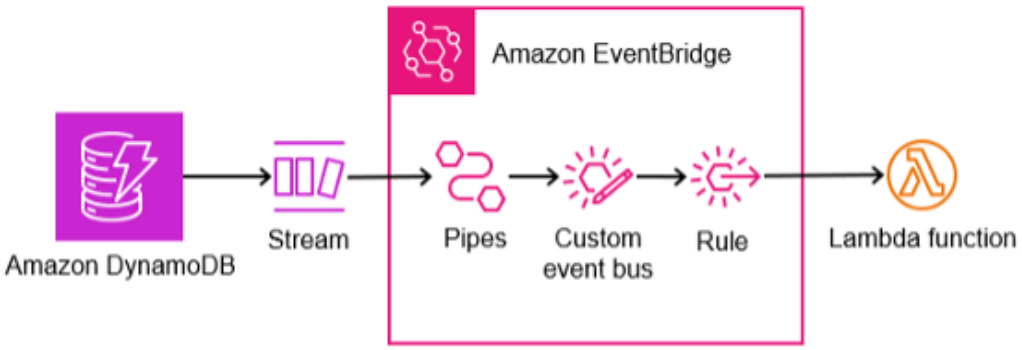
Amazon EventBridge is a serverless service that uses events to connect application components together, making it easier for you to build scalable event-driven applications. EventBridge offers native integration with Amazon DynamoDB through EventBridge Pipes, enabling seamless data flow from DynamoDB to an EventBridge bus. That bus can then fan-out to multiple applications and services through a set of rules and targets.

Topics

- How it works
- Creating an integration through the console
- Next steps

How it works

The integration between DynamoDB and EventBridge pipes uses DynamoDB Streams to capture a time-ordered sequence of item-level changes in a DynamoDB table. Each record captured this way contains the data modified in the table.



An EventBridge pipe consumes events from DynamoDB Streams and routes them to a target such as an EventBridge bus (an event bus is a router that receives events and delivers them to destinations, also called targets). Delivery is based on which rules match the contents of the event. Optionally, the pipe also includes the ability to filter for specific events and perform enrichments on the event data before sending it to the target.

While EventBridge supports multiple target types, a common choice when implementing a fan-out design is to use a Lambda function as the target. The following example demonstrates an integration with a Lambda function target.

Creating an integration through the console

Follow the steps below to create an integration through the AWS Management Console.

1. Enable DynamoDB Streams on the source table by following the steps in the Enabling a stream section of the DynamoDB developer guide. If DynamoDB Streams is already enabled on the source table, verify that there are currently fewer than two consumers. Consumers could be Lambda functions, DynamoDB Global Tables, Amazon DynamoDB zero-ETL integrations with Amazon OpenSearch Service, or applications that read directly from streams such as through the DynamoDB Streams Kinesis adapter.
2. Create an EventBridge event bus by following the steps in the Creating an Amazon EventBridge event bus section of the EventBridge user guide.
   a. When creating the event bus, enable **Schema discovery**.
3. Create an EventBridge pipe by following the steps in the Creating an Amazon EventBridge pipe section of the EventBridge user guide.

a. When configuring the source, in the **Source** field select *DynamoDB* and in the **DynamoDB Streams** field select the name of the source table stream.

b. When configuring the target, in the **Target service** field select *EventBridge event bus* and in the **Event bus as target** field select the event bus created in step 2.

4. Write an example item to the source DynamoDB table to trigger an event. This will allow EventBridge to infer schema from the example item. This schema can be used to create rules for routing events. For example, if you are implementing a design pattern that involves overloading attributes, you may want to trigger different rules depending on the value of your sort key. Details on how to write an item to DynamoDB can be found in the Working with items and attributes section of the DynamoDB developer guide.

5. Create an example Python Lambda function to be used as a target by following the steps in the Building Lambda functions with Python section of the Lambda developer guide. When creating your function, you can use the below example code to demonstrate the integration. When invoked, it will print the `NewImage` and `OldImage` received with the event which can be viewed in CloudWatch Logs.

```
import json

def lambda_handler(event, context):
    dynamodb = event.get('detail', {}).get('dynamodb', {})
    new_image = dynamodb.get('NewImage')
    old_image = dynamodb.get('OldImage')

    if new_image:
        print("NewImage:", json.dumps(new_image, indent=2))
    if old_image:
        print("OldImage:", json.dumps(old_image, indent=2))

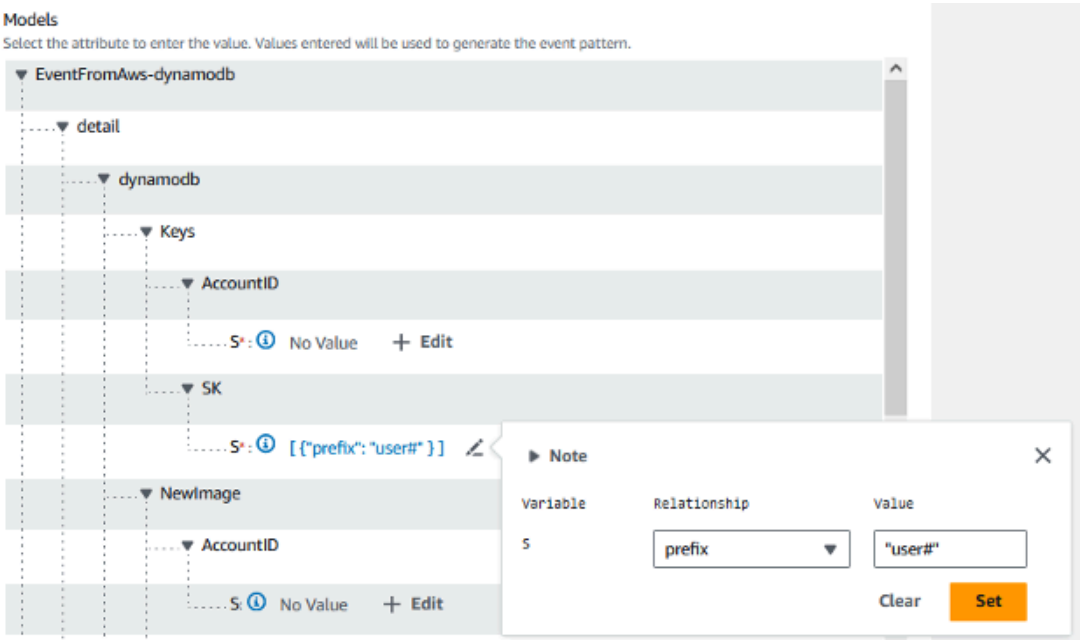
    return {'statusCode': 200, 'body': json.dumps(event)}
```

6. Create an EventBridge rule that will route events to your new Lambda function by following the steps in the Create a rule section that reacts to events EventBridge user guide.

a. When defining the rule detail, select the name of the event bus you created in step 2 as the **Event bus**.

b. When building the event pattern, follow the guide for **Existing schema**. Here, you can select the *discovered-schemas* registry and the discovered schema for your event. This allows you to configure an event pattern specific to your use case that only routes messages that match

specific attributes. For example, if you wanted to match only on DynamoDB items where the SK begins with "`user#`", you'd use a configuration like this.



c. Choose **Generate event pattern in JSON** after you've finished designing a pattern against your schema. If you instead want to match all events that appear on DynamoDB Streams, use the following JSON for the event pattern.

```
{
  "source": ["aws.dynamodb"]
}
```

d. When selecting targets, follow the guide for AWS service. In the Select a target field, choose "Lambda function". In the Function field, select the Lambda function you created in step 5.

7. You can now stop schema discovery on your event bus by following the steps in the Starting or stopping schema discovery on event buses section of the EventBridge user guide.
8. Write a second example item to the source DynamoDB table to trigger an event. Validate that the event was successfully processed at each step.

   a. View the CloudWatch metric **PutEventsApproximateSuccessCount** for your event bus by following the Monitoring Amazon EventBridge section of the EventBridge user guide.

   b. View function logs for your Lambda function by following the Monitoring and troubleshooting Lambda functions section of the Lambda developer guide. If your Lambda function uses the example code provided, you should see the `NewImage` and `OldImage` from DynamoDB Streams printed in the CloudWatch Logs log group.

c. View the **Error count and success rate (%)** metric for your Lambda function by following the Monitoring and troubleshooting Lambda functions section of the Lambda developer guide.

Next steps

This example provides a basic integration with a single Lambda function as a target. For a better understanding of more complex configurations, such as creating multiple rules, creating multiple targets, integrating with other services, and enriching events see the complete EventBridge user guide: Getting started with EventBridge.

> **Note**
>
> Be aware of any EventBridge quotas that might be relevant to your application. While DynamoDB Streams capacity scales with your table, EventBridge quotas are separate. Common quotas to be aware of in a large application would be **Invocations throttle limit in transactions per second** and **PutEvents throttle limit in transactions per second**. These quotas specify the number of invocations that can be sent to targets and the number of events that can be put into the bus per second.

Integrating DynamoDB with Amazon Managed Streaming for Apache Kafka

Amazon Managed Streaming for Apache Kafka (Amazon MSK) makes it easy to ingest and process streaming data in real time with a fully managed, highly available Apache Kafka service.

Apache Kafka is a distributed data store optimized for ingesting and processing streaming data in real-time. Kafka can process streams of records, effectively store streams of records in the order in which records were generated, and publish and subscribe to streams of records.

Because of these features, Apache Kafka is often used to build real-time streaming data pipelines. A *data pipeline* reliably processes and moves data from one system to another and can be an important part of adopting a purpose-built database strategy by facilitating the use of multiple databases which each support different use cases.

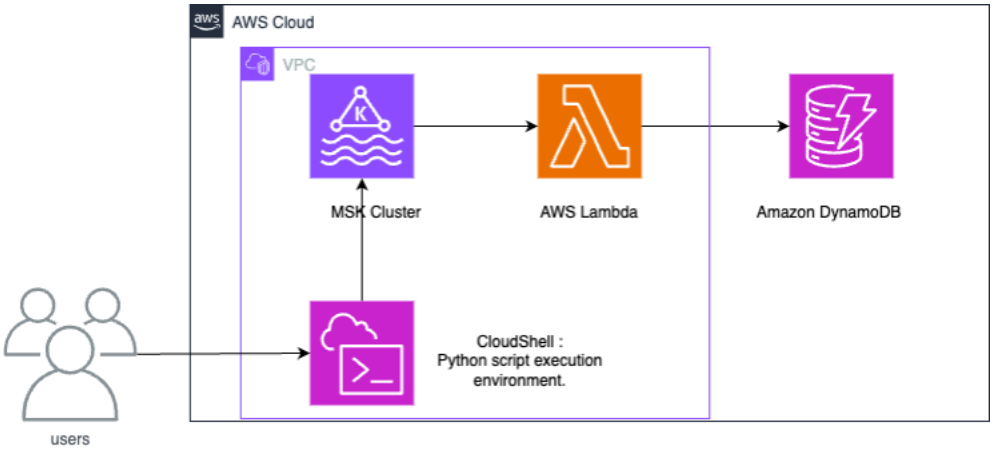
Amazon DynamoDB is common target in these data pipelines to support applications that use key-value or document data models and desire limitless scalability with consistent single-digit millisecond performance.

Topics

- How it works
- Set up an integration between Amazon MSK and DynamoDB
- Next steps

How it works

An Integration between Amazon MSK and DynamoDB uses a Lambda function to consume records from Amazon MSK and write them to DynamoDB.



Lambda internally polls for new messages from Amazon MSK and then synchronously invokes the target Lambda function. The Lambda function's event payload contains batches of messages from Amazon MSK. For the integration between Amazon MSK and DynamoDB, the Lambda function writes these messages to DynamoDB.

Set up an integration between Amazon MSK and DynamoDB

> **Note**
>
> You can download the resources used in this example at the following GitHub repository.

The steps below show how to set up a sample integration between Amazon MSK and Amazon DynamoDB. The example represents data generated by Internet of Things (IoT) devices and ingested into Amazon MSK. As data is ingested into Amazon MSK, it can be integrated with analytics services or third-party tools compatible with Apache Kafka, enabling various analytics use cases. Integrating DynamoDB as well provides key value lookup of individual device records.

This example will demonstrate how a Python script writes IoT sensor data to Amazon MSK. Then, a Lambda function writes items with the partition key "`deviceid`" to DynamoDB.

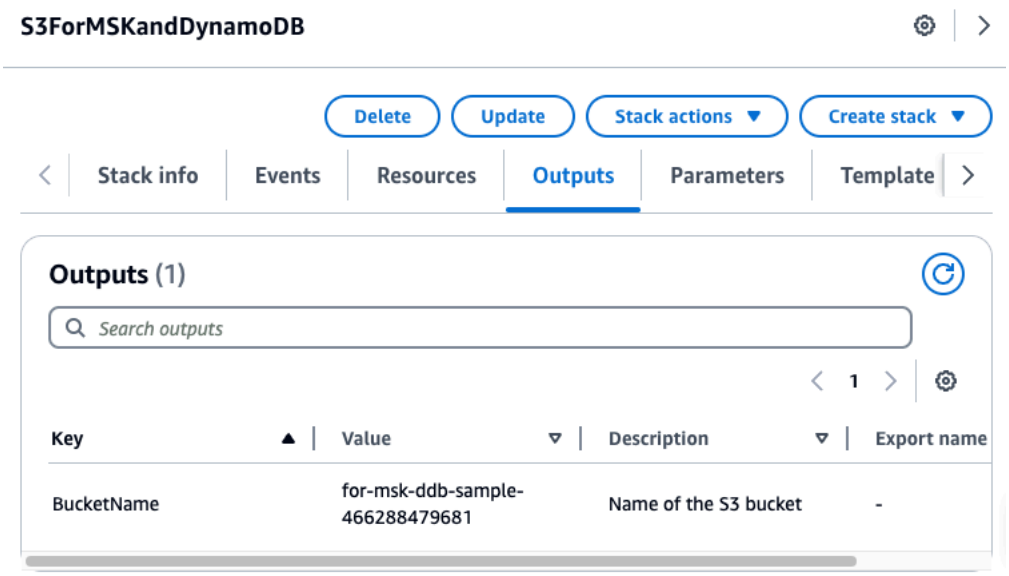
The provided CloudFormation template will create the following resources: An Amazon S3 bucket, an Amazon VPC, a Amazon MSK cluster, and an AWS CloudShell for testing data operations.

To generate test data, create an Amazon MSK topic and then create a DynamoDB table. You can use Session Manager from the management console to log into the CloudShell's operating system and run Python scripts.

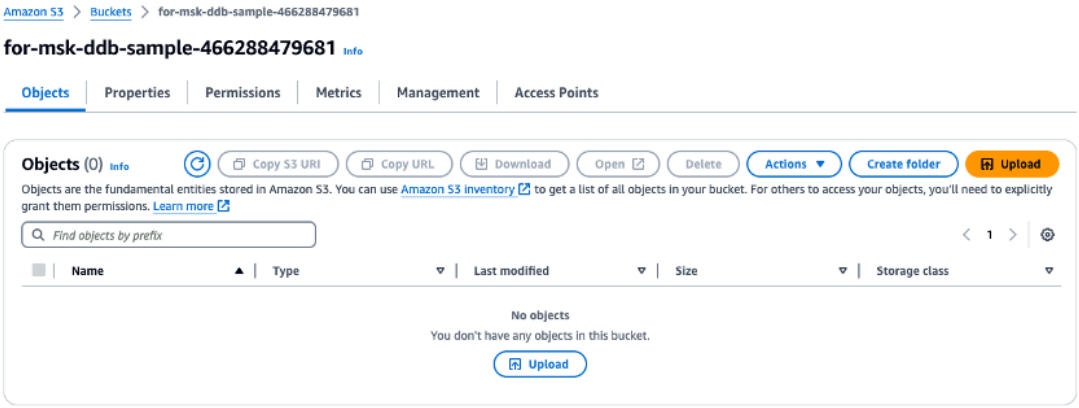
After running the CloudFormation template, you can finish building this architecture by performing the following operations.

1. Run the CloudFormation template `S3bucket.yaml` to create an S3 bucket. For any subsequent scripts or operations, please run them in the same Region. Enter `ForMSKTestS3` as the CloudFormation stack name.

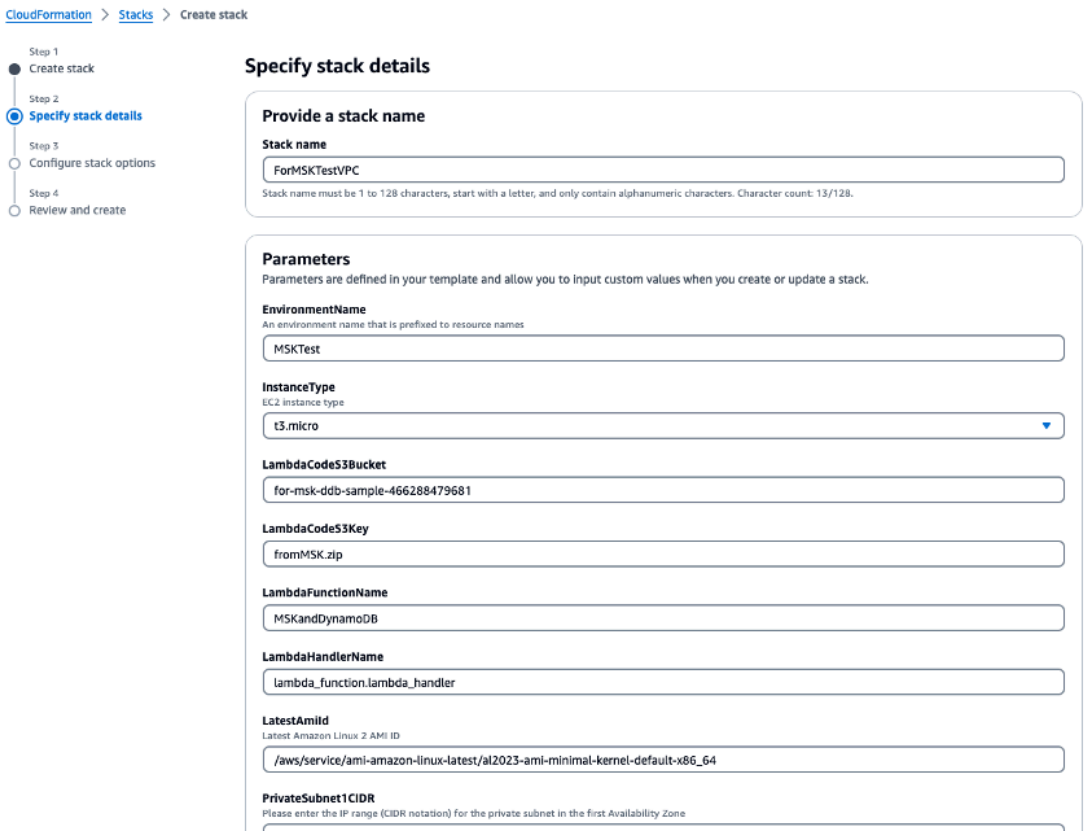
   After this is completed, note down the S3 bucket name output under *Outputs*. You will need the name in Step 3.



2. Upload the downloaded ZIP file `fromMSK.zip` to the S3 bucket you just created.

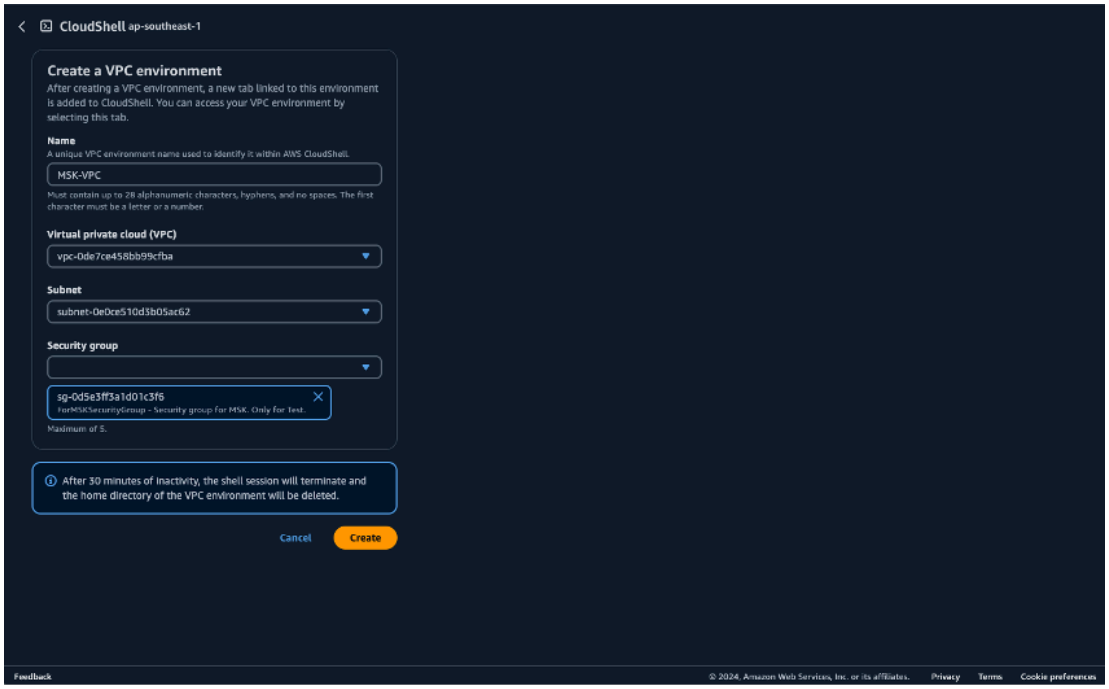


3. Run the CloudFormation template `VPC.yaml` to create a VPC, Amazon MSK cluster, and Lambda function. On the parameter input screen, enter the S3 bucket name you created in Step 1 where it asks for the S3 bucket. Set the CloudFormation stack name to `ForMSKTestVPC`.



4. Prepare the environment for running Python scripts in CloudShell. You can use CloudShell on the AWS Management Console. For more information on using CloudShell, see Getting started with AWS CloudShell. After starting CloudShell, create a CloudShell that belongs to the VPC you have just created in order to connect to the Amazon MSK Cluster. Create the CloudShell in a private subnet. Fill in the following fields:

    1. **Name** - can be set to any name. An example is **MSK-VPC**
    2. **VPC** - select **MSKTest**
    3. **Subnet** - select **MSKTest Private Subnet (AZ1)**
    4. **SecurityGroup** - select **ForMSKSecurityGroup**



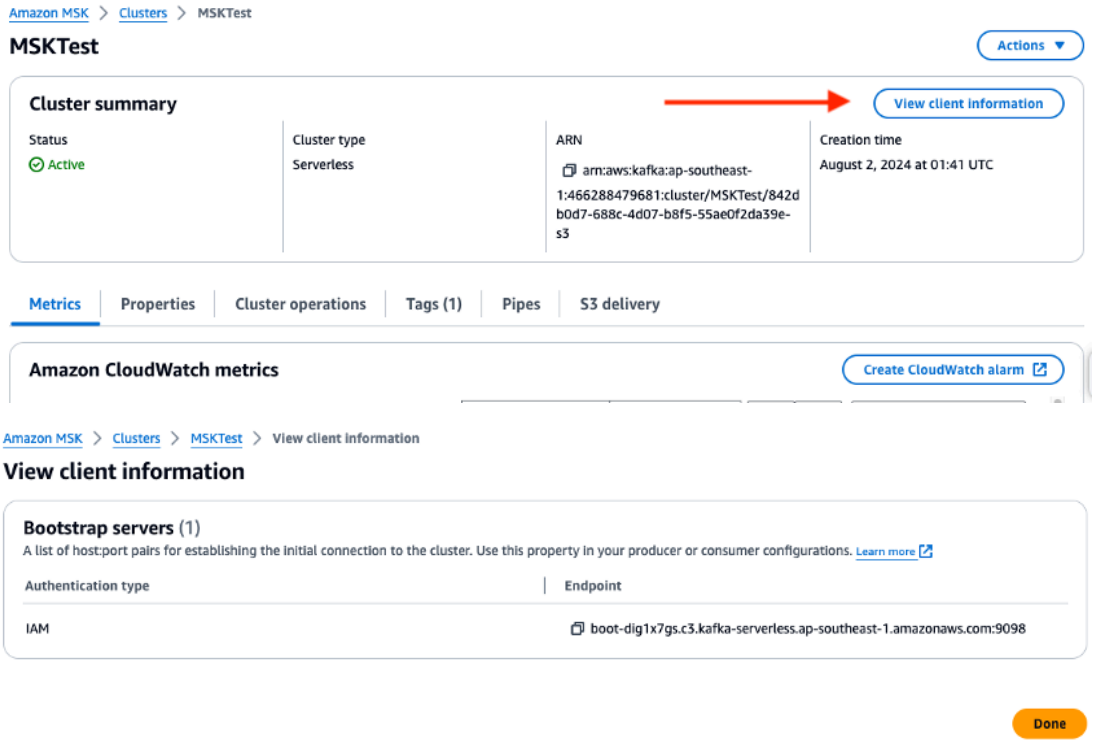
After the CloudShell belonging to the Private Subnet has started, run the following command:

```
pip install boto3 kafka-python aws-msk-iam-sasl-signer-python
```

5. Download Python scripts from the S3 bucket.

```
aws s3 cp s3://[YOUR-BUCKET-NAME]/pythonScripts.zip ./
unzip pythonScripts.zip
```

6. Check the management console and set the environment variables for the broker URL and Region value in the Python scripts. Check the Amazon MSK cluster broker endpoint in the management console.



7. Set the environment variables on the CloudShell. If you are using the US West (Oregon):

```
export AWS_REGION="us-west-2"
export MSK_BROKER="boot-YOURMSKCLUSTER.c3.kafka-serverless.ap-
southeast-1.amazonaws.com:9098"
```

8. Run the following Python scripts.

   Create an Amazon MSK topic:

```
python ./createTopic.py
```

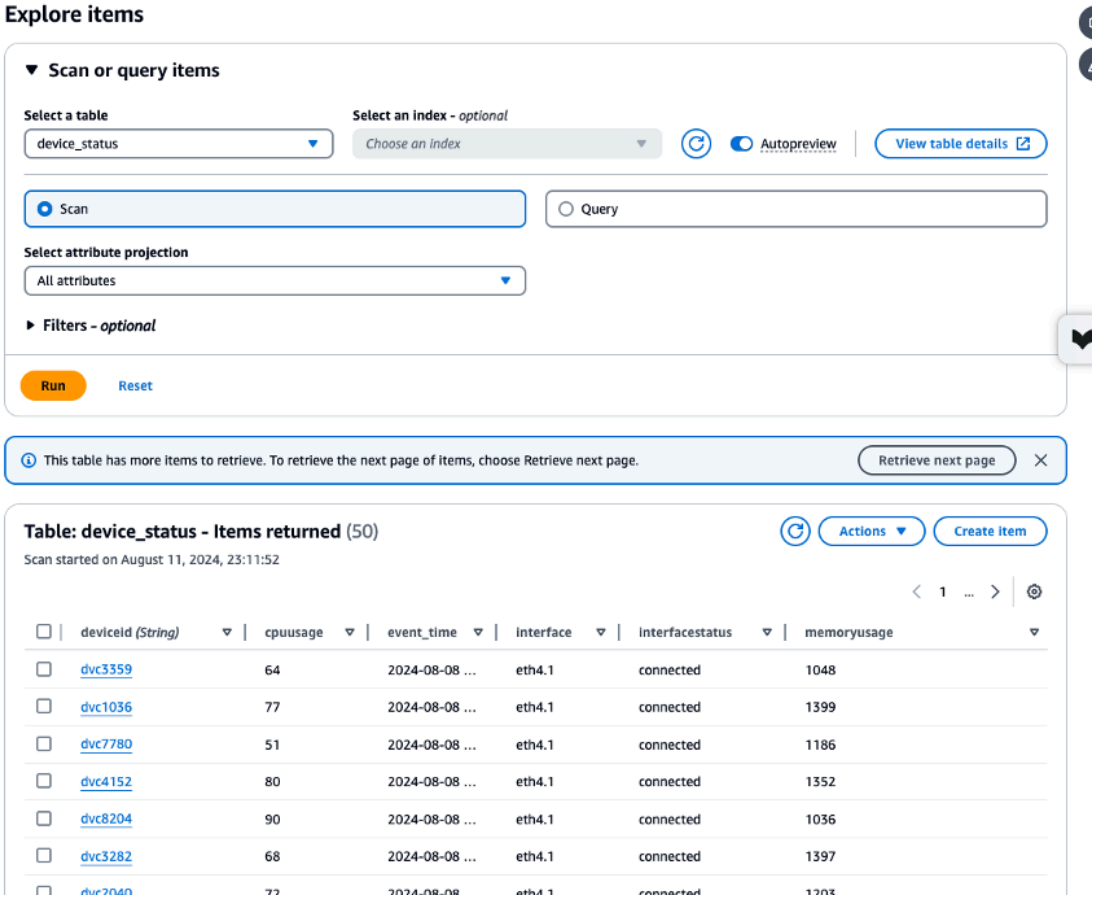
   Create a DynamoDB table:

```
python ./createTable.py
```

Write test data to the Amazon MSK topic:

```
python ./kafkaDataGen.py
```

9. Check the CloudWatch metrics for the created Amazon MSK, Lambda, and DynamoDB resources, and verify the data stored in the `device_status` table using the DynamoDB Data Explorer to make sure all processes ran correctly. If each process is run without error, you can check that the test data written from CloudShell to Amazon MSK is also written to DynamoDB.



10. When you're done with this example, delete the resources created in this tutorial. Delete the two CloudFormation stacks: `ForMSKTestS3` and `ForMSKTestVPC`. If the stack deletion completes successfully, all resources will be deleted.

Next steps

> **Note**
>
> If you created resources while following along with this example, please remember to delete them to avoid any unexpected charges.

The Integration identified an architecture that links Amazon MSK and DynamoDB to enable stream data to support OLTP workloads. From here, more complex searches can be realized by linking DynamoDB with OpenSearch Service. Consider integrating with EventBridge for more complex event-driven needs, and extensions such as Amazon Managed Service for Apache Flink for higher throughput and lower latency requirements.

Best practices for integrating with DynamoDB

When integrating DynamoDB with other services, you should always follow the best practices for using each individual service. However, there are some best practices specific to integration that you should consider.

Topics

- Creating a snapshot in DynamoDB
- Capturing data change in DynamoDB

Creating a snapshot in DynamoDB

- Generally, we recommend using export to Amazon S3 to create snapshots for initial replication. It is both cost effective, and won't compete with your application's traffic for throughput. You can also consider a backup and restore to a new table followed by a scan operation. This will avoid competing for throughput with your application, but will generally be substantially less cost effective than an export.
- Always set a `StartTime` when doing an export. This makes it easy to determine where you'll start your change data capture (CDC) from.
- When using export to S3, set a lifecycle action on the S3 bucket. Typically, an expiration action set at 7 days is safe, but you should follow any guidelines that your company might have. Even

if you explicitly delete your items after ingestion, this action can help catch issues, which helps reduce unnecessary costs and prevents policy violations.

Capturing data change in DynamoDB

- If you need near real-time CDC, use DynamoDB Streams or Amazon Kinesis Data Streams (KDS). When you're deciding which one to use, generally consider which is easiest to use with the downstream service. If you need to provide in-order event processing at a partition-key level, or if you have items that are exceptionally large, use DynamoDB Streams.
- If you don't need near real-time CDC, you can use export to Amazon S3 with incremental exports to export only the changes that have happened between two points in time.

  If you used export to S3 for generating a snapshot, this can be especially helpful because you can use similar code to process incremental exports. Typically, export to S3 is slightly cheaper than the previous streaming options, but cost is typically not the main factor for which option to use.
- You can generally only have two simultaneous consumers of a DynamoDB stream. Consider this when planning your integration strategy.
- Don't use scans to detect changes. This might work on a small scale, but becomes impractical fairly quickly.

Using agentic AI with DynamoDB

Amazon DynamoDB is a serverless, fully managed, distributed NoSQL database with single-digit millisecond performance at any scale. DynamoDB is optimized for high-throughput workloads and you can extend its capabilities by integrating with generative AI models. Using generative AI models, you can work with data stored in DynamoDB tables in real-time and build applications that are contextually aware and highly personalized. You can also enhance the end user experience by fully leveraging your business, user, and application data to customize your generative AI solutions.

For more information about gen AI and the solutions AWS provides to build gen AI applications, see Transform your business with generative AI.

DynamoDB also provides native vector search through vector indexes, so you can store vector embeddings alongside your operational data and run similarity searches with the `SearchVectors` API, without a separate vector database. For more information, see Using vector indexes in DynamoDB.

- Vector search for RAG and agent memory
- AI framework connectors for DynamoDB
- Generative AI blogs for DynamoDB
- Leveraging DynamoDB Zero-ETL integration with OpenSearch Service

Generative AI use cases for DynamoDB

DynamoDB is widely used in AI powered conversational applications, such as chatbots and call centers built with a Foundation Model (FM). You can access FMs through Amazon Bedrock, Amazon SageMaker AI, or other model providers. Such applications commonly use DynamoDB to improve personalization and enhance the user experience across three data patterns: application data, business data, and user data. Some examples of these data patterns are as follows:

- Storage of application data, such as chat message history, through integrations with LangChain, LlamaIndex, or a custom code. This context enhances the user experience by allowing the model to *converse* back and forth with the user. For more DynamoDB integrations with agentic AI frameworks, see AI framework connectors for DynamoDB.

- Creation of a customized user experience by leveraging business data, such as inventory, pricing, and documentation.
- Application of user data, such as web history, past orders, and user preferences, to provide personalized answers.

For instance, an insurance company can build a chatbot using DynamoDB to provide their Retrieval-Augmented Generation (RAG) based gen AI model access to near real-time data. Examples of such data are real-time mortgage rates, product pricing, compliant/standard contract copy, user web history, and user preferences. Combining DynamoDB with RAG adds in-depth and updated information about insurance products and the user data. This enriches the prompts and answers to provide end users with an accurate, personalized, and near real-time experience.

Similarly, financial services industry customers use DynamoDB, Amazon Bedrock knowledge bases, and Amazon Bedrock agents to build RAG-based gen AI applications. These applications can use open-source earnings reports and call transcripts. They can also use user-specific portfolio and transaction history to generate an on-demand summary of portfolio including an outlook for the future.

Vector search for RAG and agent memory

Generative AI applications retrieve context by meaning: a RAG application finds the documents most relevant to a prompt, and an AI agent recalls memories similar to the current conversation. Vector indexes bring this capability natively to DynamoDB. You store vector embeddings as attributes on your table items, and the `SearchVectors` API returns the items most similar to a query vector, ranked by similarity score. The data an application writes is the data it searches, so there is no separate vector database to provision and no replication pipeline to manage.

You can also define a partition key in a vector index's search schema. Each similarity search is then scoped to a single partition key value, such as a tenant ID, user ID, or agent session ID. This makes vector indexes a natural fit for multi-tenant RAG and per-user agent memory.

To get started with vector indexes, see the following topics:

- Using vector indexes in DynamoDB
- Tutorial: Your first vector search
- Creating and searching vector indexes
- Best practices for vector indexes

AI framework connectors for DynamoDB

AI agents need durable storage for everything they must remember: conversation state that survives a restart, chat history that spans sessions, and long-term memories they can recall in later conversations. Open source connectors, maintained by AWS and by the framework communities, integrate DynamoDB with popular AI agent frameworks so that state lives in a serverless database with single-digit millisecond latency, in your own AWS account.

The following table summarizes the available connectors and what each one stores.

Framework	Package	What it stores in DynamoDB	Languages
Strands Agents	`strands-dynamodb-storage`	Session state, long-term memories, transcripts, and oversized tool results, through the SDK's unified storage contract	Python, TypeScript
LangChain	`langchain-community` , `langchain-aws`	Chat message history, and documents with embeddings for vector similarity search	Python, JavaScript
LangGraph	`langgraph-checkpoint-aws`	Agent checkpoints (short-term conversation state) and long-term, cross-thread memories	Python

Using DynamoDB as a storage backend for Strands Agents

Strands Agents is an open source SDK that takes a model-driven approach to building AI agents in a few lines of code, with first-class support for Amazon Bedrock and other model providers. Among its building blocks is a unified storage interface: a byte-oriented contract (`write`, `read`, `delete`, `list`) that every stateful subsystem in the SDK speaks. The Session Manager persists conversation snapshots through it, the Memory Manager stores long-term memories through it, and the context offloader and transcripts use the same operations.

The strands-dynamodb-storage package implements that contract on a single DynamoDB table, for both Python and TypeScript. The SDK's `/`-separated storage keys map directly onto the DynamoDB key model: a key's first two segments become the partition key and the remainder becomes the sort key, so point operations are single-item calls and listing a prefix is a native partition `Query`, never a table scan.

Key features

One table for all agent state

A single `DynamoDBStorage` instance backs session persistence, long-term memory, transcripts, and context offloading, each namespaced under its own key prefix.

Semantic memory search

With a vector index on the table, memories can be written with embeddings and recalled by meaning through the `SearchVectors` API. See Semantic long-term memory with vector indexes.

Amazon S3 offload for large values

Offload is opt-in: pass a bucket name on the constructor, and values above the 400 KB DynamoDB item size limit are transparently offloaded to Amazon Simple Storage Service, with a small pointer item remaining in the table.

Optional compression and Time to Live

Optional gzip compression keeps compressible values inline at lower cost. Optional Time to Live stamps a DynamoDB-native expiry attribute, and reads and listings filter items whose expiry has already passed.

Multi-tenant prefixes

A constructor-bound key prefix pins every operation inside its own key space, so two tenants sharing a table resolve the same logical key to physically distinct partitions.

Prerequisites

- An AWS account with permissions to create DynamoDB tables (and optionally Amazon S3 buckets, if you configure large-value offload)
- Python 3.10 or later with `strands-agents` 1.48.0 or later, or Node.js 20 or later with `@strands-agents/sdk` 1.10.0 or later
- AWS credentials configured (see the AWS documentation for credential setup options)
- For semantic memory: access to an embeddings model such as Amazon Titan Text Embeddings V2 in Amazon Bedrock, and a table created with a vector index (see Using vector indexes in DynamoDB)

Installation

Install the package from PyPI:

```
pip install strands-dynamodb-storage "strands-agents>=1.48.0"
```

Or from npm for TypeScript (the TypeScript package is a feature-parity mirror):

```
npm install strands-dynamodb-storage
```

Create the table

The package holds no `CreateTable` permission and never creates infrastructure: you create the table in advance, with your own tagging, backup, and encryption settings applied. A table with a string partition key `pk` and a string sort key `sk` is the only requirement:

```
aws dynamodb create-table \
  --table-name agent-storage \
  --attribute-definitions AttributeName=pk,AttributeType=S
 AttributeName=sk,AttributeType=S \
  --key-schema AttributeName=pk,KeyType=HASH AttributeName=sk,KeyType=RANGE \
  --billing-mode PAY_PER_REQUEST
```

If you plan to use semantic memory, declare the vector index in this same command: an index's name, dimensions, and distance function cannot be changed after creation, so size the dimensions to your embedding model. The package README shows the full call that declares the index.

Persist agent sessions

Hand the storage to your agent's session manager. The SDK namespaces the keys, snapshots the conversation on every invocation, and restores it when the same session returns:

```
from strands import Agent
from strands.session import SnapshotSessionManager
from strands_dynamodb_storage import DynamoDBStorage

storage = DynamoDBStorage("agent-storage", region_name="us-east-1")
session = SnapshotSessionManager(session_id="user-42", storage=storage)

agent = Agent(session_manager=session)
agent("Where did we leave off?")
```

You can also set storage once on the `Agent` itself. Every subsystem that accepts a storage then inherits it, each namespaced under its own key prefix, so one table carries the whole agent's state:

```
from strands.vended_plugins.context_offloader import ContextOffloader

agent = Agent(
    storage=storage,
    session_manager=SnapshotSessionManager(),  # persists under session/
    plugins=[ContextOffloader()],              # offloads oversized tool results under
 offloader/
)
```

The byte contract is also available directly. The contract is async: inside an agent the SDK drives it for you, and in a plain script you wrap the calls in `asyncio.run`:

```
import asyncio

async def main():
    await storage.write("session/user-42/notes", b"prefers aisle seats")
    keys = await storage.list("session/user-42/")

asyncio.run(main())
```

Semantic long-term memory with vector indexes

Session persistence solves half of the memory problem: your agent survives a restart and resumes the conversation. The harder half is recalling something a user told the agent weeks ago, in a new conversation that shares no keys with the old one, and that requires searching memories by meaning rather than by key. DynamoDB vector indexes bring nearest-neighbor search to the same table that holds your agent's state (see Using vector indexes in DynamoDB).

The following examples embed text with Amazon Titan Text Embeddings V2 through Amazon Bedrock. The model returns 1,024-dimension vectors by default, so the index for these examples is created with 1,024 dimensions. The following code defines the `embed()` function that the remaining examples use:

```
import json

import boto3

bedrock = boto3.client("bedrock-runtime", region_name="us-east-1")

def embed(text):
    response = bedrock.invoke_model(
        modelId="amazon.titan-embed-text-v2:0",
        body=json.dumps({"inputText": text, "dimensions": 1024}),
    )
    return json.loads(response["body"].read())["embedding"]
```

Writing a memory attaches an embedding and optional metadata alongside the bytes. The following code constructs the store with a per-tenant prefix, so the key `memories/m1` lands in the physical partition `user/u1`:

```
from strands_dynamodb_storage import DynamoDBStorage, SearchQuery

storage = DynamoDBStorage("agent-storage", region_name="us-east-1", prefix="user/u1")

await storage.write(
    "memories/m1",
    b"prefers window seats on long flights",
    vector=embed("prefers window seats on long flights"),
    metadata={"kind": "preference"},
)
```

Recalling by meaning is one call, scoped to the same partition:

```
results = await storage.search(SearchQuery(
    vector=embed("what are this user's seating preferences?"),
    top_k=5,
    pk="user/u1",  # the physical partition: the full key's first two segments
    filter={"kind": "preference"},
))
```

Notice the `pk` argument. The vector index is partitioned the same way the table is, and every search is scoped to one partition, so a tenant's search never ranges over another tenant's memories, and the work each search performs tracks the size of that tenant's memory rather than the whole table. Keep in mind that the partition value is supplied by the caller, so this is query scoping rather than an authorization boundary: a principal holding `dynamodb:SearchVectors` on the table can search any partition, and tenant access control belongs in IAM and your application layer.

Results return most similar first. The raw score's direction follows the index's distance function: lower is nearer for cosine and Euclidean distance, and higher is more similar for dot product.

Wire memory into an agent

In a real agent you want retrieved memories to reach the model automatically, and the SDK's Memory Manager handles that: it retrieves relevant entries before each model call and folds them into the model input, and it registers a `search_memory` tool the model can call on demand. The Memory Manager accepts any object implementing the SDK's `MemoryStore` protocol. The package does not ship one, so you define a small class in your own application that embeds on write, embeds on search, and returns `MemoryEntry` values:

```
import uuid
```

```
from strands.memory import MemoryEntry
from strands_dynamodb_storage import DynamoDBStorage, SearchQuery

class DynamoDBMemoryStore:
    def __init__(self, storage, partition, embed):
        self.storage = storage
        self.partition = partition
        self.embed = embed  # the embed() function defined earlier
        self.name = "dynamodb"
        self.description = "Long-term memories in DynamoDB, searched by meaning"
        self.max_search_results = 3
        self.writable = True
        self.extraction = None

    async def add(self, content, metadata=None):
        await self.storage.write(
            f"memories/{uuid.uuid4().hex[:8]}",
            content.encode(),
            vector=self.embed(content),
            metadata=metadata,
        )

    async def search(self, query, options=None):
        results = await self.storage.search(SearchQuery(
            vector=self.embed(query),
            top_k=self.max_search_results,
            pk=self.partition,
            include_values=True,
        ))
        return [
            MemoryEntry(content=r.data.decode(), metadata=r.metadata)
            for r in results
            if r.data is not None
        ]
```

The following code seeds three memories and wires the store into the agent, so retrieved memories reach the model with no orchestration code on your side:

```
import asyncio

from strands import Agent
```

```
from strands.memory import MemoryManager

storage = DynamoDBStorage("agent-storage", region_name="us-east-1", prefix="user/u1")
store = DynamoDBMemoryStore(storage, partition="user/u1", embed=embed)

async def seed():
    await store.add("Prefers window seats on long flights")
    await store.add("Planning a trip to Tokyo in December")
    await store.add("Allergic to peanuts")

asyncio.run(seed())

memory = MemoryManager(stores=[store], add_tool_config=True)
agent = Agent(memory_manager=memory)
agent("Book me a flight seat for my December trip. Which seat should I pick?")
```

Running this against a live table, the agent calls its `search_memory` tool, matches the Tokyo trip and the window-seat preference from DynamoDB, and recommends a window seat for the flight. Passing `add_tool_config=True` also registers an `add_memory` tool, so the model can store new facts through the same table it recalls from.

Required IAM permissions

At runtime the package issues four DynamoDB operations, plus `SearchVectors` when you use semantic search, and Amazon S3 operations only when you configure offload, so the least-privilege IAM policy is short. Replace *111122223333* with your AWS account ID and update the Region to match your environment:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:PutItem",
        "dynamodb:GetItem",
        "dynamodb:DeleteItem",
        "dynamodb:Query"
      ],
      "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/agent-storage"
```

```
    }
  ]
}
```

The package README carries the complete policy, including the additional statements for semantic search, Amazon S3 offload, and embedding model invocation.

Considerations

- A vector index's name, dimensions, and distance function are immutable after creation, and a newly created index backfills before it is searchable. A table supports 5 vector indexes by default, and you can request up to 20, so adopting a different configuration later means adding an index, not rebuilding the table.
- Vector indexes are eventually consistent, the same model as a global secondary index. A memory written moments ago may take a short time to become searchable.
- Time to Live expiry filtering applies to read and list operations. Because Time to Live deletion is asynchronous, a search can briefly return items whose expiry has passed but which DynamoDB has not yet physically removed.
- Listing requires a prefix that covers at least a full scope and identifier. Broad listings such as an empty prefix are rejected; the package never falls back to a table scan.
- If you enable Time to Live on offloaded values, add an Amazon S3 lifecycle rule: DynamoDB removes the expired pointer item, and the lifecycle rule is what reclaims the Amazon S3 object.

Using DynamoDB with LangChain

LangChain is a framework for building applications with large language models (LLMs). Two LangChain integrations use DynamoDB: the `DynamoDBChatMessageHistory` class stores conversation history so a model can converse back and forth with a user across sessions, and the

`DynamoDBVectorStore` class implements the LangChain vector store interface on DynamoDB vector indexes for similarity search.

Chat message history

The `DynamoDBChatMessageHistory` class, in the `langchain-community` package for Python and the `@langchain/community` package for JavaScript, persists chat messages in a DynamoDB table. The class expects an existing table whose partition key is a string attribute named `SessionId` (configurable through `primary_key_name`). Create the table with the AWS CLI:

```
aws dynamodb create-table \
  --table-name SessionTable \
  --attribute-definitions AttributeName=SessionId,AttributeType=S \
  --key-schema AttributeName=SessionId,KeyType=HASH \
  --billing-mode PAY_PER_REQUEST
```

Install the packages, then read and write history keyed by a session ID:

```
pip install langchain-community boto3
```

```
from langchain_community.chat_message_histories import DynamoDBChatMessageHistory

history = DynamoDBChatMessageHistory(
    table_name="SessionTable",
    session_id="user-42",
)

history.add_user_message("Hello!")
history.add_ai_message("How can I help you today?")

print(history.messages)
```

Each chat session's messages are stored under its `session_id`, so a returning user picks up the conversation where they left off. The constructor also supports composite keys for isolating history by application details such as a user ID (`key`), Time to Live-based expiry of old sessions (`ttl`), and a cap on stored messages (`history_size`). For the full API, see the Python reference and the JavaScript reference.

Vector store backed by vector indexes

The `DynamoDBVectorStore` class, in the `langchain-aws` package, implements the LangChain vector store interface using DynamoDB vector indexes (see Using vector indexes in DynamoDB). Documents are stored as regular DynamoDB items and searched through the table's vector index with the `SearchVectors` API, so LangChain retrievers and RAG chains run similarity searches directly against the table that holds your data.

Install the package:

```
pip install langchain-aws boto3
```

Provide a table name and an embedding function. The table and vector index are created on first write if they don't exist:

```
from langchain_aws.embeddings import BedrockEmbeddings
from langchain_aws.vectorstores.dynamodb import DynamoDBVectorStore

vector_store = DynamoDBVectorStore.from_texts(
    ["hello", "developer", "wife"],
    embedding=BedrockEmbeddings(model_id="amazon.titan-embed-text-v2:0"),
    table_name="my-documents",
)

docs = vector_store.similarity_search("greeting", k=2)
```

To scope searches, pass `partition_attribute` when you construct the store. The vector index is then created with a search schema partition key on that document metadata field, and each search examines only one value of it, such as a collection, category, or tenant, rather than the whole corpus. Every search then supplies the value through `filter={partition_attribute: value}` or a store-level `default_partition_value`. The partition key is part of the index schema and cannot be changed after the index is created.

Keep the following in mind:

- Like a global secondary index, the vector index is eventually consistent: a search issued immediately after `add_texts` may not include the just-written documents until the index catches up.
- `SearchVectors` returns at most the top 100 matches per query, so the store's `k` parameter is capped at 100.

- The index's dimensions, distance function, and search schema are fixed at creation. The store validates them against an existing index rather than proceeding with a mismatch.

For the full API, see DynamoDBVectorStore in the langchain-aws repository.

Using DynamoDB as a checkpoint store for LangGraph agents

LangGraph is a framework for building stateful, multi-actor AI applications with Large Language Models (LLMs). LangGraph agents require persistent storage to maintain conversation state, enable human-in-the-loop workflows, support fault tolerance, and provide time-travel debugging capabilities. DynamoDB's serverless architecture, single-digit millisecond latency, and automatic scaling make it an ideal checkpoint store for production LangGraph deployments on AWS.

The `langgraph-checkpoint-aws` package provides a `DynamoDBSaver` class that implements the LangGraph checkpoint interface, enabling you to persist agent state in DynamoDB with optional Amazon Simple Storage Service offloading for large checkpoints.

The same package also provides a `DynamoDBStore` class that implements the LangGraph store interface for long-term, cross-thread agent memory, with semantic search backed by DynamoDB vector indexes. For more information, see Semantic long-term memory for LangGraph agents. This topic covers the checkpoint saver.

Key features

State persistence

Automatically saves agent state after each step, enabling agents to resume from interruptions and recover from failures.

Time to Live-based cleanup

Automatically expire old checkpoints using DynamoDB Time to Live to manage storage costs.

Compression

Optionally compress checkpoint data with gzip to reduce storage costs and improve throughput.

Amazon S3 offloading

Automatically offload large checkpoints (greater than 350 KB) to Amazon Simple Storage Service to work within DynamoDB item size limits.

Sync and async support

Both synchronous and asynchronous APIs for flexibility in different application architectures.

Prerequisites

- Python 3.10 or later
- An AWS account with permissions to create DynamoDB tables (and optionally Amazon S3 buckets)
- AWS credentials configured (see the AWS documentation for credential setup options)

Installation

Install the checkpoint package from PyPI:

```
pip install langgraph-checkpoint-aws
```

Basic usage

The following example demonstrates how to configure DynamoDB as a checkpoint store for a LangGraph agent:

```
from langgraph.graph import StateGraph
from langgraph_checkpoint_aws import DynamoDBSaver
from typing import TypedDict

# Define your state schema
```

```
class State(TypedDict):
    input: str
    result: str

# Initialize the DynamoDB checkpoint saver
checkpointer = DynamoDBSaver(
    table_name="langgraph-checkpoints",
    region_name="us-east-1"
)

# Build your LangGraph workflow
builder = StateGraph(State)
builder.add_node("process", lambda state: {"result": "processed"})
builder.set_entry_point("process")
builder.set_finish_point("process")

# Compile the graph with the DynamoDB checkpointer
graph = builder.compile(checkpointer=checkpointer)

# Invoke the graph with a thread ID to enable state persistence
config = {"configurable": {"thread_id": "session-123"}}
result = graph.invoke({"input": "data"}, config)
```

The `thread_id` in the configuration acts as the partition key in DynamoDB, allowing you to maintain separate conversation threads and retrieve historical states for any thread.

Production configuration

For production deployments, you can enable Time to Live, compression, and Amazon S3 offloading. You can also use the `endpoint_url` parameter to point to a local DynamoDB instance for testing:

```
import boto3
from botocore.config import Config
from langgraph_checkpoint_aws import DynamoDBSaver

# Production configuration
session = boto3.Session(
    profile_name="production",
    region_name="us-east-1"
)

checkpointer = DynamoDBSaver(
    table_name="langgraph-checkpoints",
```

```
    session=session,
    ttl_seconds=86400 * 7,           # Expire checkpoints after 7 days
    enable_checkpoint_compression=True,  # Enable gzip compression
    boto_config=Config(
        retries={"mode": "adaptive", "max_attempts": 6},
        max_pool_connections=50
    ),
    s3_offload_config={
        "bucket_name": "my-checkpoint-bucket"
    }
)

# Local testing with DynamoDB Local
local_checkpointer = DynamoDBSaver(
    table_name="langgraph-checkpoints",
    region_name="us-east-1",
    endpoint_url="http://localhost:8000"
)
```

DynamoDB table configuration

The checkpoint saver requires a DynamoDB table with a composite primary key. You can create the table using the following AWS CloudFormation template:

```
AWSTemplateFormatVersion: '2010-09-09'
Description: 'DynamoDB table for LangGraph checkpoint storage'

Parameters:
  TableName:
    Type: String
    Default: langgraph-checkpoints

Resources:
  CheckpointTable:
    Type: AWS::DynamoDB::Table
    DeletionPolicy: Retain
    UpdateReplacePolicy: Retain
    Properties:
      TableName: !Ref TableName
      BillingMode: PAY_PER_REQUEST
      AttributeDefinitions:
        - AttributeName: PK
          AttributeType: S
```

```
        - AttributeName: SK
          AttributeType: S
      KeySchema:
        - AttributeName: PK
          KeyType: HASH
        - AttributeName: SK
          KeyType: RANGE
      TimeToLiveSpecification:
        AttributeName: ttl
        Enabled: true
      PointInTimeRecoverySpecification:
        PointInTimeRecoveryEnabled: true
      SSESpecification:
        SSEEnabled: true
```

Deploy the template with the AWS CLI:

```
aws cloudformation deploy \
  --template-file template.yaml \
  --stack-name langgraph-checkpoint \
  --parameter-overrides TableName=langgraph-checkpoints
```

Required IAM permissions

The following IAM policy provides the minimum permissions required for the DynamoDB checkpoint saver. Replace *111122223333* with your AWS account ID and update the Region to match your environment.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:PutItem",
        "dynamodb:Query",
        "dynamodb:BatchGetItem",
        "dynamodb:BatchWriteItem"
      ],
      "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/langgraph-checkpoints"
    }
```

```
  ]
}
```

If you enable Amazon S3 offloading, add the following statement to the policy:

```
{
  "Effect": "Allow",
  "Action": [
    "s3:PutObject",
    "s3:GetObject",
    "s3:DeleteObject",
    "s3:PutObjectTagging"
  ],
  "Resource": "arn:aws:s3:::my-checkpoint-bucket/*"
},
{
  "Effect": "Allow",
  "Action": [
    "s3:GetBucketLifecycleConfiguration",
    "s3:PutBucketLifecycleConfiguration"
  ],
  "Resource": "arn:aws:s3:::my-checkpoint-bucket"
}
```

Asynchronous usage

For asynchronous applications, use the async methods provided by the checkpoint saver:

```
import asyncio
from langgraph.graph import StateGraph
from langgraph_checkpoint_aws import DynamoDBSaver
from typing import TypedDict

class State(TypedDict):
    input: str
    result: str

async def main():
    checkpointer = DynamoDBSaver(
        table_name="langgraph-checkpoints",
        region_name="us-east-1"
    )
    builder = StateGraph(State)
```

```
    builder.add_node("process", lambda state: {"result": "processed"})
    builder.set_entry_point("process")
    builder.set_finish_point("process")
    graph = builder.compile(checkpointer=checkpointer)

    config = {"configurable": {"thread_id": "async-session-123"}}
    result = await graph.ainvoke({"input": "data"}, config)
    return result

asyncio.run(main())
```

Error handling

Common error scenarios:

- **Table not found**: Verify the `table_name` and `region_name` match your DynamoDB table.
- **Throttling**: If you see `ProvisionedThroughputExceededException`, consider switching to on-demand billing mode or increasing provisioned capacity.
- **Item size exceeded**: If checkpoints exceed 350 KB, enable Amazon S3 offloading (see Production configuration).
- **Credential errors**: Verify your AWS credentials are valid and have the required permissions.

Semantic long-term memory for LangGraph agents

LangGraph separates two kinds of agent state. Short-term state is the conversation thread itself, which a checkpointer persists so a thread can resume, replay, and recover (see Using DynamoDB as a checkpoint store for LangGraph agents). Long-term memory is what the agent knows across threads, and LangGraph models it as a store: a namespaced key-value surface the agent writes to deliberately and reads back later.

The `DynamoDBStore` class, in the langgraph-checkpoint-aws package, is the DynamoDB implementation of that store. It handles the key-value side with hierarchical namespaces, Time to Live for expiring stale memories, and basic filtering. With a vector index configured (see Using vector indexes in DynamoDB), its `search()` method performs semantic search: memories are embedded on write, indexed asynchronously, and recalled by meaning, ranked by similarity, from the same table that holds them. There is no separate vector database to provision and no pipeline copying data into it.

Prerequisites

- An AWS account with permission to create DynamoDB tables and invoke Amazon Bedrock models
- Access to an embeddings model in Amazon Bedrock in your Region. These examples use Amazon Titan Text Embeddings V2
- Python 3.10 or later, with `langgraph-checkpoint-aws` 1.2.2 or later and `boto3` 1.43.64 or later (earlier `boto3` versions have no `SearchVectors` operation)

Install the libraries using pip:

```
pip install langgraph langgraph-checkpoint-aws langchain-aws
```

Set up the store

Configure the store with an `index` block and call `setup()`:

```
from langchain_aws import BedrockEmbeddings
from langgraph_checkpoint_aws import DynamoDBStore

store = DynamoDBStore(
    table_name="support-agent-memory",
    region_name="us-east-1",
    index={
        "embed": BedrockEmbeddings(model_id="amazon.titan-embed-text-v2:0"),
        "dims": 1024,
        "fields": ["text"],
        "distance_function": "COSINE",
    },
)
```

```
store.setup()
```

Four settings in the `index` block are worth understanding:

- `embed` takes any LangChain embeddings object, or a plain callable that maps a list of strings to a list of vectors.
- `dims` must match your model's output size. Titan Text Embeddings V2 returns 1,024 dimensions by default. If these disagree, the store raises a dimension mismatch error naming both numbers on the first write, rather than writing vectors the index can't use.
- `fields` selects which parts of the value get embedded. Here only the `text` field is embedded. The default, `["$"]`, serializes the whole value to JSON and embeds that, which is convenient but also embeds your bookkeeping attributes.
- `distance_function` defaults to `COSINE`, and also accepts `EUCLIDEAN` and `DOT_PRODUCT`.

`setup()` creates the table if it's absent, attaches the vector index, and enables Time to Live if you configured it. On an existing table, it adds only what's missing, so existing `DynamoDBStore` deployments can adopt semantic search without recreating the table or migrating items. Keep in mind that `setup()` doesn't return until the index reports `ACTIVE` and is no longer backfilling: an index that reports `ACTIVE` while still backfilling rejects `SearchVectors` calls. On a new empty table the wait is short. Retrofitting onto a table with existing items takes as long as the backfill takes.

Write memories

Writing is an ordinary `put()`. The embedding happens for you:

```
namespace = ("memories", "acme-corp", "user-8812")

store.put(namespace, "mem-1", {
    "text": "Account runs a proxy that closes idle sockets after 60 seconds",
    "source": "ticket-4471",
})
store.put(namespace, "mem-2", {
    "text": "Customer prefers email, asked not to be called by phone",
    "source": "ticket-4471",
})
store.put(namespace, "mem-3", {
    "text": "Uses a custom build of the SDK pinned to version 2.14",
    "source": "ticket-4502",
```

```
})
```

Recall by meaning

The customer opens a new conversation and says their connection keeps dropping after about a minute:

```
results = store.search(
    namespace,
    query="connection drops after a minute of inactivity",
    limit=3,
)

for item in results:
    print(round(item.score, 3), item.value["text"])
```

Output:

```
0.324 Account runs a proxy that closes idle sockets after 60 seconds
0.039 Customer prefers email, asked not to be called by phone
0.031 Uses a custom build of the SDK pinned to version 2.14
```

The relevant memory ranks first, and no key in the query matched anything. `SearchItem.score` follows the LangGraph convention where higher is more relevant. DynamoDB returns a distance, where lower is closer, so the store converts: for `COSINE` the score is `1 - distance`, for `EUCLIDEAN` it is `1 / (1 + distance)`, and `DOT_PRODUCT` scores pass through unchanged. If you gate on an absolute score to decide whether a memory is relevant enough to inject into a prompt, calibrate that threshold against your own data and your chosen distance function.

Scope memory with the search schema

When `DynamoDBStore` creates the vector index, it declares the table's partition key as a `HASH` element in the index search schema. Because that element exists, every search must supply a condition for it, and the store supplies the namespace: the namespace tuple is joined to form the partition key value, so every semantic search is pinned to exactly one namespace. Three consequences follow:

- **Isolation is structural, not a filter you remember to write.** A search cannot reach a memory in a different namespace, so a store serving many tenants has no query shape that returns another tenant's memories. This is query scoping rather than authorization: a principal with

`dynamodb:SearchVectors` permission on the table can search any namespace value directly, so deciding which namespaces a caller may read still belongs to IAM and your application's authorization layer.

- **Recall cost tracks one user's memory, not your whole table.** The search work is bounded by how much that one namespace holds, not by how many memories your whole product holds, which keeps both latency and vector search cost small and stable as you grow.
- **Semantic search is exact-namespace, not prefix.** A search reaches exactly the namespace you pass and nothing beneath it. Searching `("memories", "acme-corp")` does not reach `("memories", "acme-corp", "user-8812")`, because those are different partition key values. Your namespace is your recall scope, so choose it to match the scope you want a single search to see.

The following table summarizes how to choose a namespace shape.

Namespace shape	One `search()` reaches	Choose it when
`("memories", user_id)`	That user's memories	Single-tenant product with per-user recall
`("memories", tenant_id, user_id)`	That user, at that tenant	Multi-tenant, the common case
`("memories", tenant_id, user_id, agent_name)`	One agent's notes on that user	Multiple specialized agents that shouldn't read each other's notes
`("account_facts", tenant_id)`	Tenant-wide knowledge	Facts that apply to every user at an account

Avoid putting every memory in one namespace and filtering on metadata: filters are applied after DynamoDB has already selected the nearest matches across the entire namespace, and a single search returns at most the top 100 matches, so once one busy tenant fills the top 100 for a common query, a quieter tenant's search returns fewer results than requested even though their memories are present. Prefer namespace scoping over filters for anything that determines correctness. Going finer than your recall boundary is a legitimate design too: an agent that needs both user-specific and account-wide context searches both namespaces and merges the results.

Considerations

- The index is eventually consistent, the same model as a global secondary index. A `search()` issued immediately after a `put()` may not include the new memory yet. For an agent that writes a memory and then recalls it within the same turn, read it back by key instead.
- A single search returns at most the top 100 matches. A request whose `limit` plus `offset` exceeds it is rejected with a clear error rather than silently returning nothing beyond the cap.
- If you use Time to Live to expire stale memories and enable refresh on read, a memory the agent actually recalls has its expiry pushed out, so the memories in active use are not the ones quietly disappearing.
- Vector search failures raise so your application can react. A throttle, a permissions problem, and a genuinely empty result would look identical if the store returned an empty list on failure.
- Vector operations bill in their own units, metered separately from base table read and write request units, and both scale with the number of dimensions. A smaller embedding dimension is cheaper on every write and every search, so use the smallest dimension that holds your recall quality.
- Memories written with no text in the configured `fields` are stored without an embedding and won't appear in semantic results. The store logs a warning when this happens.

Generative AI blogs for DynamoDB

The following articles offer detailed use cases, best practices, and step-by-step guides to help you leverage DynamoDB's capabilities in building advanced AI-powered applications.

- Amazon DynamoDB data models for generative AI chatbots
- Build a scalable, context-aware chatbot with Amazon DynamoDB, Amazon Bedrock, and LangChain
- Build durable AI agents with LangGraph and Amazon DynamoDB

Leveraging DynamoDB Zero-ETL integration with OpenSearch Service

You can use Amazon Bedrock with DynamoDB to provide serverless access to foundational models (FMs), such as Amazon Titan and other third-party models. For vector search on data in DynamoDB, you can use native vector indexes (see Using vector indexes in DynamoDB). If you also want full-text search, analytics, or hybrid search capabilities alongside vector search, you can leverage the Zero-ETL integration with Amazon OpenSearch Service when building generative AI applications. The Generative AI with DynamoDB zero-ETL to OpenSearch integration and Amazon Bedrock workshop provides you hands-on experience in setting up DynamoDB Zero-ETL integration with OpenSearch. This workshop does the following tasks:

- Creates a pipeline from your DynamoDB table to OpenSearch.
- Creates an Amazon Bedrock Connector in OpenSearch.
- Queries Amazon Bedrock leveraging OpenSearch as a vector store.
- Uses the Claude FM in Amazon Bedrock to create a written response in plain English explaining the search results returned by OpenSearch.

This workshop enables you to integrate DynamoDB with OpenSearch to build generative AI applications. It also demonstrates the flexible querying capability across database engines to help you integrate DynamoDB and OpenSearch for traditional use cases. This workshop is one of the seven modules in the Amazon DynamoDB Immersion Day. You can run this workshop in any AWS account.

You can also refer to the following blog post about how to set up a Zero-ETL integration between DynamoDB and OpenSearch Service. This blog post also describes how to set up model connectors in OpenSearch Service to automatically generate embeddings using Amazon Bedrock for incoming data. Vector search for Amazon DynamoDB with zero ETL for Amazon OpenSearch Service.

Quotas and constraints for Amazon DynamoDB

This topic describes current quotas, formerly referred to as limits, within Amazon DynamoDB. This topic also describes how you can perform the quota management tasks, for example, viewing your current quotas and requesting a quota increase.

Topics

- Performing quota management tasks in DynamoDB
- Requesting a quota increase in DynamoDB
- Quotas in Amazon DynamoDB
- Constraints in Amazon DynamoDB

Performing quota management tasks in DynamoDB

Amazon DynamoDB has several service components, such as tables, streams, indexes, and more. When you create your AWS account, there are default *quotas* (formerly referred to as limits) set on these components. Unless otherwise noted, each quota is Region-specific. You can request increases for some of the quotas. After a quota for a resource has been reached, additional requests to create that resource fail with an exception.

Accessing DynamoDB quotas

You can work with DynamoDB Service Quotas in the following ways:

- AWS Management Console

  The Service Quotas console is a browser-based interface that you can use to view and manage your Service Quotas. You can access Service Quotas from any AWS Management Console page by choosing it on the top navigation bar, or by searching for Service Quotas in the AWS Management Console.
- AWS Command Line Interface tools

  When using AWS Command Line Interface tools, you can issue commands at your system's command line to perform Service Quotas tasks. The command line tools are useful if you want to build scripts that perform AWS tasks.
- AWS SDKs

You can use the AWS SDKs for various programming languages and platforms (for example, Java, Python, Ruby, .NET, iOS and Android, and others) to perform Service Quotas tasks.

If an adjustable quota isn't available in the Service Quotas console, use the AWS Support Center Console to create a Service Quotas increase case.

Viewing current quotas in the console

To view your current DynamoDB quotas using the Service Quotas console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/home/services/dynamodb/quotas/
2. From the navigation bar, at the top of the screen, select a Region.
3. The console displays details about the DynamoDB **Quota name**, **Applied account-level quota value**, **AWS default quota value**, **Utilization**, and the **Adjustability** of the quota at the account-level or resource-level.

   If the applied quota value or utilization is not available, the console displays **Not available**. You can request your applied quota value through the Support Center Console.
4. Choose a specific **Quota name** to view the **Details** page, which displays that quota's **Description**, **Quota code**, **Quota ARN**, **Utilization**, **Applied account-level quota value**, **Adjustability**, and **AWS default quota value**.

   If applicable, the **Details** page also displays any **Monitoring** options, **Alarms**,**request history**, and any of the quota's **Tags**.

Viewing current quotas using the AWS CLI

To view the default values for DynamoDB quotas:

- Call the `ListDefaultServiceQuotas` operation with the DynamoDB service code (dynamodb) to retrieve default values for Amazon DynamoDB Service quotas.

```
$ aws service-quotas list-aws-default-service-quotas \
        --service-code dynamodb

 {
```

```
    "Quotas": [
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1::dynamodb/L-F7858A77",
            "QuotaCode": "L-F7858A77",
            "QuotaName": "Global Secondary Indexes per table",
            "Value": 20.0,
            "Unit": "None",
            "Adjustable": true,
            "GlobalQuota": false
        },
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1::dynamodb/L-AB614373",
            "QuotaCode": "L-AB614373",
            "QuotaName": "Table-level write throughput limit",
            "Value": 40000.0,
            "Unit": "None",
            "Adjustable": true,
            "GlobalQuota": false
        }......
    ]
}
```

To view the applied quota values:

- Call the `ListServiceQuotas` operation with the DynamoDB service code (dynamodb) to retrieve all applied quota values either at the account-level, resource-level, or all levels by passing `ACCOUNT`, `RESOURCE`, or `ALL` respectively as the value for the parameter `QuotaAppliedAtLevel`. The following CLI example retrieves quota values applied at the account-level.

```
$ aws service-quotas list-service-quotas \
        --service-code dynamodb \
        --quota-applied-at-level ACCOUNT

{
    "Quotas": [
```

```
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1:303935678045:dynamodb/L-
F7858A77",
            "QuotaCode": "L-F7858A77",
            "QuotaName": "Global Secondary Indexes per table",
            "Value": 20.0,
{
    "Quotas": [
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1:303935678045:dynamodb/L
-F7858A77",
            "QuotaCode": "L-F7858A77",
            "QuotaName": "Global Secondary Indexes per table",
            "Value": 20.0,
            "Unit": "None",
            "Adjustable": true,
            "GlobalQuota": false,
            "QuotaAppliedAtLevel": "ACCOUNT"
        }.....

        }
    ]
}
```

Requesting a quota increase in DynamoDB

You can request a quota increase for each Region using the Service Quotas console, AWS CLI or a support case. If an adjustable quota isn't available in the Service Quotas console, use the AWS Support Center Console to create a service quota increase case.

Support could approve, deny, or partially approve your quota increase requests. Increases aren't granted immediately, and can take a few days to take effect.

To request an increase using the Service Quotas console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/home/services/dynamodb/quotas/

2. From the navigation bar, at the top of the screen, select a Region.
3. Filter the list by resource name. For example, enter **On-Demand** to locate the quotas for On-Demand Instances.
4. If the quota is adjustable, choose the quota and then choose **Request quota increase**.
5. For **Change quota value**, enter the new quota value.
6. Choose **Request**.
7. To view any pending or recently resolved requests in the console, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number with Support. Choose the case number to open the ticket for your request.

For more information, including how to use the AWS CLI or SDKs to request a quota increase, see Requesting a quota increase in the *Service Quotas User Guide*.

Quotas in Amazon DynamoDB

This section describes current quotas, formerly referred to as limits, within Amazon DynamoDB. Each quota applies on a per-Region basis unless otherwise specified.

> **Note**
>
> All size measurements in DynamoDB use binary-based units. DynamoDB denotes 1 KB = 1024 bytes, 1 MB = 1024 KB, 1 GB = 1024 MB, 1 TB = 1024 GB.

Read/write throughput

Throughput default quotas

AWS places some default quotas on the throughput that your account can provision and consume within a Region.

The account-level read throughput and account-level write throughput quotas apply at the account level. These account-level quotas apply to the sum of the provisioned throughput capacity for all your account's tables and global secondary indexes in a given Region. All the account's available throughput can be provisioned for a single table or across multiple tables. These quotas only apply to tables using the provisioned capacity mode.

The table-level read throughput and table-level write throughput quotas apply differently to tables that use the provisioned capacity mode, and tables that use the on-demand capacity mode.

For provisioned capacity mode tables and GSIs, the quota is the maximum amount of read and write capacity units that can be provisioned for any table or any of its GSIs in the Region. The total of any individual table and all its GSIs must also remain below the account-level read and write throughput quota. This is in addition to the requirement that the total of all provisioned tables and their GSIs must remain below the account-level read and write throughput quota.

For on-demand capacity mode tables and GSIs, the table-level quota is the maximum read and write capacity units that are available for any table, or any individual GSI within that table. No account-level read and write throughput quotas are applied to tables in on-demand mode.

Following are the throughput quotas that apply on your account, by default.

> **Note**
>
> All capacity unit and request unit quotas are measured per second. For example, a quota of 40,000 read capacity units means 40,000 reads per second.

> **Note**
>
> You can request any number of read capacity units (RCU) or write capacity units (WCU) for your DynamoDB tables through a service quota increase. The values listed in the following table represent the initial default quotas. These are not maximum limits for your tables.

Throughput quota name	On-Demand	Provisioned	Adjustable
Per table	40,000 read request units and 40,000 write request units	40,000 read capacity units and 40,000 write capacity units	Yes
Per account	Not applicable	80,000 read capacity units and 80,000 write capacity units	Yes
Minimum throughput for any table or global secondary index	Not applicable	1 read capacity unit and 1 write capacity unit	Yes

Increasing or decreasing throughput (for provisioned tables)

Increasing provisioned throughput

You can increase `ReadCapacityUnits` or `WriteCapacityUnits` as often as necessary, using the AWS Management Console or the `UpdateTable` operation. In a single call, you can increase the provisioned throughput for a table, for any global secondary indexes on that table, or for any combination of these. The new settings do not take effect until the `UpdateTable` operation is complete.

You can't exceed your per-account quotas when you add provisioned capacity, and DynamoDB doesn't allow you to increase provisioned capacity very rapidly. Aside from these restrictions, you can increase the provisioned capacity for your tables as high as you need. For more information about per-account quotas, see the preceding section, Throughput default quotas.

Decreasing provisioned throughput

For every table and global secondary index in an `UpdateTable` operation, you can decrease `ReadCapacityUnits` or `WriteCapacityUnits` (or both). The new settings don't take effect until the `UpdateTable` operation is complete.

There is a default quota on the number of provisioned capacity decreases you can perform on your DynamoDB table per day. A day is defined according to Universal Time Coordinated (UTC). You start each day with 4 available decreases. Each hour, 1 additional decrease becomes available, up to the maximum of 4 available at any time. Over a full 24-hour day, this allows you to decrease up to 27 times (4 in the first hour, plus 1 for each of the remaining 23 hours).

> **Important**
>
> Table and global secondary index decrease limits are decoupled, so any global secondary indexes for a particular table have their own decrease limits. However, if a single request decreases the throughput for a table and a global secondary index, it is rejected if either exceeds the current limits. Requests are not partially processed.

Example

In the first 4 hours of a day, a table with a global secondary index can be modified as follows:

- Decrease the table's `WriteCapacityUnits` or `ReadCapacityUnits` (or both) four times.
- Decrease the `WriteCapacityUnits` or `ReadCapacityUnits` (or both) of the global secondary index four times.

At the end of that same day, the table and the global secondary index throughput can potentially be decreased a total of 27 times each.

Reserved Capacity

AWS places a default quota on the amount of active reserved capacity that your account can purchase. The quota limit is a combination of reserved capacity for write capacity units (WCUs) and read capacity units (RCUs).

Reserved capacity quota	Active reserved capacity	Adjustable
Per account	1,000,000 provisioned capacity units (WCUs _ RCUs)	Yes

If you attempt to purchase more than 1,000,000 provisioned capacity units in a single purchase, you will receive an error for this service quota limit. If you have active reserved capacity and attempt to purchase additional reserved capacity that would result in more than 1,000,000 active provisioned capacity units, you will receive an error for this service quota limit.

Tables

Table size

There is no practical limit on a table's size. Tables are unconstrained in terms of the number of items or the number of bytes.

Maximum number of tables per account per region

For any AWS account, there is an initial quota of 2,500 tables per AWS Region.

If you need more than 2,500 tables for a single account, please reach out to your AWS account team to explore an increase up to a maximum of 10,000 tables. For more than 10,000, the recommended best practice is to setup multiple accounts, each of which can serve up to 10,000 tables.

Global tables

The following default quotas apply when using global tables.

Default global table quotas	On-Demand	Provisioned
Number of MRSC global tables (See the section called "Consistency modes")	400 total MRSC global tables in any capacity mode	400 total MRSC global tables in any capacity mode

Default global table quotas	On-Demand	Provisioned
Throughput per table configured for multi-Region eventual consistency (MREC)	40,000 read request units and 40,000 write request units	40,000 read capacity units and 40,000 write capacity units
Throughput per table configured for multi-Region strong consistency (MRSC)	40,000 read request units and 40,000 write request units	40,000 read capacity units and 40,000 write capacity units
Backfilled data for new replicas per account, per Region, per day	10 TB	10 TB

Note

There may be instances where you will need to request a quota limit increase through AWS Support. If any of the following apply to you, please see https://aws.amazon.com/support:

- Global table throughput quotas must be equal to or greater than per table throughput quotas for replica creation to succeed. There are separate global table throughput quotas for MREC and MRSC global tables.
- If you are adding a replica or replicas to one destination Region within a 24-hour period with a combined total greater than 10TB, you must request a service quota increase for your add replica data backfill quota.
- The table-level write throughput limit must be the same in every Region that has a replica. If you raise the table-level write throughput limit above the default in one Region, request a matching quota increase in every other replica Region before you add a replica. Otherwise, replica creation may fail with an error similar to the following:
  - Cannot create a replica of table 'example_table' in region 'example_region_A' because its exceeds your current account limit in region 'example_region_B'.

  If you receive this error, make sure your table-level write throughput limits match across all Regions where you are adding a replica. You can adjust these limits yourself through the Service Quotas console. For the table-level write throughput quota, see the section called “Read/write throughput”. If all Regions match and you still receive the error,

contact AWS Support at https://aws.amazon.com/support, because additional allow-listing might be required.

Secondary indexes

You can define up to 5 local secondary indexes per table.

There is a default quota of 20 global secondary indexes per table.

Vector indexes

The following quotas apply to vector indexes.

Quota	Default	Adjustable
Vector indexes per table	5	Yes, up to 20 (contact AWS Support)
Maximum dimensions per vector index	4,096	No
Maximum TopK per `SearchVectors` request	100	No
Maximum partition keys (HASH) per vector index	1	No
Vector search rate per partition key	1 GBps	Yes (contact AWS Support)
Vector index write rate per partition key	10 MBps	Yes (contact AWS Support)
Number of inline filters per vector index	18	No
Maximum base table size for vector index creation without allowlisting	600 GB	Yes (contact AWS Support)

Quota	Default	Adjustable
Concurrent vector index creations or deletions per table	1	No

You can request an increase to a maximum of 20 vector indexes per table. Vector indexes count toward the per-table quota for global secondary indexes, which has a default of 20. For example, with the default quota, a table with 15 vector indexes can have up to 5 other global secondary indexes.

Example. With a 768-dimensional embedding (such as Cohere Embed v3) and 1 KB of non-vector item data, each item is approximately 4 KB. At this item size, the per-partition-key throughput limits support approximately 250,000 vectors examined per second (1 GBps ÷ 4 KB) and 2,500 vector writes per second (10 MBps ÷ 4 KB). As the number of vectors in a partition grows, each search examines more data and you will approach the search limit sooner. Throughput scales linearly across partition key values. If your workload exceeds these limits, contact AWS Support.

Projected secondary index attributes

You can project up to 100 attributes combined for all of a table's local and global secondary indexes. This quota only applies to user-specified projected attributes.

For the `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the total count of attributes specified in `NonKeyAttributes` summed across all secondary indexes must not exceed 100. Projecting the same attribute name into two different indexes counts as two distinct attributes toward the quota.

This quota doesn't apply to secondary indexes with a `ProjectionType` of `KEYS_ONLY` or `ALL`.

DynamoDB Streams

Simultaneous readers of a shard in DynamoDB Streams

For single-Region tables that are not global tables, you can design for up to two simultaneous processes to read from the same DynamoDB Streams shard at the same time. Exceeding this limit can result in request throttling. For global tables, we recommend you limit the number of simultaneous readers to one to avoid request throttling.

Maximum write capacity for a table with DynamoDB Streams enabled

AWS places some default quotas on the write capacity for DynamoDB tables with DynamoDB Streams enabled. These default quotas are applicable only for tables in provisioned read/write capacity mode.

- Per table – 40,000 write capacity units

Import from Amazon S3

DynamoDB Import from Amazon S3 can support up to 50 concurrent import jobs with a total import source object size of 15TB at a time in us-east-1, us-west-2, and eu-west-1 regions. In all other regions, up to 50 concurrent import tasks with a total size of 1TB is supported. Each import job can take up to 50,000 Amazon S3 objects in all regions. For more information on import and validation, see import format quotas and validation.

Table export to Amazon S3

Full export: up to 300 concurrent export tasks, or up to a total of 100TB from all in-flight table exports, can be exported. Both of these limits are checked before an export is queued.

Incremental export: DynamoDB Incremental Export to Amazon S3 can support up to 300 concurrent export jobs or up to a total of 100TB from all in-flight table exports. The export period window limits are 15 minutes minimum and 24 hours maximum.

Backup and restore

DynamoDB supports up to 50 concurrent restores totaling 50 TB through DynamoDB on-demand or continuous backups. AWS Backup supports up to 50 concurrent restores totaling 25 TB.

Contributor Insights

When you enable Customer Insights on your DynamoDB table, you're still subject to Contributor Insights rules limits. For more information, see CloudWatch service quotas.

Constraints in Amazon DynamoDB

This section describes current constraints, formerly referred to as limits, within Amazon DynamoDB.

> **Note**
>
> All size measurements in DynamoDB use binary-based units. DynamoDB denotes 1 KB = 1024 bytes, 1 MB = 1024 KB, 1 GB = 1024 MB, 1 TB = 1024 GB.

Topics

- Read/write capacity mode
- Secondary indexes
- Partition keys and sort keys
- Naming rules
- Data types
- Items
- Attributes
- Expression parameters
- DynamoDB transactions
- DynamoDB Streams
- DynamoDB Accelerator (DAX)
- API-specific constraints
- DynamoDB encryption at rest

Read/write capacity mode

You can switch tables from provisioned capacity mode to on-demand mode up to four times in a 24-hour rolling window. You can switch tables from on-demand mode to provisioned capacity mode at any time.

For more information about switching between read and write capacity modes, see Considerations when switching capacity modes in DynamoDB.

Capacity unit sizes (for provisioned tables)

One read capacity unit = one strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.

One write capacity unit = one write per second, for items up to 1 KB in size.

Transactional read requests require two read capacity units to perform one read per second for items up to 4 KB.

Transactional write requests require two write capacity units to perform one write per second for items up to 1 KB.

Request unit sizes (for on-demand tables)

One read request unit = one strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.

One write request unit = one write per second, for items up to 1 KB in size.

Transactional read requests require two read request units to perform one read per second for items up to 4 KB.

Transactional write requests require two write request units to perform one write per second for items up to 1 KB.

Secondary indexes

Projected Secondary Index attributes per table

You can project a total of up to 100 attributes into all of a table's local and global secondary indexes. This only applies to user-specified projected attributes.

In a `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the total count of attributes specified in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 100. If you project the same attribute name into two different indexes, this counts as two distinct attributes when determining the total.

This limit does not apply for secondary indexes with a `ProjectionType` of `KEYS_ONLY` or `ALL`.

Partition keys and sort keys

Partition key length

The minimum length of a partition key value is 1 byte. The maximum length is 2048 bytes.

Partition key values

There is no practical limit on the number of distinct partition key values, for tables or for secondary indexes.

Sort key length

The minimum length of a sort key value is 1 byte. The maximum length is 1024 bytes.

Sort key values

In general, there is no practical limit on the number of distinct sort key values per partition key value.

The exception is for tables with secondary indexes. An item collection is the set of items which have the same value of partition key attribute. In a global secondary index the item collection is independent of the base table (and can have a different partition key attribute), but in a local secondary index the indexed view is colocated in the same partition as the item in the table and shares the same partition key attribute. As a result of this locality, when a table has one or more LSIs, the item collection cannot be distributed to multiple partitions.

For a table with one or more LSIs, item collections cannot exceed 10GB in size. This includes all base table items and all projected LSI views which have the same value of the partition key attribute. 10GB is the maximum size of a partition. For more detailed information, see Item collection size limit.

Naming rules

Table names and Secondary Index names

Names for tables and secondary indexes must be at least 3 characters long, but no greater than 255 characters long. The following are the allowed characters:

- `A-Z`
- `a-z`
- `0-9`
- _ (underscore)
- `-` (hyphen)
- `.` (dot)

Attribute names

In general, an attribute name must be at least one character long, but no greater than 64 KB long.

The following are the exceptions. These attribute names must be no greater than 255 characters long:

- Secondary index partition key names.
- Secondary index sort key names.
- The names of any user-specified projected attributes (applicable only to local secondary indexes). In a `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the names of the attributes in the `NonKeyAttributes` parameter are length-restricted. The `KEYS_ONLY` and `ALL` projection types are not affected.

These attribute names must be encoded using UTF-8, and the total size of each name (after encoding) cannot exceed 255 bytes.

Data types

String

The length of a String is constrained by the maximum item size of 400 KB.

Strings are Unicode with UTF-8 binary encoding. Because UTF-8 is a variable width encoding, DynamoDB determines the length of a String using its UTF-8 bytes.

Number

A Number can have up to 38 digits of precision, and can be positive, negative, or zero.

- Positive range: `1E-130` to `9.99999999999999999999999999999999999999E+125`
- Negative range: `-9.99999999999999999999999999999999999999E+125` to `-1E-130`

DynamoDB uses JSON strings to represent Number data in requests and replies. For more information, see DynamoDB low-level API.

If number precision is important, you should pass numbers to DynamoDB using strings that you convert from a number type.

Binary

The length of a Binary is constrained by the maximum item size of 400 KB.

Applications that work with Binary attributes must encode the data in base64 format before sending it to DynamoDB. Upon receipt of the data, DynamoDB decodes it into an unsigned byte array and uses that as the length of the attribute.

Items

Item size

The maximum item size in DynamoDB is 400 KB, which includes both attribute name binary length (UTF-8 length) and attribute value lengths (again binary length). The attribute name counts towards the size limit.

For example, consider an item with two attributes: one attribute named "shirt-color" with value "R" and another attribute named "shirt-size" with value "M". The total size of that item is 23 bytes.

Item size for tables with Local Secondary Indexes

For each local secondary index on a table, there is a 400 KB limit on the total of the following:

- The size of an item's data in the table.
- The size of corresponding entries (including key values and projected attributes) in all local secondary indexes.

Attributes

Attribute name-value pairs per item

The cumulative size of attributes per item must fit within the maximum DynamoDB item size (400 KB).

Number of values in list, map, or set

There is no limit on the number of values in a List, a Map, or a Set, as long as the item containing the values fits within the 400 KB item size limit.

Attribute values

Empty String and Binary attribute values are allowed, if the attribute is not used as a key attribute for a table or index. Empty String and Binary values are allowed inside Set, List, and Map types. An attribute value cannot be an an empty Set (String Set, Number Set, or Binary Set). However, empty Lists and Maps are allowed.

Nested attribute depth

DynamoDB supports nested attributes up to 32 levels deep.

Expression parameters

Expression parameters include `ProjectionExpression`, `ConditionExpression`, `UpdateExpression`, and `FilterExpression`.

Lengths

The maximum length of any expression string is 4 KB. For example, the size of the `ConditionExpression` `a=b` is 3 bytes.

The maximum length of any single expression attribute name or expression attribute value is 255 bytes. For example, `#name` is 5 bytes; `:val` is 4 bytes.

The maximum length of all substitution variables in an expression is 2 MB. This is the sum of the lengths of all `ExpressionAttributeNames` and `ExpressionAttributeValues`.

Operators and operands

The maximum number of operators or functions allowed in a single expression is 300. This limit applies to all expression types, including `ConditionExpression`, `FilterExpression`, and `UpdateExpression`.

Each of the following counts as one operator toward this limit:

- A comparator in a condition or filter expression, for example =, <>, <, <=, >, or >=.
- A logical keyword (`AND`, `OR`, `NOT`) or the `BETWEEN` or `IN` keyword.
- A function, for example `attribute_exists`, `begins_with`, `contains`, or `size`.
- An arithmetic operator (`+` or `-`) in an `UpdateExpression`.

In an `UpdateExpression`, the = in a `SET` action is assignment syntax and is *not* counted as an operator. In a condition or filter expression, the = comparator *is* counted. For example, the filter expression `#a = :val OR #b = :val` contains three operators (two = comparators and one `OR`), whereas the update expression `SET Price = Price + :val` contains one operator (the +).

> **Note**
>
> When an expression exceeds the 300-operator limit, DynamoDB returns a `ValidationException` with a message in the form `The expression contains too many operators; operator count: 301`. The reported count is always `301` and does not reflect the actual number of operators in the expression.

The maximum number of operands for the `IN` comparator is 100.

Reserved words

DynamoDB does not prevent you from using names that conflict with reserved words. (For a complete list, see Reserved words in DynamoDB.)

However, if you use a reserved word in an expression parameter, you must also specify `ExpressionAttributeNames`. For more information, see Expression attribute names (aliases) in DynamoDB.

DynamoDB transactions

DynamoDB transactional API operations have the following constraints:

- A transaction cannot contain more than 100 unique items.
- A transaction cannot contain more than 4 MB of data.
- No two actions in a transaction can work against the same item in the same table. For example, you cannot both `ConditionCheck` and `Update` the same item in one transaction.
- A transaction cannot operate on tables in more than one AWS account or Region.
- Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the AWS Region where the write is made originally. Transactions are not supported across Regions in global tables. For example, suppose that you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and you perform a `TransactWriteItems` operation in the US East (N. Virginia) Region. In this case, you might

observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

DynamoDB Streams

Simultaneous readers of a shard in DynamoDB Streams

For single-Region tables that are not global tables, you can design for up to two processes to read from the same DynamoDB Streams shard at the same time. Exceeding this limit can result in request throttling. For global tables, we recommend you limit the number of simultaneous readers to one to avoid request throttling.

DynamoDB Accelerator (DAX)

AWS Region availability

For a list of AWS Regions in which DAX is available, see DynamoDB Accelerator (DAX) in the *AWS General Reference*.

Nodes

A DAX cluster consists of exactly one primary node, and between zero and ten read replica nodes.

The total number of nodes (per AWS account) cannot exceed 50 in a single AWS Region.

Parameter groups

You can create up to 20 DAX parameter groups per Region.

Subnet groups

You can create up to 50 DAX subnet groups per Region.

Within a subnet group, you can define up to 20 subnets.

> **Important**
>
> A DAX cluster supports a maximum of 500 DynamoDB tables. After you go beyond 500 DynamoDB tables, your cluster might experience degradation in availability and performance.

API-specific constraints

CreateTable/UpdateTable/DeleteTable/PutResourcePolicy/DeleteResourcePolicy

In general, you can have up to 500 CreateTable, UpdateTable, DeleteTable, PutResourcePolicy, and DeleteResourcePolicy requests running simultaneously in any combination. As a result, the total number of tables in the CREATING, UPDATING, or DELETING state cannot exceed 500.

You can submit up to 2,500 requests per second of mutable (CreateTable, DeleteTable, UpdateTable, PutResourcePolicy, and DeleteResourcePolicy) control plane API requests across a group of tables. However, the PutResourcePolicy and DeleteResourcePolicy requests have lower individual limits. For more information, see the following quotas details for PutResourcePolicy and DeleteResourcePolicy.

CreateTable and PutResourcePolicy requests which include a resource-based policy will count as two additional requests for each KB of the policy. For example, a CreateTable or PutResourcePolicy request with a policy of size 5 KB will count as 11 requests. 1 for the CreateTable request and 10 for the resource-based policy (2 x 5 KB). Similarly, a policy of size 20 KB will count as 41 requests. 1 for the CreateTable request and and 40 for the resource-based policy (2 x 20 KB).

PutResourcePolicy

You can submit up to 25 PutResourcePolicy API requests per second across a group of tables. After a successful request for an individual table, no new PutResourcePolicy requests are supported for the following 15 seconds.

The maximum size supported for a resource-based policy document is 20 KB. DynamoDB counts whitespaces when calculating the size of a policy against this limit.

DeleteResourcePolicy

You can submit up to 50 DeleteResourcePolicy API requests per second across a group of tables. After a successful PutResourcePolicy request for an individual table, no DeleteResourcePolicy requests are supported for the following 15 seconds.

BatchGetItem

A single BatchGetItem operation can retrieve a maximum of 100 items. The total size of all the items retrieved cannot exceed 16 MB.

BatchWriteItem

A single `BatchWriteItem` operation can contain up to 25 `PutItem` or `DeleteItem` requests. The total size of all the items written cannot exceed 16 MB.

DescribeStream

You can call `DescribeStream` at a maximum rate of 10 times per second.

DescribeTableReplicaAutoScaling

`DescribeTableReplicaAutoScaling` method supports only 10 requests per second.

DescribeLimits

`DescribeLimits` should be called only periodically. You can expect throttling errors if you call it more than once in a minute.

DescribeContributorInsights/ListContributorInsights/UpdateContributorInsights

`DescribeContributorInsights`, `ListContributorInsights` and `UpdateContributorInsights` should be called only periodically. DynamoDB supports up to five requests per second for each of these APIs.

DescribeTable/ListTables/GetResourcePolicy

You can submit up to 2,500 requests per second of a combination of read-only (`DescribeTable`, `ListTables`, and `GetResourcePolicy`) control plane API requests. The `GetResourcePolicy` API has a lower individual limit of 100 requests per second.

DescribeTimeToLive

The `DescribeTimeToLive` operation is throttled at 10 read request units per second. If you exceed this limit, DynamoDB returns a `ThrottlingException` error.

`Query`

The result set from a `Query` is limited to 1 MB per call. You can use the `LastEvaluatedKey` from the query response to retrieve more results.

`Scan`

The result set from a `Scan` is limited to 1 MB per call. You can use the `LastEvaluatedKey` from the scan response to retrieve more results.

`UpdateKinesisStreamingDestination`

When performing `UpdateKinesisStreamingDestination` operations, you can set `ApproximateCreationDateTimePrecision` to a new value a maximum of 3 times in a 24 hour period.

`UpdateTableReplicaAutoScaling`

`UpdateTableReplicaAutoScaling` method supports only ten requests per second.

`UpdateTableTimeToLive`

The `UpdateTableTimeToLive` method supports only one request to enable or disable `Time to Live (TTL)` per specified table per hour. This change can take up to one hour to fully process. Any additional `UpdateTimeToLive` calls for the same table during this one hour duration result in a ValidationException.

DynamoDB encryption at rest

You can switch between an AWS owned key, an AWS managed key, and a customer managed key up to four times, anytime per 24-hour window, on a per table basis, starting from when the table was created. If there was no change in the past six hours, an additional change is allowed. This effectively brings the maximum number of changes in a day to eight (four changes in the first six hours, and one change for each of the subsequent six hour windows in a day).

You can switch encryption keys to use an AWS owned key as often as necessary, even if the above quota has been exhausted.

These are the quotas unless you request a higher amount. To request a service quota increase, see https://aws.amazon.com/support.

DynamoDB API reference

The Amazon DynamoDB API reference contains a complete list of operations supported by:

- DynamoDB
- DynamoDB Streams
- DynamoDB Accelerator (DAX)

Troubleshooting Amazon DynamoDB

The following topics provide troubleshooting advice for errors and issues that you could encounter when using Amazon DynamoDB. If you find an issue that isn't listed here, you can use the feedback button on this page to report it.

For more troubleshooting advice and answers to common support questions, visit the AWS Knowledge Center.

Topics

- Troubleshooting internal server errors in Amazon DynamoDB
- Troubleshooting latency issues in Amazon DynamoDB
- Troubleshooting throttling in Amazon DynamoDB

Troubleshooting internal server errors in Amazon DynamoDB

In DynamoDB, internal server errors (500 errors) indicate that the service is unable to serve the request. These errors can occur for various reasons, such as transient network issues in the fleet, infrastructure issues, storage node related issues, and more.

You might encounter some internal server errors during the lifecycle of your DynamoDB table. This is expected due to the distributed nature of the service and usually shouldn't be a cause for concern. DynamoDB automatically repairs and heals any transient issues with the service in real time, without requiring any intervention from you. However, if you observe a consistently high number of internal server errors on requests to your table (as seen in the the section called "SystemErrors" metric), you should investigate further.

Topics

- Investigating internal server errors
- Minimizing the impact from internal server errors
- Improving operational awareness

Investigating internal server errors

If you encounter internal server errors in your DynamoDB table, consider these options:

1. **Check the AWS Health Dashboard.**

   To identify the issue, the first step is to check the AWS Service Health Dashboard and your AWS Account Health Dashboard. These dashboards provide valuable information about any service-wide issues, impacted tables, ongoing problems, and the root cause after the issue has been resolved.

   Reviewing the details in these dashboards will give you a better understanding of the current status of the AWS services you're using and any potential problems affecting your account. This information can help you determine the next steps to address the issue and minimize any disruptions to your operations.

2. **Reach out to Support.**

   If you observe prolonged, sustained errors in your requests, it might indicate an issue with the service. As a general rule, if you see an overall failure rate of 1% or more over the last 15 minutes, it's an appropriate time to escalate the issue to the AWS Support team. See, DynamoDB Service Level Agreement to learn more.

   When opening a case with the AWS Support team, provide the following details to help expedite the troubleshooting process:

   - Impacted DDB; tables or secondary indexes
   - Time window when the errors were observed
   - DynamoDB request IDs, such as `4KBNVRGD25RG1KE09UT4V3FQDJVV4KQNSO5AEMVJF66Q9ASUAAJG`, which you can find in your application logs.

   Including these details in the support case will help the AWS team understand the problem and provide a faster resolution. If you don't have the request IDs, you should still log the case with the other available details.

Minimizing the impact from internal server errors

If internal server errors happen when using DynamoDB, minimize the impact of these on your application, consider the following best practices:

- Use backoffs and retries – DynamoDB's default SDK behaviors are designed to find the right balance for most applications in terms of back-off and retry strategy. However, you can

adjust these settings based on your application's tolerance for downtime and performance requirements. Learn more about back-offs and retries to understand how you can fine-tune these retry settings.

- Use eventually consistent reads – If your application doesn't require strongly consistent reads, consider using eventually consistent reads. These reads are lower cost and less likely to experience transient issues due to internal server errors as it would be served from any of the available Storage Nodes. For more information, see DynamoDB read consistency.

Improving operational awareness

Maintaining high availability and reliability of your applications is crucial in today's digital landscape. One key aspect of this is proactively monitoring for internal server errors (ISEs) in your DynamoDB tables and global secondary indexes (GSIs). By creating CloudWatch alarms to monitor these errors, you can gain better operational awareness and be alerted to potential issues before they impact your end-users. This approach aligns with the Operational Excellence pillar of the AWS Well-Architected Framework, ensuring your DynamoDB workload is optimized for performance, security, and reliability.

Creating CloudWatch alarms

You should have CloudWatch alarms set on your DynamoDB tables to receive notifications for consistently high numbers of internal server errors instead of observing the metrics manually. This ties with the operational excellence pillar of the Well-Architected framework for any workload on AWS. See Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload to learn more about Well-Architecting your DynamoDB tables.

When you create an alarm on the the section called “SystemErrors” metric, specify both the `TableName` and `Operation` dimensions (or `TableName` and `GlobalSecondaryIndexName` for a global secondary index). DynamoDB emits `SystemErrors` per operation, not on `TableName` alone, so an alarm that specifies only `TableName` stays in the `INSUFFICIENT_DATA` state and never alerts.

Troubleshooting latency issues in Amazon DynamoDB

If your workload appears to experience high latency, you can analyze the CloudWatch `SuccessfulRequestLatency` metric, and check the average latency and median latency through percentile metrics (p50) to see if it’s related to DynamoDB. Some variability in the reported

`SuccessfulRequestLatency` is normal, and occasional spikes (particularly in the `Maximum` statistic and high percentiles) should not be cause for concern. However, if the `Average` statistic or p50 (median) shows a sharp increase and persists, you should check the AWS Service Health Dashboard and your Personal Health Dashboard for more information. Some possible causes include the size of the item in your table (a 1 KB item and a 400 KB item will vary in latency) or the size of the query (10 items versus 100 items).

The percentile metrics (p99, p90, etc.) can help you better understand your latency distribution. For example:

- p50 (median) shows the typical latency for your workload.
- p90 shows that 90 percent of requests are faster than this value.
- p99 helps identify the worst-case latency affecting 1 percent of requests.

High p99 values with normal p50 values might indicate sporadic issues affecting a small portion of requests, while consistently elevated p50 values might suggest some performance degradation.

> **Note**
>
> To analyze custom percentile values (such as p99.9), you can manually enter the desired percentile (e.g., p99.9) in the CloudWatch metric statistic field. This allows you to evaluate latency distributions beyond the default percentiles listed in the dropdown.

Some variation in latency metrics, particularly in higher percentiles, is expected and can be seen as a result of DynamoDB-driven background operations that help maintain high availability and durability for your data stored in DynamoDB tables or transient infrastructure issues.

If necessary, consider opening a support case with AWS Support, and continue to assess any available fall-back options for your application (such as evacuation of a Region if you have a multi-Region architecture) according to your runbooks. You should log request IDs for slow requests for providing these IDs to AWS Support when you open a support case.

The `SuccessfulRequestLatency` metric only measures latency which is internal to the DynamoDB service — client side activity and network trip times are not included. To learn more about overall latency for calls from your client to the DynamoDB service, you can enable latency metric logging in your AWS SDK.

> **Note**
>
> For most singleton operations (operations which apply to a single item by fully specifying the primary key's value), DynamoDB delivers single-digit millisecond `Average SuccessfulRequestLatency`. This value does not include the transport overhead for the caller code accessing the DynamoDB endpoint. For multi-item data operations, the latency will vary based on factors such as size of the result set, the complexity of the data structures returned, and any condition expressions and filter expressions applied. For repeated multi-item operations to the same data set with the same parameters, DynamoDB will provide highly consistent `Average SuccessfulRequestLatency`.

Consider one or more of the following strategies to reduce latency:

- **Reuse connections:** DynamoDB requests are made through an authenticated session over HTTPS by default. Initiating the connection requires multiple round-trips and takes time so the latency of the first request is higher than following requests that reuse the connection. Requests over an already initialized connection deliver DynamoDB's consistent low latency. To avoid the latency overhead of establishing new connections, you may want to implement a "keep-alive" mechanism by sending a `GetItem` request every 30 seconds if no other requests are made.
- **Use eventually consistent reads:** If your application doesn't require strongly consistent reads, consider using the default eventually consistent reads. Eventually consistent reads have lower cost and can come from multiple availability zones, allowing selection of an availability zone co-located to the requester which decreases latency. For more information, see DynamoDB read consistency.
- **Implement request hedging:** For very low p99 latency requirements, consider implementing request hedging. With request hedging, if the initial request doesn't receive a response quickly enough, send a second equivalent request and let them race, first response wins. This improves tail latency at the cost of some extra requests. You can decide how long to wait before sending the second request. Hedging is easier for reads. For writes, use timestamp-based ordering to ensure hedged requests are treated as occurring at the time of the first attempt, preventing out-of-order updates. This approach has been discussed in Timestamp writes for write hedging in Amazon DynamoDB.
- **Adjust request timeout and retry behavior:** The path from your client to DynamoDB traverses many components, each designed with redundancy in mind. Consider the following aspects:
  - Network resiliency

- TCP packet timeouts
- DynamoDB's distributed architecture

Default SDK behaviors are optimized for most applications. However, you can implement a fail-fast strategy and adjust timeout settings. Requests taking significantly longer than normal are less likely to ultimately succeed. By failing fast and retrying, you may quickly succeed through a different path. This is similar to request hedging but ends the first request instead of allowing it to proceed.

Avoid setting timeout values too low. Overly low timeouts can lead to client-induced availability issues. For example, a 50-millisecond socket timeout could cause connection errors during network latency spikes, such as when approaching Amazon EC2 instance bandwidth limits for single-flow traffic. Carefully weigh the benefits of lower timeouts against potential risks to application availability, and prefer hedging to short timeouts.

For a helpful discussion on this topic, see Tuning AWS Java SDK HTTP request settings for latency-aware Amazon DynamoDB applications.

- **Reduce the distance between the client and DynamoDB endpoint:** If you have globally dispersed users, consider using Global tables - multi-active, multi-Region replication. With global tables, you can replicate your table to specified AWS Regions where you want the table to be available. You can place a copy of the data closer to the end user to reduce network latency during read and write operations. For more information about using DynamoDB global tables effectively, see Using Amazon DynamoDB global tables in AWS Prescriptive Guidance.
- **Use caching:** If your traffic is read heavy, consider using one of these caching services:
  - DynamoDB Accelerator (DAX): A fully managed, highly available, in-memory cache for DynamoDB that delivers up to a 10x performance improvement, from milliseconds to microseconds, even at millions of requests per second. For more information about DAX, see In-memory acceleration with DynamoDB Accelerator (DAX):
  - Amazon ElastiCache: A fully managed, in-memory caching service that can be integrated with DynamoDB to improve read performance using the cache-aside pattern. For more information, see Integrating Amazon DynamoDB and Amazon ElastiCache by using read-through caching in AWS Prescriptive Guidance.

Troubleshooting throttling in Amazon DynamoDB

DynamoDB implements throttling for two primary purposes: maintaining overall service performance and cost control. Throttling either serves as an intentional safeguard that prevents performance degradation when consumption rates exceed capacity or as a cost control mechanism when you reach maximum throughput or service quota limits. When throttling occurs, DynamoDB returns specific exceptions with detailed information about why the request was throttled and which resource was impacted. Each reason for throttling corresponds to specific CloudWatch metrics that provide additional insights into the frequency and patterns of throttling events.

The following diagram illustrates the four primary scenarios where DynamoDB implements protective throttling:

1. **Key range throughput exceeded (in both modes)**:

   Consumption directed at specific partitions exceeds the internal partition-level throughput limits.

2. **Provisioned throughput exceeded (in provisioned mode)**:

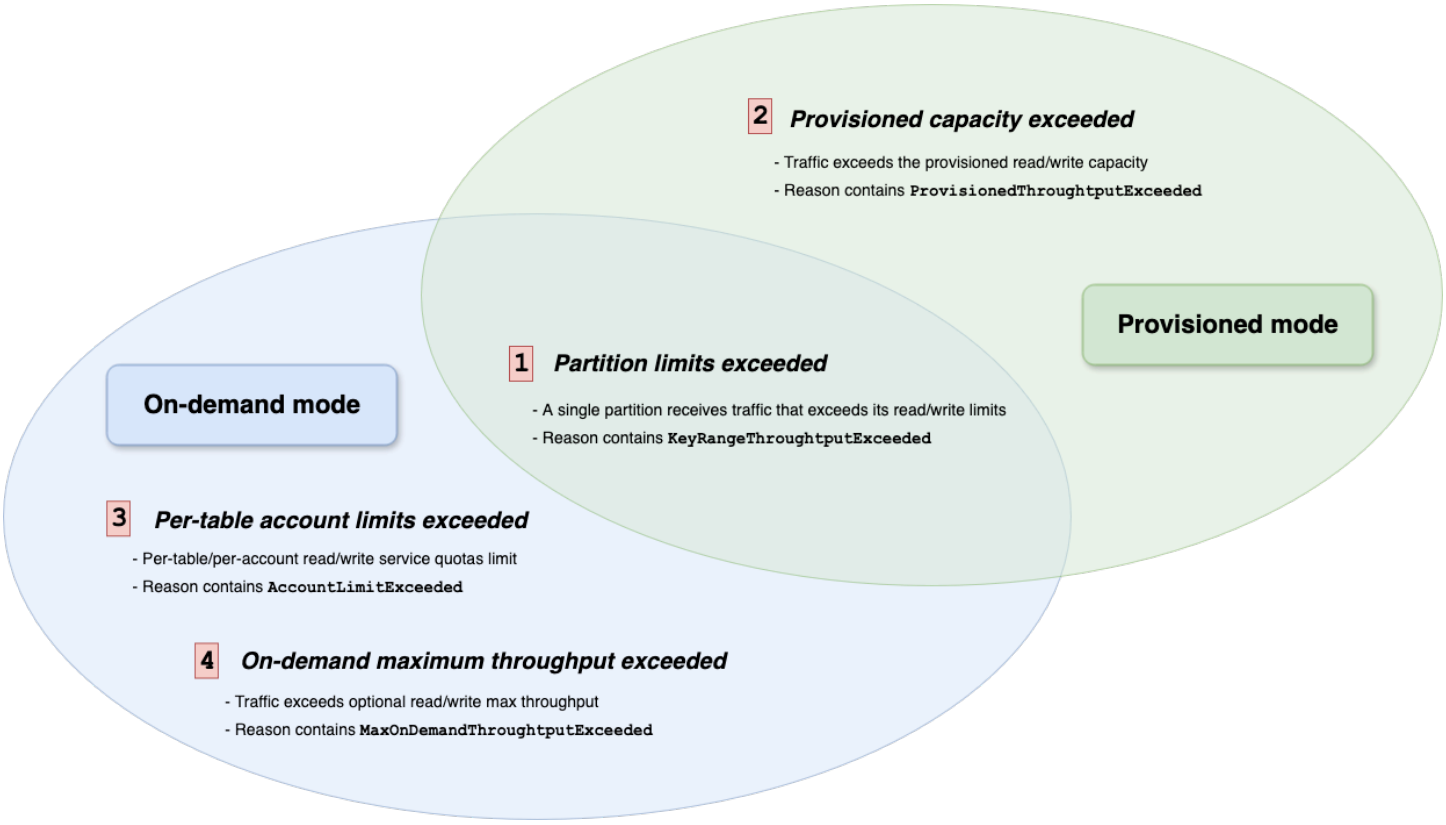
   Consumption exceeds the provisioned capacity units (read or write) configured for a table or a global secondary index (GSI).

3. **Account-level service quotas exceeded (in on-demand mode)**:

   Consumption causes a table or GSI to exceed the per-table account-level service quotas for read/write throughput in the current AWS Region. These quotas serve as backstop safeguards and can be increased.

4. **On-demand maximum throughput exceeded (in on-demand mode)**:

   Consumption exceeds the configured maximum throughput limits set for a table or GSI. These are limits you configure specifically for cost control purposes.



This guide is organized to help you understand and work with throttling in DynamoDB. First, this guide helps you identify the specific type of throttling affecting your workload through a diagnostic framework.

Then, the resolution guide section offers specific guidance for each throttling scenario, including CloudWatch metrics to monitor for detection and analysis, and recommended steps for optimization. By following this structured approach, you can better diagnose the root cause of throttling and implement the appropriate solution to make sure your DynamoDB tables operate efficiently.

To get started, follow the section called “Diagnosing throttling” to learn how to identify which type of throttling is affecting your workload and implement the recommended resolution strategy.

Topics

- Diagnosing throttling
- DynamoDB throttling resolution guide
- Understanding Global Secondary Index (GSI) write throttling and back pressure in DynamoDB
- CloudWatch throttling metrics

Diagnosing throttling

When your application experiences throttling, DynamoDB provides detailed exception information and targeted CloudWatch metrics to help you diagnose these events.

This section presents a systematic approach to understanding throttling events in your DynamoDB applications. It shows how to interpret throttling exceptions, correlate them with CloudWatch metrics for deeper insights, and understand what changes would reduce throttling in your DynamoDB applications.

Understanding throttling exceptions

When DynamoDB throttles a request, it returns specific exceptions with detailed diagnostic information. For example, in Java, these include `ProvisionedThroughputExceededException`, `RequestLimitExceeded`, or `ThrottlingException`.

Each exception includes `ThrottlingReasons`, a collection of individual `ThrottlingReason` containing two key fields to help you identify and understand the throttling:

- **A reason** - A concatenated field following the format `<ResourceType><OperationType><LimitType>`
- **A resource ARN** - The Amazon Resource Name (ARN) of the affected table or index

The reason field follows a consistent patern that helps you understand exactly what's happening:

- **ResourceType** (What is being throttled): `Table` or `Index`
- **OperationType** (What kind of operation): `Read` or `Write`
- **LimitType** (Why the throttling occurred):
  - `KeyRangeThroughputExceeded`: This occurs when a specific partition backing your table or index has consumed read or write capacity exceeding the internal per-partition throughput limits.
  - `ProvisionedThroughputExceeded`: This happens on a provisioned table or global secondary index when the read or write consumption rate has exceeded the provisioned amount.
  - `AccountLimitExceeded`: This happens on an on-demand table or index when the read or write consumption rate has exceeded the maximum consumption rate for a table and its indexes as set at the account level. You can request a raise in this quota.

- `MaxOnDemandThroughputExceeded`: This happens on an on-demand table or index when the read or write consumption rate has exceeded the user-provided maximum consumption rate configured for the table or index. You can raise this value yourself to any value up to the account limit or set to -1 to indicate no user-provided limit.

The resource ARN identifies exactly which table or index is being throttled:

- For tables: `arn:aws:dynamodb:[region]:[account-id]:table/[table-name]`
- For indexes: `arn:aws:dynamodb:[region]:[account-id]:table/[table-name]/index/[index-name]`

Examples of complete throttling reasons:

- `TableReadProvisionedThroughputExceeded`
- `IndexWriteAccountLimitExceeded`

This helps identify exactly what resource is being throttled, what type of operation caused it, and why the throttling occurred.

Example exceptions

Example 1: Provisioned capacity exceeded on a GSI

```
{
    "ThrottlingReasons": [
        {
            "reason": "IndexWriteProvisionedThroughputExceeded",
            "resource": "arn:aws:dynamodb:us-west-2:123456789012:table/CustomerOrders/
index/OrderDateIndex"
        }
    ],
    "awsErrorDetails": {
        "errorCode": "ProvisionedThroughputExceeded",
        "errorMessage": "The level of configured provisioned throughput for the index
 was exceeded",
        "serviceName": "DynamoDB",
        "sdkHttpResponse": {
            "statusText": "Bad Request",
            "statusCode": 400
```

```
        }
    }
}
```

In this example, the application receives a `ProvisionedThroughputExceededException` with the reason `IndexWriteProvisionedThroughputExceeded`. Writes to the `OrderDateIndex` are being throttled because the write consumption has exceeded the GSI's configured provisioned write capacity.

Example 2: On-demand maximum throughput exceeded

```
{
    "ThrottlingReasons": [
        {
            "reason": "TableReadMaxOnDemandThroughputExceeded",
            "resource": "arn:aws:dynamodb:us-east-1:123456789012:table/UserSessions"
        }
    ],
    "awsErrorDetails": {
        "errorMessage": "Throughput exceeds the maximum OnDemandThroughput configured
 on table or index",
        "errorCode": "ThrottlingException",
        "serviceName": "DynamoDB",
        "sdkHttpResponse": {
            "statusText": "Bad Request",
            "statusCode": 400
        }
    }
}
```

In this example, reads from the `UserSessions` table are being throttled because they exceed the configured maximum on-demand throughput limit on the table.

DynamoDB throttling diagnosis framework

When your application encounters throttling, follow these steps to diagnose and resolve the issue.

Step 1 - Analyze the `ThrottlingReason` details

1. Check the **reason** field to identify the specific reason for throttling. The reason details the type of resource throttled (table or index), the type of operation causing the throttling event (read or write), and the limit type that was exceeded (partition, provisioned throughput, account limit).

2. Check the **resourceArn** field to identify which resource (table or GSI) is being throttled.
3. Use this combined information to understand the full context of the throttling issue.

   For example, consider this scenario where you receive the following exception `ProvisionedThroughputExceededException` with a throttling reason `TableWriteKeyRangeThroughputExceeded`. The impacted resourceARN is `arn:aws:dynamodb:us-west-2:123456789012:table/CustomerOrders`.

   This combination informs you that write operations to your `CustomerOrders` table are being throttled. The throttling is occurring at the partition level (not the table level, which would show as `TableWriteProvisionedThroughputExceeded`). The root cause is that you've exceeded the maximum throughput capacity for a specific partition key value or range, indicating a hot partition issue.

   Understanding this relationship between the exception elements helps you implement the appropriate mitigation strategy - in this case, addressing the hot partition rather than increasing the table's overall provisioned capacity.

Step 2 - Identify and analyze the related CloudWatch metrics

1. **Identify your metrics:** Each throttling reason in DynamoDB directly corresponds to specific CloudWatch metrics that you can monitor to track and analyze throttling events. You can systematically derive the appropriate CloudWatch metric names from the throttling reason.
2. Match your throttling reason to the corresponding CloudWatch metrics using this reference table:

   Complete throttling reasons and CloudWatch metrics reference

Category	Throttling reason	Primary CloudWatch metrics
Provisioned capacity exceeded	TableReadProvisionedThroughputExceeded	ReadProvisionedThroughputThrottleEvents
	TableWriteProvisionedThroughputExceeded	WriteProvisionedThroughputThrottleEvents

Category	Throttling reason	Primary CloudWatch metrics
	IndexReadProvisionedThroughputExceeded	ReadProvisionedThroughputThrottleEvents (GSI)
	IndexWriteProvisionedThroughputExceeded	WriteProvisionedThroughputThrottleEvents (GSI)
Partition limits exceeded	TableReadKeyRangeThroughputExceeded	ReadKeyRangeThroughputThrottleEvents
	TableWriteKeyRangeThroughputExceeded	WriteKeyRangeThroughputThrottleEvents
	IndexReadKeyRangeThroughputExceeded	ReadKeyRangeThroughputThrottleEvents (GSI)
	IndexWriteKeyRangeThroughputExceeded	WriteKeyRangeThroughputThrottleEvents (GSI)
On-demand maximum exceeded	TableReadMaxOnDemandThroughputExceeded	ReadMaxOnDemandThroughputThrottleEvents
	TableWriteMaxOnDemandThroughputExceeded	WriteMaxOnDemandThroughputThrottleEvents
	IndexReadMaxOnDemandThroughputExceeded	ReadMaxOnDemandThroughputThrottleEvents (GSI)

Category	Throttling reason	Primary CloudWatch metrics
	IndexWriteMaxOnDemandThroughputExceeded	WriteMaxOnDemandThroughputThrottleEvents (GSI)
Account limits exceeded	TableReadAccountLimitExceeded	ReadAccountLimitThrottleEvents
	TableWriteAccountLimitExceeded	WriteAccountLimitThrottleEvents
	IndexReadAccountLimitExceeded	ReadAccountLimitThrottleEvents (GSIs)
	IndexWriteAccountLimitExceeded	WriteAccountLimitThrottleEvents (GSIs)

For example, if you received `IndexWriteProvisionedThroughputExceeded`, at a minimum, you should monitor the `WriteProvisionedThroughputThrottleEvents` CloudWatch metric for the specific index identified in the `ResourceArn`.

3. Monitor these metrics in CloudWatch to understand the frequency and timing of the throttling events, differentiate between read and write throttling, identify time patterns when throttling increases, and track your capacity utilization trends.

   DynamoDB publishes detailed metrics for each table and global secondary index. The metrics (`ReadThrottleEvents`, `WriteThrottleEvents`, and `ThrottledRequests`) aggregate all throttling events across your table and its indexes.

Step 3 - Identify your throttled keys and high access rates using CloudWatch Contributor Insights (for partition-related throttling)

If you identified partition-related issues in Step 1 (such as `KeyRangeThroughputExceeded` errors), CloudWatch Contributor Insights for DynamoDB can help you diagnose which specific keys are driving your traffic and experiencing throttling events in your table or index.

1. Enable CloudWatch Contributor Insights for your throttled table or index based on your `ResourceARN`.

   You can choose the *Throttled keys* mode to focus exclusively on the most throttled keys. This mode is ideal for continuous monitoring as it only processes events when throttling occurs. Alternatively, the *Accessed and throttled keys* mode helps you look for patterns in your most accessed keys.
2. Analyze the reports to identify problematic patterns. Look for keys with disproportionately high access or throttling rates, correlate throttling and traffic patterns. You can create integrated dashboards combining Contributor Insights graphs and DynamoDB CloudWatch metrics.
3. If no individual keys show disproportionately high access or throttling rates, key-range throttling might be caused by *unbounded sequential access* across a range of keys rather than a single hot key. When you run continued `Scan` operations, rate-limit the read traffic to stay below the per-partition maximum of 3,000 read units per second for a key range. To achieve higher overall read throughput, use parallel (segmented) scans to distribute read traffic more uniformly across partitions. Similarly, writing items in the same key order in which they are returned by a `Scan` concentrates writes on one key range at a time and can cause key-range throttling when the write rate to that range exceeds 1,000 write units per second. Rate-limit writes to a single key range to stay below that limit.

For detailed information about enabling and using CloudWatch Contributor Insights, see Using CloudWatch Contributor Insights for DynamoDB.

Step 4 - Determine the appropriate solution

After diagnosing the specific cause of throttling, implement recommended solution based on your specific context. The appropriate solution depends on multiple factors, including your throttling scenario, table's capacity mode, table and key design decisions, access patterns and query efficiency, global and secondary index configuration, and overall system architecture and integration points.

For detailed solutions to address your specific throttling scenarios, see the the section called "Resolution guide" section. This resource provides targeted remediation strategies customized to your particular throttling reason and capacity mode configuration.

Step 5 - Monitor your progress

1. Track your CloudWatch metrics that correspond to your throttling scenario.

2. Validate that your mitigation strategies are effective by observing a decrease in throttling events.

DynamoDB throttling resolution guide

This section provides targeted resolution guidance for each specific throttling reason that DynamoDB might return. Each entry includes suggested resolution approaches based on best practices and corresponding CloudWatch metrics to monitor.

DynamoDB implements 16 distinct throttling reasons across four main categories. Use the throttling reasons from your application's exception to navigate directly to the relevant guidance.

Key range throughput exceeded (hot partitions)

These throttling reasons occur when individual partitions exceed their throughput limits, affecting both provisioned and on-demand modes:

- TableReadKeyRangeThroughputExceeded
- TableWriteKeyRangeThroughputExceeded
- IndexReadKeyRangeThroughputExceeded
- IndexWriteKeyRangeThroughputExceeded

Provisioned throughput exceeded

These throttling reasons occur when consumption rates exceed provisioned capacity limits in provisioned mode:

- TableReadProvisionedThroughputExceeded
- TableWriteProvisionedThroughputExceeded
- IndexReadProvisionedThroughputExceeded
- IndexWriteProvisionedThroughputExceeded

Account limits exceeded

These throttling reasons occur when consumption rates exceed account-level throughput quotas in your AWS Region:

- TableReadAccountLimitExceeded
- TableWriteAccountLimitExceeded
- IndexReadAccountLimitExceeded
- IndexWriteAccountLimitExceeded

On-demand maximum throughput exceeded

These throttling reasons occur when consumption rates exceed configured maximum throughput limits in on-demand mode:

- TableReadMaxOnDemandThroughputExceeded
- TableWriteMaxOnDemandThroughputExceeded
- IndexReadMaxOnDemandThroughputExceeded
- IndexWriteMaxOnDemandThroughputExceeded

1- Key range throughput exceeded (hot partitions)

Amazon DynamoDB enforces specific throughput limits at the partition level for both table and global secondary index (GSI). Each partition has a maximum number of read capacity units (RCUs) and write capacity units (WCUs) per second. When partitions receive concentrated traffic that exceeds these limits, they experience throttling while other operations may remain underutilized, creating "hot partitions." DynamoDB's partition-level throttling operates independently for reads and writes - a partition might throttle reads while writes continue normally, or vice versa. This throttling can occur even when your table or GSI has sufficient overall capacity. To learn more about:

- DynamoDB partition limits and effective partition key design addressing hot partition prevention, see Best practices for designing and using partition keys effectively in DynamoDB.
- General partition concepts and data distribution, see Partitions in DynamoDB.
- Additional guidance and real-world scenarios for managing partition keys and throughput, see the section called “Additional resources”.

When individual partitions exceed their throughput limits, DynamoDB returns a `KeyRangeThroughputExceeded` throttling reason type in the throttling exception. The

information identifies that a partition is experiencing high traffic and which operation type (read or write) is causing the issue.

Key range throughput exceeded mitigation measures

This section provides resolution guidance for partition-level throttling scenarios. Before using this guide, make sure you have identified the specific throttling reasons from your application's exception handling, and determined the Amazon Resource Name (ARN) of the affected resource. For information on retrieving throttling reasons and identifying throttled resources, see the section called “Diagnosis framework”.

Before diving into specific throttling scenarios, first, check if the problem resolves automatically:

- DynamoDB often adapts to hot partitions through its automatic split-for-heat mechanism. If you see throttling events that stop after a short period, your table might have already adapted by splitting the hot partition. When partitions split, each new partition handles a smaller section of the keyspace, which can help distribute the load more evenly. In many cases, no further action is needed as DynamoDB has automatically resolved the issue.

  For more information about the *split-for-heat mechanism*, see the section called “Additional resources”.

If the throttling persists, refer to the specific throttling scenarios below for targeted remediation options:

- the section called “TableReadKeyRangeThroughputExceeded”
- the section called “TableWriteKeyRangeThroughputExceeded”
- the section called “IndexReadKeyRangeThroughputExceeded”
- the section called “IndexWriteKeyRangeThroughputExceeded”

TableReadKeyRangeThroughputExceeded

When this occurs

The consumption rate of one or more partitions in your DynamoDB table exceeds the partition's read throughput limit. This throttling occurs regardless of your table's total provisioned capacity and affects both provisioned and on-demand tables. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

For both provisioned and on-demand modes:

- **Pre-warm capacity:** If throttling persists, check if your table is limited by its the section called "Warm throughput" capacity. Use warm throughput or increase read provisioned capacity in advance for expected traffic increases. Increasing warm throughput improves your table's ability to handle sudden traffic spikes before throttling occurs. Over time, if your actual throughput consistently approaches the warm throughput levels, DynamoDB may split busy partitions based on observed usage patterns.
- **Identify your hot keys:** If the table didn't resolve it automatically and your warm throughput is high or raising it didn't help, you'll need to identify specific hot keys. Use the section called "Identifying hot keys using CloudWatch Contributor Insights" to determine if any particular partition key values are hot. This is a first step to target your mitigation efforts effectively. Note that identification might not always be straightforward, particularly with rolling hot partitions (where different partitions become hot over time) or when throttling is triggered by operations like scans. For these complex scenarios, you might need to analyze your application's access patterns and correlate them with the timing of throttling events.
- **Depending on your use case, consider using eventually consistent reads:** Switch from strongly consistent to eventually consistent reads, which consume half the RCUs and can immediately double your effective read capacity. For best practices on implementing eventually consistent reads to reduce read capacity consumption, see the section called "DynamoDB read consistency".
- **Improve partition key design:** As a long-term solution, consider the section called "Improving partition key design" to distribute access more evenly across partitions. This approach often provides the most comprehensive resolution to hot partition issues by addressing the root cause. However, it requires careful planning as it involves significant migration challenges.

TableWriteKeyRangeThroughputExceeded

When this occurs

The consumption rate of one or more partitions in your DynamoDB table exceeds the partition's write throughput limit. This throttling occurs regardless of your table's total provisioned capacity and affects both provisioned and on-demand tables. You can monitor the CloudWatch metrics in the section called "Common diagnosis and monitoring" to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

For both provisioned and on-demand modes:

- **Pre-warm capacity:** If throttling persists, check if your table is limited by its Understanding DynamoDB warm throughput capacity. Use warm throughput or increase write provisioned capacity in advance for expected traffic increases. Increasing warm throughput improves your table's ability to handle sudden traffic spikes before throttling occurs. Over time, if your actual throughput consistently approaches the warm throughput levels, DynamoDB might split busy partitions based on observed usage patterns.
- **Identify your hot keys:** If the table didn't resolve it automatically and your warm throughput is high or raising it didn't help, you'll need to identify specific hot keys. Use the section called "Identifying hot keys using CloudWatch Contributor Insights" to determine if any particular partition key values are hot. This is a first step to target your mitigation efforts effectively. Consider these common patterns:
  - If you see the same partition key appearing frequently in your throttling data, this indicates a concentrated hot key.
  - If you do not see repeated keys but are writing data in an ordered way (such as sequential timestamps or scan-based operations that follow keyspace order), you likely have rolling hot partitions where different keys become hot over time as your writes move through the keyspace.

  Note that write throttling can also occur with operations like `BatchWriteItem` or transactions that affect multiple items simultaneously. When individual items within a `BatchWriteItem` request are throttled, DynamoDB does not propagate these throttling errors to the application code. Instead, DynamoDB returns information about the unprocessed items in the response, which your application must handle by retrying those specific items. For transactions, the entire operation fails with a `TransactionCanceledException` if any item experiences throttling. For these complex scenarios, you might need to analyze your application's write patterns and data ingestion workflows, correlate them with the timing of throttling events, and implement appropriate retry handling strategies.
- **Improve partition key design:** As a long-term solution, consider the section called "Improving partition key design" to distribute access more evenly across partitions. This approach often provides the most comprehensive resolution to hot partition issues by addressing the root cause. However, it requires careful planning as it involves significant migration challenges.

IndexReadKeyRangeThroughputExceeded

When this occurs

The consumption rate of one or more partitions in your DynamoDB GSI exceeds the partition's read throughput limit. This throttling occurs regardless of your GSI's total provisioned capacity and affects both provisioned and on-demand tables. You can monitor the CloudWatch metrics in the section called "Common diagnosis and monitoring" to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

- **Pre-warm capacity:** If throttling persists, check if your GSI is limited by its Understanding DynamoDB warm throughput capacity. Use warm throughput or increase read provisioned capacity in advance for expected traffic increases. Increasing warm throughput improves your GSI's ability to handle sudden traffic spikes before throttling occurs. Over time, if your actual throughput consistently approaches the warm throughput levels, DynamoDB might split busy partitions based on observed usage patterns.
- **Identify your hot keys:** If the GSI didn't resolve it automatically and your warm throughput is high or raising it didn't help, you'll need to identify specific hot keys. Use the section called "Identifying hot keys using CloudWatch Contributor Insights" to determine if any particular partition key values are hot. This is a first step to target your mitigation efforts effectively. Note that for GSIs, the partition key distribution may differ significantly from your base table, creating different hot key patterns.
- **Redesign GSI partition keys:** Consider whether your GSI key design might be creating artificial hot spots (such as status flags, date-only keys, or boolean attributes) that concentrate reads on a small number of partitions. Consider using composite keys that combine the low-cardinality attribute with a high-cardinality attribute (e.g., "ACTIVE#customer123" instead of just "ACTIVE") or apply the section called "Write sharding" techniques to the base table items that affect GSI distribution to distribute writes across multiple partitions. While querying sharded data requires additional application logic to aggregate results, this approach prevents throttling by distributing access patterns more evenly.

IndexWriteKeyRangeThroughputExceeded

When this occurs

The consumption rate of one or more partitions in your DynamoDB GSI exceeds the partition's write throughput limit. This throttling occurs regardless of your GSI's total provisioned capacity and affects both provisioned and on-demand tables. You can monitor the CloudWatch metrics in the section called "Common diagnosis and monitoring" to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

- **Redesign GSI partition key:** Review your GSI partition key design to verify it has sufficient cardinality (uniqueness) to distribute writes evenly. A common cause of GSI write throttling is using low-cardinality attributes as GSI partition keys (such as status flags with only a few possible values). Even when your base table has well-distributed partition keys, your GSI can still experience hot partitions if its partition key concentrates writes to a small number of values. For example, if 80% of your items have status="ACTIVE", this creates a severe hot partition in a status-based GSI. Consider using composite keys that combine the low-cardinality attribute with a high-cardinality attribute (e.g., "ACTIVE#customer123" instead of just "ACTIVE") or apply the section called "Write sharding" techniques to the base table items that affect GSI distribution to distribute writes across multiple partitions. While querying sharded data requires additional application logic to aggregate results, this approach prevents throttling by distributing access patterns more evenly.
- **Pre-warm capacity:** Check if your GSI is limited by its Understanding DynamoDB warm throughput capacity. Use warm throughput or increase write provisioned capacity in advance for expected traffic increases. Increasing warm throughput improves your GSI's ability to handle sudden traffic spikes before throttling occurs. Over time, if your actual throughput consistently approaches the warm throughput levels, DynamoDB may split busy partitions based on observed usage patterns.
- **Optimize GSI projections:** Apply the section called "Optimizing GSI projections" techniques to reduce write volume to GSIs. Projecting fewer attributes can significantly reduce the write capacity consumed by each GSI update.

Common diagnosis and monitoring

When troubleshooting partition-level throttling, several CloudWatch metrics can help identify hot partitions and confirm the root cause.

Essential CloudWatch metrics

Monitor these key metrics to diagnose partition-level throttling:

- **Partition-level throttling events:** `ReadKeyRangeThroughputThrottleEvents` and `WriteKeyRangeThroughputThrottleEvents` track when individual partitions exceed their throughput limits. `ReadThrottleEvents` and `WriteThrottleEvents` track when any read or write requests exceed the provisioned capacity.
- **Capacity consumption:** `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` show overall usage patterns.

Resolution procedures

Identifying hot keys using CloudWatch Contributor Insights

Use this procedure to identify which partition keys are causing throttling.

1. Enable CloudWatch Contributor Insights on your table or GSI to track the most throttled keys. Consider keeping CloudWatch Contributor Insights enabled continuously for real-time throttling alerts by using the *Throttled keys* mode. This mode focuses exclusively on throttled requests by only processing events when throttling occurs. This targeted monitoring is a cost effective way to maintain continuous visibility into throttling issues.
2. Identify which keys are causing the hot partition issues.
3. (If the full *Accessed and throttled keys mode* is enabled) Analyze the access patterns over time to determine if hot keys are consistent or occur during specific periods.

Improving partition key design

Use this approach when you can modify your table schema to better distribute traffic across partitions. When possible, this is the most effective long-term solution for hot partition issues. Ideally, partition key design should be carefully considered during the initial table design phase.

Partition key redesign represents a fundamental change to your data model that impacts your entire application ecosystem. Before proceeding with this approach, carefully consider these significant limitations:

- **Data migration complexity:** Redesigning partition keys requires migrating all existing data, which can be resource-intensive and time-consuming for large tables.
- **Application code changes:** All application code that reads or writes to the table must be updated to use the new key structure.

- **Production impact:** Migrating to a new key design often requires downtime or complex dual-write strategies during transition.

For comprehensive guidance and principles on partition key design, see the section called "Partition key design" and the section called "Distributing workloads".

Optimizing GSI projections

Review your application's query patterns to determine exactly which attributes need to be available when querying the GSI, and limit your projections to just those attributes. When you update attributes that aren't projected into a GSI, no write operation occurs on that GSI, reducing write throughput consumption during updates. This targeted projection strategy optimizes both performance and cost while still supporting your application's query requirements. Note that projecting fewer attributes reduces write capacity consumption but might require additional base table reads.

For more information about efficient projection strategies, see Best Practices for Using Secondary Indexes in DynamoDB.

Additional resources

The following blog posts provide hands-on examples and practical details for the concepts covered in this guide:

- For hands-on guidance about scaling DynamoDB and managing hot partitions, see Part 1: Scaling DynamoDB - How partitions, hot keys, and split for heat impact performance.
- For detailed information about how DynamoDB's split-for-heat mechanism works, its benefits, and implementation details, see Part 3: Summary and best practices.
- For detailed write sharding strategies, see the section called "Write sharding".

2- Provisioned throughput exceeded

Provisioned capacity throttling occurs when your application's consumption rate exceeds the read or write capacity units (RCUs/WCUs) configured for your tables or global secondary indexes. While DynamoDB provides burst capacity to handle occasional traffic spikes, sustained requests beyond your provisioned limits result in throttling. When this happens, DynamoDB returns a `ProvisionedThroughputExceeded` throttling reason type in the throttling exception. The

reason identifies whether the issue is with read or write operations and whether it affects the base table or a global secondary index.

Throttling can occur regardless of whether Auto Scaling is enabled. Auto Scaling adapts to increases in consumption, but it does not respond instantly and it is constrained by the maximum capacity limits you configure. This means throttling can still occur during sudden traffic spikes or when consumption exceeds your maximum Auto Scaling limits.

Provisioned throughput exceeded mitigation measures

This section provides resolution guidance for provisioned capacity throttling scenarios. Before using this guide, make sure you have identified the specific throttling reason from your application's exception handling, and determined the Amazon Resource Name (ARN) of the affected resource. For information on retrieving throttling reasons and identifying throttled resources, see the section called “Diagnosis framework”.

Before diving into specific throttling scenarios, first consider if the throttling is actually a problem that needs resolution:

- Occasional throttling is normal and expected in well-optimized DynamoDB applications. Throttling simply means you're consuming 100% of what you've provisioned. If your application handles throttling gracefully with retries and your overall performance meets requirements, the throttling might not require immediate action.
- However, if throttling is causing unacceptable client-side latency, degrading user experience, or preventing critical operations from completing in a timely manner, then proceed with the mitigation options below.

When you need to address throttling issues, first determine if your throttling is caused by:

- **Temporary traffic spikes:** Short-duration increases in traffic that exceed your provisioned capacity but aren't sustained. These require different strategies than continuous high traffic.
- **Continuous high traffic:** Sustained workloads that consistently exceed your provisioned capacity.

For traffic spikes, consider the strategies from the *Handle traffic spikes with Amazon DynamoDB provisioned capacity* blog in the section called “Additional resources”.

For continuous high traffic, consider the capacity adjustment options below:

- the section called “TableReadProvisionedThroughputExceeded”

- the section called “TableWriteProvisionedThroughputExceeded”
- the section called “IndexReadProvisionedThroughputExceeded”
- the section called “IndexWriteProvisionedThroughputExceeded”

TableReadProvisionedThroughputExceeded

When this occurs

Your application's read consumption rate exceeds the provisioned read capacity units (RCUs) configured for your table. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Resolution approach

Consider these strategies to resolve read capacity throttling:

- **Switch to on-demand capacity mode:** Consider switching your table to on-demand if you experience frequent throttling from traffic spikes. On-demand eliminates provisioning concerns and automatically scales with your workload.
- **If staying with provisioned mode and Auto Scaling is not enabled:**
  - Consider increasing the table read capacity.
  - Enable Auto Scaling for read capacity on your table.
- **If Auto Scaling is enabled (default for tables created in the console):**
  - Optimize your table's read Auto Scaling parameters.

TableWriteProvisionedThroughputExceeded

When this occurs

Your application's write consumption rate exceeds the provisioned write capacity units (WCUs) configured for your table. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Resolution approach

Consider these strategies to resolve write capacity throttling:

- **Switch to on-demand capacity mode:** Consider switching your table to on-demand if you experience frequent throttling from traffic spikes. On-demand eliminates provisioning concerns and automatically scales with your workload.
- **If staying with provisioned mode and Auto Scaling is not enabled:**
  - Consider increasing the table write capacity.
  - Enable Auto Scaling for write capacity on your table.
- **If Auto Scaling is enabled (default for tables created in the console):**
  - Optimize your table's write Auto Scaling parameters.

IndexReadProvisionedThroughputExceeded

When this occurs

Read consumption on a Global Secondary Index (GSI) exceeds the GSI's provisioned read capacity units (RCUs). You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Resolution approach

Consider these strategies to resolve GSI read capacity throttling:

- **Switch to on-demand capacity mode:** Consider switching the base table to on-demand if you experience frequent throttling from traffic spikes. On-demand eliminates provisioning concerns and automatically scales with your workload.
- **If staying with provisioned mode and Auto Scaling is not enabled:**
  - Consider increasing the GSI read capacity.
  - Enable Auto Scaling for read capacity on your GSI.
- **If Auto Scaling is enabled (default for tables created in the console):**
  - Optimize your GSI's read Auto Scaling parameters.

IndexWriteProvisionedThroughputExceeded

When this occurs

Updates to items in the base table trigger writes to a GSI that exceed the GSI's provisioned write capacity. This causes back-pressure throttling on base table writes. You can monitor the

CloudWatch metrics in the section called "Common diagnosis and monitoring" to analyze your throttling event.

Resolution approach

Consider these strategies to resolve GSI write capacity throttling:

- **Switch to on-demand capacity mode:** Consider switching the base table to on-demand if you experience frequent throttling from traffic spikes. On-demand eliminates provisioning concerns and automatically scales with your workload.
- **If staying with provisioned mode and Auto Scaling is not enabled:**
  - Consider increasing the GSI write capacity.
  - Enable Auto Scaling for write capacity on your GSI.
- **If Auto Scaling is enabled (default for tables created in the console):**
  - Optimize your GSI's write Auto Scaling parameters.

Common diagnosis and monitoring

When troubleshooting throughput errors, several CloudWatch metrics can help identify the root cause.

Essential CloudWatch metrics

Monitor these key metrics to diagnose provisioned capacity throttling:

- **Throttling events:** `ReadProvisionedThroughputThrottleEvents` and `WriteProvisionedThroughputThrottleEvents` track when requests are throttled for this reason.`ReadThrottleEvents` and `WriteThrottleEvents` track when any read or write requests exceed the provisioned capacity.
- **Capacity consumption:** `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` show actual usage.
- **Provisioned capacity:** `ProvisionedReadCapacityUnits` and `ProvisionedWriteCapacityUnits` show configured limits.

Resolution procedures

Increasing table throughput capacity

Use this procedure when Auto Scaling is not enabled and you need immediate capacity increase.

1. Update your table's provisioned capacity using the DynamoDB console, AWS CLI, or SDK:
   - **For read capacity:** Increase the `ReadCapacityUnits` parameter, which specifies the maximum number of strongly consistent reads consumed per second before DynamoDB throttles requests.
   - **For write capacity:** Increase the `WriteCapacityUnits` parameter, which specifies the maximum number of writes consumed per second before DynamoDB throttles requests.
2. Verify that your new capacity settings don't exceed the per-table throughput quotas and that your total account consumption remains below the per-account throughput quotas for your Region. If you're approaching these limits, consider switching to on-demand capacity mode instead.

Configuring table Auto Scaling to adjust the read or write capacity of your table or GSI

Configure DynamoDB Auto Scaling to automatically adjust read or write capacity based on traffic patterns. You can configure Auto Scaling independently for both tables and GSIs, with separate controls for read and write capacity units.

1. Enable Auto Scaling for read capacity, write capacity, or both on your table or GSI.
2. Set a target utilization percentage with headroom for traffic spikes.

> **Note**
>
> Lower target utilization increases costs and scaling frequency. Targets below 40% might cause over-provisioning. Monitor usage patterns and costs to balance performance and efficiency.

3. Set capacity boundaries:
   - **Minimum RCUs/WCUs:** Maintains sufficient capacity during low-traffic periods.
   - **Maximum RCUs/WCUs:** Accommodates peak traffic demands and protects against runaway scaling events.

For guidance on configuring and managing DynamoDB Auto Scaling, see Managing throughput capacity automatically with DynamoDB Auto Scaling.

> **Note**
>
> Auto Scaling typically takes several minutes to respond to traffic changes. For sudden traffic spikes, your table's burst capacity provides immediate protection while Auto Scaling adjusts. Configure target utilization with adequate headroom to allow time for scaling operations and to preserve burst capacity for unexpected demand.

Optimizing your table's or index's read or write Auto Scaling settings

Use this procedure when Auto Scaling is enabled but throttling still occurs. You can tune Auto Scaling independently for both tables and global secondary indexes (GSIs), with separate controls for read and write capacity units.

- **Adjust target utilization:** Consider lowering the target utilization for your table or GSIs to trigger scaling earlier before throttling occurs. Make sure that you monitor your traffic after making these adjustments. See the section called "Configuring table Auto Scaling to adjust the read or write capacity of your table or GSI" for more information about capacity consumption and cost implications.
- **Review capacity boundaries:** Make sure your minimum and maximum capacity settings align with your actual workload patterns.

Switching to on-demand capacity mode

For general information about switching capacity modes, see the section called "Switching capacity modes". Refer to the Service Quotas to learn about specific constraints when switching mode.

Increasing GSI throughput capacity

Use this procedure when Auto Scaling is not enabled on your GSI or you need immediate capacity increase.

1. Update the GSI's provisioned capacity using the DynamoDB console, AWS CLI, or SDK:

- **For read capacity:** Increase the `ReadCapacityUnits` parameter for the specific GSI, which specifies the maximum number of reads the GSI can consume per second before DynamoDB throttles requests. Note that GSIs only support eventually consistent reads.
- **For write capacity:** Increase the `WriteCapacityUnits` parameter for the specific GSI, which specifies the maximum number of writes the GSI can consume per second before DynamoDB throttles requests.

2. Make sure that the GSI's provisioned throughput capacity remains within the per-account and per-table throughput quotas.

Additional resources

- For detailed information about handling traffic spikes in DynamoDB provisioned capacity tables, including various strategies from utilizing Auto Scaling and burst capacity to strategic throttle management, see Handle traffic spikes with Amazon DynamoDB provisioned capacity.
- For information about how to use a cron expression to schedule a scaling policy, see Optimize costs by scheduling provisioned capacity for DynamoDB.
- For hands-on information about monitoring and analyzing throughput utilization patterns for your DynamoDB tables in provisioned capacity mode, see How to evaluate throughput utilization for Amazon DynamoDB tables in provisioned mode.

3- Account limits exceeded

On-demand tables do not have provisioned capacity levels to manage, but DynamoDB enforces account-level throughput limits to prevent runaway execution and achieve fair resource usage across all customers. These per-table account limits serve as adjustable safeguards, set for each account and Region combination. When your read or write consumption rate exceeds these limits, DynamoDB returns an `AccountLimitExceeded` throttling reason type in the throttling exception. The default per-table account limits automatically apply when tables do not have custom maximum throughput settings configured. You can optionally configure maximum throughput settings for finer cost control and predictability, or request quota increases through the the section called “Quotas” console if your application requirements exceed the default limits.

Account limit exceeded mitigation measures

This section provides resolution guidance for account limit throttling scenarios. Before using this guide, make sure you have identified the specific throttling reasons from your application's

exception handling, and determined the Amazon Resource Name (ARN) of the affected resource. For information on retrieving throttling reasons and identifying throttled resources, see the section called “Diagnosis framework”.

Before diving into specific throttling scenarios, first determine if action is actually needed:

- **Evaluate performance impact:** Check if your application is still meeting its performance requirements despite the throttling. Many applications operate successfully at or near account limits, particularly during bulk operations or data migrations.
- **Review throttling patterns:** If throttling is intermittent and your application handles retries effectively, the current limits might be sufficient for your workload.

If your application performs acceptably even when occasionally hitting account limits, you might choose to simply monitor the situation rather than implementing immediate changes.

If you determine that throttling is causing unacceptable performance issues or reliability concerns, select a specific throttling reason below to find recommended mitigation options:

- the section called “TableReadAccountLimitExceeded”
- the section called “TableWriteAccountLimitExceeded”
- the section called “IndexReadAccountLimitExceeded”
- the section called “IndexWriteAccountLimitExceeded”

TableReadAccountLimitExceeded

When this occurs

Your table's read consumption has exceeded the account-level per-table read throughput quota for your Region. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Resolution approach

Use the following steps to resolve this throttling:

- **Request quota increases:**

  Request an increase to the per-table read throughput limit (Quota code L-CF0CBE56). For detailed steps on how to submit the request, see Requesting per-table quota increases.

TableWriteAccountLimitExceeded

When this occurs

Your table's write consumption has exceeded the account-level per-table write throughput quota for your Region. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Resolution approach

Use the following steps to resolve this throttling:

- **Request quota increases:** Request an increase to the per-table write throughput limit (Quota code L-AB614373). For detailed steps on how to submit the request, see Requesting per-table quota increases.

IndexReadAccountLimitExceeded

When this occurs

The read operations directed at a Global Secondary Index (GSI) consume more throughput than your account's per-table read quota allows in your current AWS Region. The account-level per-table read throughput quota applies collectively to a table and all its GSIs combined. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Resolution approach

Choose the appropriate resolution based on your account's capacity distribution:

- **Request quota increases:** Request an increase to the per-table read throughput limit (Quota code L-CF0CBE56). For detailed steps on how to submit the request, see Requesting per-table quota increases.
- **Optimize GSI usage:** Review GSI design and query patterns to reduce unnecessary read capacity consumption.

IndexWriteAccountLimitExceeded

When this occurs

Write operations to your base table generate corresponding updates to a GSI that collectively exceed the account-level per-table write throughput quota for your AWS Region. Every write to a base table item that contains attributes indexed by a GSI trigger a corresponding write operation to that GSI. These combined write operations count toward your per-table write throughput quota. You can monitor the CloudWatch metrics in the section called "Common diagnosis and monitoring" to analyze the patterns and timing of these throttling events and identify which operations are causing the excessive GSI write activity.

Resolution approach

Choose the appropriate resolution based on your account's capacity distribution:

- **Request quota increases:** Request an increase to the per-table write throughput limit (Quota code L-AB614373) to accommodate higher GSI write traffic from base table operations. The per-table write throughput quota applies to the entire table, including all of its GSIs. For detailed steps on how to submit the request, see Requesting per-table quota increases.
- **Optimize GSI projections:** Review GSI projections and design to reduce write volume to GSIs.

Common diagnosis and monitoring

When troubleshooting account limit exceeded throttling events, several CloudWatch metrics can help identify whether you're hitting per-table or account-wide limits and understand your capacity distribution patterns.

Essential CloudWatch metrics

Monitor these key metrics to diagnose account limit throttling:

- **Account limit throttling events:** `ReadAccountLimitThrottleEvents` and `WriteAccountLimitThrottleEvents` track when requests are throttled due to account-level limits. `ReadThrottleEvents` and `WriteThrottleEvents` track when any read or write requests exceed the provisioned capacity.
- **Capacity consumption by resource:** `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` for each table and GSI show individual resource usage.
- **Account-wide consumption:** Use CloudWatch metric math expressions to sum consumed capacity across all tables and GSIs to monitor total account usage.

Resolution procedures

Requesting per-table quota increases

If your applications need to operate beyond the current per-table throughput limits, you should submit a quota increase request using the procedure below. Each DynamoDB table in your AWS account (together with all its associated GSIs) is subject to these throughput quotas within a specific Region. These quotas represent the maximum read or write capacity that any individual table and its GSIs can collectively consume. They apply independently to each table rather than as an aggregate across all tables in your account.

Optionally, you can also set lower limits on a per-table or per-GSI basis by configuring their maximum on-demand throughput settings.

1. Identify the specific quota that needs to be increased:
   - **Per-table read throughput limit** (Quota code L-CF0CBE56): Default 40,000 RCUs per table
   - **Per-table write throughput limit** (Quota code L-AB614373): Default 40,000 WCUs per table
2. Use the AWS Service Quotas console to request an increase:
   - Navigate to the DynamoDB service in Service Quotas
   - Find the appropriate quota using the quota code
   - Request an increase based on your projected peak usage
3. Provide justification for the increase, including:
   - Current usage patterns and peak traffic requirements
   - Business justification for the increased capacity
   - Timeline for when the increased capacity is needed

> **Note**
>
> Quota increases typically take 24-48 hours to process. Plan your requests accordingly and consider temporary mitigation strategies while waiting for approval.

Optimizing GSI projections and design

Optimize your Global Secondary Index (GSI) projections and design to reduce capacity consumption and improve performance.

Selective projection strategies

If your queries only need to access a few attributes, projecting only those attributes reduces the amount of data written to the GSI when base table items change. For details on projection types, see Projections for Global Secondary Indexes.

1. Analyze query patterns: Review your application's query patterns to identify which attributes are actually accessed through the GSI.
2. Use selective projections: Only project attributes that are actually needed in queries to reduce write volume.
3. Consider `KEYS_ONLY`: If your queries only need the key attributes, use `KEYS_ONLY` projection to minimize write volume.
4. Balance read vs. write trade-offs: Projecting fewer attributes reduces write capacity consumption but might require additional base table reads.

Sparse GSI implementation

Sparse GSIs contain only items that have the indexed attribute, rather than all items from your base table. This reduces partition density and improves performance when you frequently query specific subsets of data.

1. Design GSIs that only include items with specific attribute values.
2. Implement conditional indexing by only setting the GSI partition key attribute on items that should be indexed.
3. Use composite keys in sparse GSIs (e.g., status#timestamp) to further distribute traffic within the subset of indexed items.

For more information about implementing these strategies, see Best Practices for Using Secondary Indexes in DynamoDB.

4- On-demand maximum throughput exceeded

When you configure an on-demand table or GSI, you can optionally set a maximum throughput limit (`MaxReadRequestUnits` and `MaxWriteRequestUnits`) at the table or index level to prevent runaway costs or protect downstream systems from being overwhelmed. For more information about maximum throughput, see the section called “DynamoDB maximum throughput for on-demand tables”.

When your read or write consumption exceeds these self-imposed limits, additional requests that would exceed the limit receive quick throttle responses. DynamoDB returns exceptions with a `MaxOnDemandThroughputExceeded` throttling reason type, indicating which resource has reached its throughput boundary.

On-demand maximum throughput exceeded throttling

This section provides resolution guidance for on-demand maximum throughput exceeded throttling scenarios. Before using this guide, make sure you have identified the specific throttling reasons from your application's exception handling, and determined the Amazon Resource Name (ARN) of the affected resource. For information on retrieving throttling reasons and identifying throttled resources, see the section called “Diagnosis framework”.

Before diving into specific throttling scenarios, first consider whether action is actually needed:

- **Evaluate your maximum throughput settings:** These limits were intentionally configured to control costs or protect downstream systems. If you're receiving `MaxOnDemandThroughputExceeded` throttling events, your limits are working as designed. Consider whether increasing these limits aligns with your original cost control or system protection goals.
- **Assess application impact:** Determine if the throttling is actually causing problems for your applications or users. If your applications handle retries effectively and meets their performance requirements despite occasional throttling, maintaining your current limits might be the appropriate choice.
- **Review traffic patterns:** Analyze whether the throttling represents an expected traffic pattern or an unusual spike. For predictable, recurring traffic patterns that consistently exceed your limits, adjusting the maximum throughput settings might be warranted. For temporary spikes, implementing better request distribution strategies might be more appropriate than raising limits.

If after consideration you determine that your maximum throughput settings need adjustment, refer to the specific throttling scenarios below for targeted remediation options:

- the section called “TableReadMaxOnDemandThroughputExceeded”
- the section called “TableWriteMaxOnDemandThroughputExceeded”
- the section called “IndexReadMaxOnDemandThroughputExceeded”
- the section called “IndexWriteMaxOnDemandThroughputExceeded”

TableReadMaxOnDemandThroughputExceeded

When this occurs

Your on-demand table has exceeded its configured maximum read throughput capacity. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

- **Increase maximum throughput limit:** Use the DynamoDB console, AWS CLI, or the DynamoDB `UpdateTable` API to increase the `MaxReadRequestUnits` value for the affected table, then monitor and adjust. This allows your table to handle higher read throughput before throttling occurs.
- **Remove the maximum limit:** Set `MaxReadRequestUnits` to `-1` to remove the ceiling, allowing scaling based on demand up to your account-level throughput quotas. This removes your custom limit but still maintains AWS's account-level safeguards. However, it's important to monitor spending closely after removing this limit, as your table can now consume significantly more capacity before hitting the account-level quotas.

TableWriteMaxOnDemandThroughputExceeded

When this occurs

Your on-demand table has exceeded its configured maximum write throughput capacity. You can monitor the CloudWatch metrics in the section called “Common diagnosis and monitoring” to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

- **Increase maximum throughput limit:** Use the DynamoDB console, AWS CLI, or the DynamoDB `UpdateTable` API to increase the `MaxWriteRequestUnits` value for the affected table, then monitor and adjust.
- **Remove the maximum limit:** Set `MaxWriteRequestUnits` to `-1` to remove the ceiling, allowing scaling based on demand up to your account-level throughput quotas. This removes your custom limit but still maintains AWS's account-level safeguards. However, it's important to monitor spending closely after removing this limit, as your table can now consume significantly more capacity before hitting the account-level quotas.

IndexReadMaxOnDemandThroughputExceeded

When this occurs

Read requests to a GSI in on-demand mode have exceeded the GSI's configured maximum read throughput capacity. You can monitor the CloudWatch metrics in the section called "Common diagnosis and monitoring" to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

- **Increase GSI maximum throughput limit:** Use the DynamoDB console, AWS CLI, or the DynamoDB `UpdateTable` API to increase the `MaxReadRequestUnits` value for the affected GSI, then monitor and adjust.
- **Remove the GSI maximum limit:** Set `MaxReadRequestUnits` to `-1` for the GSI to remove the ceiling, allowing scaling based on demand up to your account-level throughput quotas. This removes your custom limit but still maintains AWS's account-level safeguards. However, it's important to monitor spending closely after removing this limit.

IndexWriteMaxOnDemandThroughputExceeded

When this occurs

Updates to items in the base table trigger writes to a GSI in on-demand mode that exceed the GSI's configured maximum write throughput capacity, causing back-pressure throttling. You can monitor

the CloudWatch metrics in the section called "Common diagnosis and monitoring" to analyze your throttling event.

Remediation options

Consider these steps to address your throttling events:

- **Increase GSI maximum throughput limit:** Use the DynamoDB console, AWS CLI, or the DynamoDB `UpdateTable` API to increase the `MaxWriteRequestUnits` value for the affected GSI, then monitor and adjust.
- **Remove the GSI maximum limit:** Set `MaxWriteRequestUnits` to `-1` for the GSI to remove the ceiling, allowing scaling based on demand up to your account-level throughput quotas. This removes your custom limit but still maintains AWS's account-level safeguards. However, it's important to monitor spending closely after removing this limit.

Common diagnosis and monitoring

When troubleshooting on-demand maximum throughput exceeded throttling events, several CloudWatch metrics can help identify the root cause and scaling patterns.

Essential CloudWatch metrics

Monitor these key metrics to diagnose on-demand maximum throughput exceeded throttling:

- **Maximum throughput throttling events:** `ReadMaxOnDemandThroughputThrottleEvents` and `WriteMaxOnDemandThroughputThrottleEvents` track when requests are throttled due to exceeding maximum limits. `ReadThrottleEvents` and `WriteThrottleEvents` track when any read or write requests exceed the provisioned capacity.
- **Current maximum throughput configured for a table or global secondary index:** `OnDemandMaxReadRequestUnits` and `OnDemandMaxWriteRequestUnits` show the current maximum capacity limits.
- **Actual capacity consumption:** `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` show actual usage patterns.

Analysis approach

Follow these steps to confirm on-demand maximum throughput exceeded diagnosis:

1. Compare consumed capacity to maximum capacity limits - check if consumption consistently approaches or exceeds maximum limits.
2. Review throttling event frequency and timing to identify patterns. Look for sudden increases in consumed capacity that coincides with your throttling event.
3. Use CloudWatch Contributor Insights to identify which items or partition keys consume the most capacity.

Understanding Global Secondary Index (GSI) write throttling and back pressure in DynamoDB

GSI back-pressure throttling represents one of the most complex throttling scenarios in DynamoDB because it creates an indirect relationship between write operations and throttling—your application writes to a base table but experiences throttling due to capacity constraints on one or several indexes.

Understanding GSI back-pressure throttling

When you write to a DynamoDB table, any global secondary indexes (GSIs) on that table are updated asynchronously using an eventually consistent model. If a GSI doesn't have sufficient capacity to handle these updates, DynamoDB throttles writes to the base table to maintain data consistency. This is called *GSI back-pressure*. For more information about how GSIs work, see Global Secondary Indexes in DynamoDB.

Unlike direct table throttling where the resource being accessed is also the resource causing throttling, GSI back-pressure creates a dependency between the base table and its indexes. Even if your base table has ample capacity, writes will be throttled if any associated GSI cannot handle the update volume. This relationship is particularly important to understand because partition-level constraints apply independently to both the base table and each GSI—each has its own partition structure and corresponding throughput limits.

GSI partitioning is based on the GSI's partition key, which is often different from the base table's partition key. Even if your base table access is perfectly distributed across partitions, your GSI updates might still concentrate on specific partitions, creating hot spots in the GSI. For general best practices on partition key design for both tables and GSIs, see DynamoDB partition key design.

For example, if your base table uses `customerId` as a partition key (evenly distributed) but your GSI uses `status` as a partition key (with limited possible values like "active", "pending",

"closed"), updates to items with popular status values can create GSI hot partitions even when base table access is balanced. This creates a particularly challenging scenario. Your application might experience throttling due to GSI hot partitions even though both the base table and GSI have sufficient overall capacity and the base table's access pattern appears well-distributed.

Even though the throttling exception points to the GSI (through `ResourceArn`), the actual operation being throttled is the write to the base table. This can be confusing because your application is writing to the base table but receiving an exception about the GSI.

Types of GSI throttling

GSI back-pressure throttling manifests through different exception types depending on the specific capacity constraint:

- **GSI provisioned capacity exceeded:** Occurs when the GSI lacks sufficient write capacity units to handle updates from base table operations. This produces a `ProvisionedThroughputExceededException` with the reason `IndexWriteProvisionedThroughputExceeded`, and the `ResourceArn` points directly to the specific GSI experiencing capacity constraints.
- **GSI on-demand maximum throughput exceeded:** Occurs when GSI write operations surpass configured maximum limits on on-demand tables. This produces a `ThrottlingException` with the reason `IndexWriteMaxOnDemandThroughputExceeded`, identifying the specific GSI with configured throughput restrictions.
- **GSI partition limits exceeded:** Happens when individual GSI partitions exceed their throughput limits (hot partitions), even if overall GSI capacity appears sufficient. This generates a `ThrottlingException` with the reason `IndexWriteKeyRangeThroughputExceeded`, indicating hot partition issues on the specific GSI identified in the `ResourceArn`. This is particularly important because GSI partition distribution may differ significantly from the base table's partition distribution, creating hot spots in the GSI even when base table access is evenly distributed.
- **GSI account limits exceeded:** Triggers when write operations to a specific GSI exceed the per-table (or any individual GSI within that table) regional throughput boundaries set at the account level. DynamoDB returns a `ThrottlingException` with the reason `IndexWriteAccountLimitExceeded`, pointing to the GSI that pushed its usage beyond account limits. This throttling occurs independently for each GSI that surpasses the limit. For information about per-table, per-account,regional, service quotas, see the section called "Quotas".

CloudWatch throttling metrics

This page provides a comprehensive guide to CloudWatch metrics specifically designed to help you identify, diagnose, and resolve throttling issues in your DynamoDB tables and indexes.

General throttling metrics

- `ThrottledRequests`
  - Incremented by one when any event within a request is throttled, regardless of how many individual events within that request are throttled. For example, when updating an item in a table with Global Secondary Indexes (GSIs), multiple events occur: a write operation to the base table and a write operation to each index. If any of these individual events are throttled, the `ThrottledRequests` metric is only incremented once.

    This behavior is important to understand when monitoring and troubleshooting DynamoDB performance, as it might mask the true extent of throttling. For more comprehensive insights, compare the `ThrottledRequests` metric with the specific event-level metrics like `ReadThrottleEvents`, `WriteThrottleEvents`, and targeted metrics such as `ReadKeyRangeThroughputThrottleEvents` for example. The complete list of these cause-specific metrics is available in this page. Each metric corresponds to particular throttling reasons that are captured within the throttling exception. For guidance on retrieving and interpreting these reasons during throttling events, see the the section called “Diagnosing throttling” section which provides instructions for identifying and resolving the root causes of throttling issues.
- `ReadThrottleEvents`
  - Watch for requests that exceed the provisioned RCU for a table or GSI.
- `WriteThrottleEvents`
  - Watch for requests that exceed the provisioned WCU for a table or GSI.

Detailed throttling metrics by cause

On-Demand throughput throttling

- `ReadMaxOnDemandThroughputThrottleEvents`
  - Number of read requests throttled due to on-demand maximum throughput.
- `WriteMaxOnDemandThroughputThrottleEvents`
  - Number of write requests throttled due to on-demand maximum throughput.

Account-Level throttling

- `ReadAccountLimitThrottleEvents`
  - Number of read requests throttled due to account limits.
- `WriteAccountLimitThrottleEvents`
  - Number of write requests throttled due to account limits.

Partition-Level throttling

- `ReadKeyRangeThroughputThrottleEvents`
  - Number of read requests throttled due to partition limits.
- `WriteKeyRangeThroughputThrottleEvents`
  - Number of write requests throttled due to partition limits.

Capacity analysis metrics

- `OnlineIndexConsumedWriteCapacity`
  - When you add a new GSI to an existing table, DynamoDB performs a backfill operation that copies data from the base table to the new index. This process consumes write capacity units. The `OnlineIndexConsumedWriteCapacity` metric tracks this specific consumption.

    This consumption is separate from and additional to the regular write operations tracked by `ConsumedWriteCapacityUnits`. The regular `ConsumedWriteCapacityUnits` metric for a GSI does not include the write capacity consumed during the initial index creation process.
- `ProvisionedReadCapacityUnits` and `ProvisionedWriteCapacityUnits`
  - View how many provisioned read or write capacity units were consumed over the specified time period, for a table or a specified global secondary index.
  - Note that the `TableName` dimension returns `ProvisionedReadCapacityUnits` for the table only by default. To view the number of provisioned read or write capacity units for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.
- `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits`
  - View how many read or write capacity units were consumed over the specified time period. `ConsumedWriteCapacityUnits` does not include the write capacity consumed during the initial index creation process.

For more information on DynamoDB CloudWatch metrics, see DynamoDB Metrics and dimensions.

- AWS SDK for Node.js 2.x examples

Troubleshooting SSL/TLS connection establishment issues with DynamoDB

Amazon DynamoDB is in the process of moving our endpoints to secure certificates signed by the Amazon Trust Services (ATS) Certificate Authority instead of third-party Certificate Authority. In December 2017, we launched the EU-WEST-3 (Paris) Region with the secure certificates issued by the Amazon Trust Services. All new regions launched after December 2017 have endpoints with the certificates issued by the Amazon Trust Services. This guide shows you how to validate and troubleshoot SSL/TLS connection issues.

Testing your application or service

Most AWS SDKs and Command Line Interfaces (CLIs) support the Amazon Trust Services Certificate Authority. If you are using a version of the AWS SDK for Python (Boto) or CLI released before October 29, 2013, you must upgrade. The .NET, Java, PHP, Go, JavaScript, and C++ SDKs and CLIs do not bundle any certificates, their certificates come from the underlying operating system. The Ruby SDK has included at least one of the required CAs since June 10, 2015. Before that date, the Ruby V2 SDK did not bundle certificates. If you use an unsupported, custom, or modified version of the AWS SDK, or if you use custom trust store, you might not have the support needed for Amazon Trust Services Certificate Authority.

To validate access to DynamoDB endpoints, you will need to develop a test that accesses DynamoDB API or DynamoDB Streams API in the EU-WEST-3 region and validate that the TLS handshake succeeds. The specific endpoints you will need to access in such test are:

- DynamoDB: https://dynamodb.eu-west-3.amazonaws.com
- DynamoDB Streams: https://streams.dynamodb.eu-west-3.amazonaws.com

If your application does not support Amazon Trust Services Certificate Authority you will see one of the following failures:

- SSL/TLS Negotiation errors
- A long delay before your software receives an error indicating SSL/TLS negotiation failure. The delay time depends on the retry strategy and timeout configuration of your client.

Testing your client browser

To verify that your browser can connect to Amazon DynamoDB, open the following URL: https://dynamodb.eu-west-3.amazonaws.com. If the test is successful, you will see a message like this:

```
healthy: dynamodb.eu-west-3.amazonaws.com
```

If the test is unsuccessful, it will display an error similar to this: https://untrusted-root.badssl.com/.

Updating your software application client

Applications accessing DynamoDB or DynamoDB Streams API endpoints (whether through browsers or programmatically) will need to update the trusted CA list on the client machines if they do not already support any of the following CAs:

- Amazon Root CA 1
- Starfield Services Root Certificate Authority - G2
- Starfield Class 2 Certification Authority

If the clients already trust ANY of the above three CAs then these will trust certificates used by DynamoDB and no action is required. However, if your clients do not already trust any of the above CAs, the HTTPS connections to the DynamoDB or DynamoDB Streams APIs will fail. For more

information, please visit this blog post: https://aws.amazon.com/blogs/security/how-to-prepare-for-aws-move-to-its-own-certificate-authority/.

Updating your client browser

You can update the certificate bundle in your browser simply by updating your browser. Instructions for the most common browsers can be found on the browsers' websites:

- Chrome: https://support.google.com/chrome/answer/95414?hl=en
- Firefox: https://support.mozilla.org/en-US/kb/update-firefox-latest-version
- Safari: https://support.apple.com/en-us/HT204416
- Internet Explorer: https://support.microsoft.com/en-us/help/17295/windows-internet-explorer-which-version#ie=other

Manually updating your certificate bundle

If you can't access the DynamoDB API or DynamoDB Streams API then you need to update your certificate bundle. To do this, you need to import at least one of the required CAs. You can find these at https://www.amazontrust.com/repository/.

The following operating systems and programming languages support Amazon Trust Services certificates:

- Microsoft Windows versions that have January 2005 or later updates installed, Windows Vista, Windows 7, Windows Server 2008, and newer versions.
- MacOS X 10.4 with Java for MacOS X 10.4 Release 5, MacOS X 10.5 and newer versions.
- Red Hat Enterprise Linux 5 (March 2007), Linux 6, and Linux 7 and CentOS 5, CentOS 6, and CentOS 7
- Ubuntu 8.10
- Debian 5.0
- Amazon Linux (all versions)
- Java 1.4.2_12, Java 5 update 2, and all newer versions, including Java 6, Java 7, and Java 8

If you're still unable to connect, consult your software documentation, OS Vendor, or contact with AWS Support https://aws.amazon.com/support for further assistance.

Example tables and data for use in DynamoDB

The *Amazon DynamoDB Developer Guide* uses sample tables to illustrate various aspects of DynamoDB.

Table name	Primary key
ProductCatalog	Simple primary key: • `Id` (Number)
Forum	Simple primary key: • `Name` (String)
Thread	Composite primary key: • `ForumName` (String) • `Subject` (String)
Reply	Composite primary key: • `Id` (String) • `ReplyDateTime` (String)

The *Reply* table has a global secondary index named *PostedBy-Message-Index*. This index will facilitate queries on two non-key attributes of the *Reply* table.

Index name	Primary key
PostedBy-Message-Index	Composite primary key: • `PostedBy` (String) • `Message` (String)

For more information about these tables, see Step 1: Create a table in DynamoDB and Step 2: Write data to a DynamoDB table.

Sample data files

Topics

- ProductCatalog sample data
- Forum sample data
- Thread sample data
- Reply sample data

The following sections show the sample data files that are used for loading the *ProductCatalog*, *Forum*, *Thread* and *Reply* tables.

Each data file contains multiple `PutRequest` elements, each of which contain a single item. These `PutRequest` elements are used as input to the `BatchWriteItem` operation, using the AWS Command Line Interface (AWS CLI).

ProductCatalog sample data

```
{
    "ProductCatalog": [
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "101"
                    },
                    "Title": {
                        "S": "Book 101 Title"
                    },
                    "ISBN": {
                        "S": "111-1111111111"
                    },
                    "Authors": {
                        "L": [
                            {
                                "S": "Author1"
                            }
                        ]
                    },
                    "Price": {
                        "N": "2"
```

```
                    },
                    "Dimensions": {
                        "S": "8.5 x 11.0 x 0.5"
                    },
                    "PageCount": {
                        "N": "500"
                    },
                    "InPublication": {
                        "BOOL": true
                    },
                    "ProductCategory": {
                        "S": "Book"
                    }
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "102"
                    },
                    "Title": {
                        "S": "Book 102 Title"
                    },
                    "ISBN": {
                        "S": "222-2222222222"
                    },
                    "Authors": {
                        "L": [
                            {
                                "S": "Author1"
                            },
                            {
                                "S": "Author2"
                            }
                        ]
                    },
                    "Price": {
                        "N": "20"
                    },
                    "Dimensions": {
                        "S": "8.5 x 11.0 x 0.8"
                    },
```

```
                    "PageCount": {
                        "N": "600"
                    },
                    "InPublication": {
                        "BOOL": true
                    },
                    "ProductCategory": {
                        "S": "Book"
                    }
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "103"
                    },
                    "Title": {
                        "S": "Book 103 Title"
                    },
                    "ISBN": {
                        "S": "333-3333333333"
                    },
                    "Authors": {
                        "L": [
                            {
                                "S": "Author1"
                            },
                            {
                                "S": "Author2"
                            }
                        ]
                    },
                    "Price": {
                        "N": "2000"
                    },
                    "Dimensions": {
                        "S": "8.5 x 11.0 x 1.5"
                    },
                    "PageCount": {
                        "N": "600"
                    },
                    "InPublication": {
```

```
                    "BOOL": false
                },
                "ProductCategory": {
                    "S": "Book"
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "201"
                    },
                    "Title": {
                        "S": "18-Bike-201"
                    },
                    "Description": {
                        "S": "201 Description"
                    },
                    "BicycleType": {
                        "S": "Road"
                    },
                    "Brand": {
                        "S": "Mountain A"
                    },
                    "Price": {
                        "N": "100"
                    },
                    "Color": {
                        "L": [
                            {
                                "S": "Red"
                            },
                            {
                                "S": "Black"
                            }
                        ]
                    },
                    "ProductCategory": {
                        "S": "Bicycle"
                    }
                }
            }
```

```
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "202"
                    },
                    "Title": {

Creating example tables and uploading data in DynamoDB

This appendix provides code to both create the tables and add data programmatically.

Topics

- Creating example tables and uploading data using the AWS SDK for Java
- Creating example tables and uploading data using the AWS SDK for .NET

Creating example tables and uploading data using the AWS SDK for Java

The following Java code example creates tables and uploads data to the tables. For step-by-step instructions to run this code using Eclipse, see Java code examples.

```
package com.amazonaws.codesamples;

import java.text.SimpleDateFormat;
import java.util.ArrayList;
import java.util.Arrays;
import java.util.Date;
import java.util.HashSet;
import java.util.TimeZone;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.model.AttributeDefinition;
import com.amazonaws.services.dynamodbv2.model.CreateTableRequest;
import com.amazonaws.services.dynamodbv2.model.KeySchemaElement;
import com.amazonaws.services.dynamodbv2.model.KeyType;
import com.amazonaws.services.dynamodbv2.model.LocalSecondaryIndex;
import com.amazonaws.services.dynamodbv2.model.Projection;
import com.amazonaws.services.dynamodbv2.model.ProjectionType;

Creating example tables and uploading data using the AWS SDK for .NET

The following C# code example creates tables and uploads data to the tables. For step-by-step instructions to run this code in Visual Studio, see .NET code examples.

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
{
    class CreateTablesLoadData
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                //DeleteAllTables(client);
                DeleteTable("ProductCatalog");
                DeleteTable("Forum");
                DeleteTable("Thread");
                DeleteTable("Reply");

                // Create tables (using the AWS SDK for .NET low-level API).
                CreateTableProductCatalog();
                CreateTableForum();
```

```
            CreateTableThread(); // ForumTitle, Subject */

            var bicycle1 = new Document();
            bicycle1["Id"] = 201;
            bicycle1["Title"] = "18-Bike 201"; // size, followed by some title.
            bicycle1["Description"] = "201 description";
            bicycle1["BicycleType"] = "Road";
            bicycle1["Brand"] = "Brand-Company A"; // Trek, Specialized.
            bicycle1["Price"] = 100;
            bicycle1["Color"] = new List<string> { "Red", "Black" };
            bicycle1["ProductCategory"] = "Bike";
            productCatalogTable.PutItem(bicycle1);

            var bicycle2 = new Document();
            bicycle2["Id"] = 202;
            bicycle2["Title"] = "21-Bike 202Brand-Company A";
            bicycle2["Description"] = "202 description";
            bicycle2["BicycleType"] = "Road";
            bicycle2["Brand"] = "";
            bicycle2["Price"] = 200;
            bicycle2["Color"] = new List<string> { "Green", "Black" };
            bicycle2["ProductCategory"] = "Bicycle";
            productCatalogTable.PutItem(bicycle2);

            var bicycle3 = new Document();
            bicycle3["Id"] = 203;
            bicycle3["Title"] = "19-Bike 203";
            bicycle3["Description"] = "203 description";
            bicycle3["BicycleType"] = "Road";
            bicycle3["Brand"] = "Brand-Company B";
            bicycle3["Price"] = 300;
            bicycle3["Color"] = new List<string> { "Red", "Green", "Black" };
            bicycle3["ProductCategory"] = "Bike";
            productCatalogTable.PutItem(bicycle3);

            var bicycle4 = new Document();
```

```
            bicycle4["Id"] = 204;
            bicycle4["Title"] = "18-Bike 204";
            bicycle4["Description"] = "204 description";
            bicycle4["BicycleType"] = "Mountain";
            bicycle4["Brand"] = "Brand-Company B";
            bicycle4["Price"] = 400;
            bicycle4["Color"] = new List<string> { "Red" };
            bicycle4["ProductCategory"] = "Bike";
            productCatalogTable.PutItem(bicycle4);

            var bicycle5 = new Document();
            bicycle5["Id"] = 205;
            bicycle5["Title"] = "20-Title 205";
            bicycle4["Description"] = "205 description";
            bicycle5["BicycleType"] = "Hybrid";
            bicycle5["Brand"] = "Brand-Company C";
            bicycle5["Price"] = 500;
            bicycle5["Color"] = new List<string> { "Red", "Black" };
            bicycle5["ProductCategory"] = "Bike";
            productCatalogTable.PutItem(bicycle5);
        }

        private static void LoadSampleForums()
        {

 attribute.
            thread2Reply2["ReplyDateTime"] = DateTime.UtcNow.Subtract(new TimeSpan(1,
 0, 0, 0)); // Range attribute.
            thread2Reply2["Message"] = "DynamoDB Thread 2 Reply 2 text";
            thread2Reply2["PostedBy"] = "User A";

            replyTable.PutItem(thread2Reply2);
        }
    }
}
```

DynamoDB example application using the AWS SDK for Python (Boto): Tic-tac-toe

The Tic-Tac-Toe game is an example web application built on Amazon DynamoDB. The application uses the AWS SDK for Python (Boto) to make the necessary DynamoDB calls to store game data in a DynamoDB table, and the Python web framework Flask to illustrate end-to-end application development in DynamoDB, including how to model data. It also demonstrates best practices when it comes to modeling data in DynamoDB, including the table you create for the game application, the primary key you define, additional indexes you need based on your query requirements, and the use of concatenated value attributes.

You play the Tic-Tac-Toe application on the web as follows:

1. You log in to the application home page.
2. You then invite another user to play the game as your opponent.

Until another user accepts your invitation, the game status remains as `PENDING`. After an opponent accepts the invite, the game status changes to `IN_PROGRESS`.

3. The game begins after the opponent logs in and accepts the invite.
4. The application stores all game moves and status information in a DynamoDB table.
5. The game ends with a win or a draw, which sets the game status to `FINISHED`.

The end-to-end application building exercise is described in steps:

- **Step 1: Deploy and test locally** – In this section, you download, deploy, and test the application on your local computer. You will create the required tables in the downloadable version of DynamoDB.
- **Step 2: Examine the data model and implementation details** – This section first describes in detail the data model, including the indexes and the use of the concatenated value attribute. Then the section explains how the application works.
- **Step 3: Deploy in production using the DynamoDB service** – This section focuses on deployment considerations in production. In this step, you create a table using the Amazon DynamoDB service and deploy the application using AWS Elastic Beanstalk. When you have the application in production, you also grant appropriate permissions so the application can access the DynamoDB table. The instructions in this section walk you through the end-to-end production deployment.
- **Step 4: Clean up resources** – This section highlights areas that are not covered by this example. The section also provides steps for you to remove the AWS resources you created in the preceding steps so that you avoid incurring any charges.

Step 1: Deploy and test locally

Topics

- 1.1: Download and install the required packages
- 1.2: Test the game application

In this step you download, deploy, and test the Tic-Tac-Toe game application on your local computer. Instead of using the Amazon DynamoDB web service, you will download DynamoDB to your computer, and create the required table there.

1.1: Download and install the required packages

You will need the following to test this application locally:

- Python
- Flask (a microframework for Python)
- AWS SDK for Python (Boto)
- DynamoDB running on your computer
- Git

To get these tools, do the following:

1. Install Python. For step-by-step instructions, see Download Python.

   The Tic-Tac-Toe application has been tested using Python version 2.7.
2. Install Flask and AWS SDK for Python (Boto) using the Python Package Installer (PIP):
   - Install PIP.

     For instructions, see Install PIP. On the installation page, choose the **get-pip.py** link, and then save the file. Then open a command terminal as an administrator, and enter the following at the command prompt.

     ```
     python.exe get-pip.py
     ```

     On Linux, you don't specify the `.exe` extension. You only specify `python get-pip.py`.
   - Using PIP, install the Flask and Boto packages using the following code.

     ```
     pip install Flask
     pip install boto
     pip install configparser
     ```
3. Download DynamoDB to your computer. For instructions on how to run it, see Setting up DynamoDB local (downloadable version).
4. Download the Tic-Tac-Toe application:

   a. Install Git. For instructions, see git downloads.

   b. Run the following code to download the application.

```
git clone https://github.com/awslabs/dynamodb-tictactoe-example-app.git
```

1.2: Test the game application

To test the Tic-Tac-Toe application, you need to run DynamoDB locally on your computer.

To run the tic-tac-toe application

1. Start DynamoDB.
2. Start the web server for the Tic-Tac-Toe application.

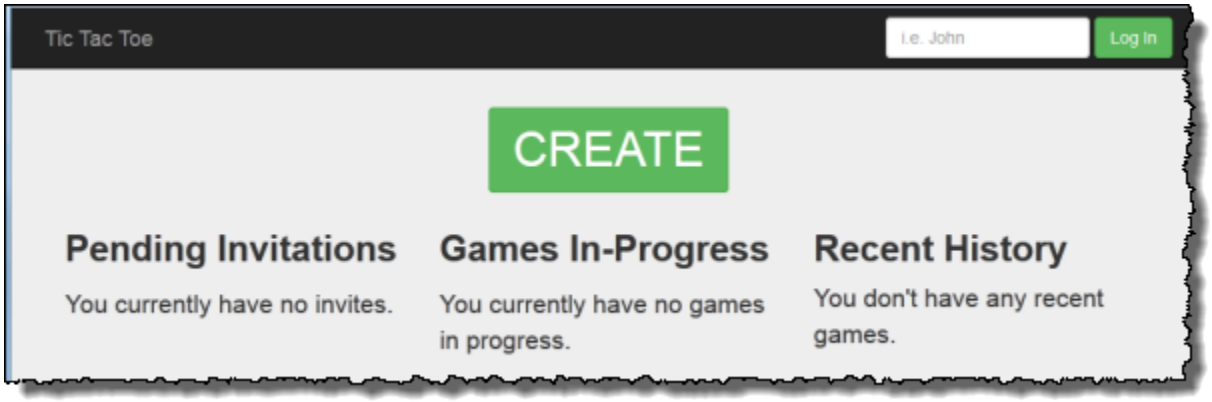
   To do so, open a command terminal, navigate to the folder where you downloaded the Tic-Tac-Toe application, and run the application locally using the following code.

   ```
   python.exe application.py --mode local --serverPort 5000 --port 8000
   ```

   On Linux, you don't specify the `.exe` extension.
3. Open your web browser, and enter the following.

   ```
   http://localhost:5000/
   ```

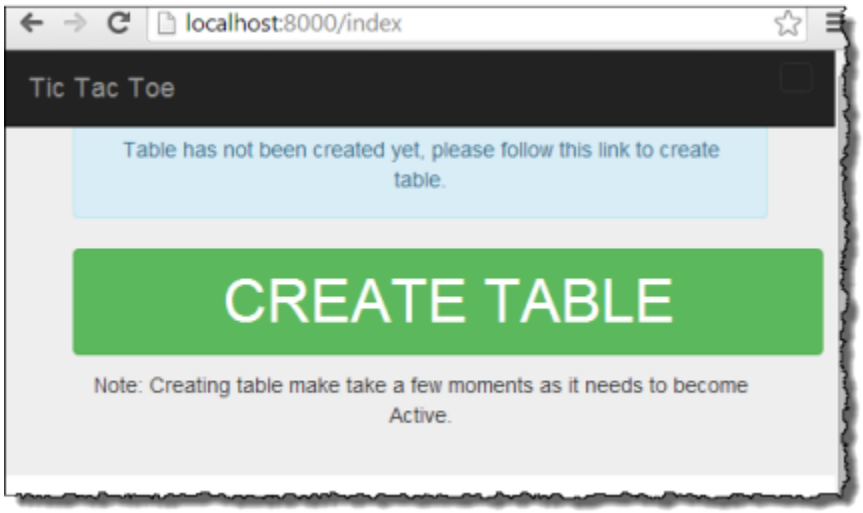
   The browser shows the home page.



4. Enter **`user1`** in the **Log in** box to log in as user1.

> **Note**
>
> This example application does not perform any user authentication. The user ID is only used to identify players. If two players log in with the same alias, the application works as if you are playing in two different browsers.

5. If this is your first time playing the game, a page appears requesting you to create the required table (`Games`) in DynamoDB. Choose **CREATE TABLE**.



6. Choose **CREATE** to create the first tic-tac-toe game.
7. Enter **`user2`** in the **Choose an Opponent** box, and choose **Create Game!**

   Doing this creates the game by adding an item in the `Games` table. It sets the game status to `PENDING`.

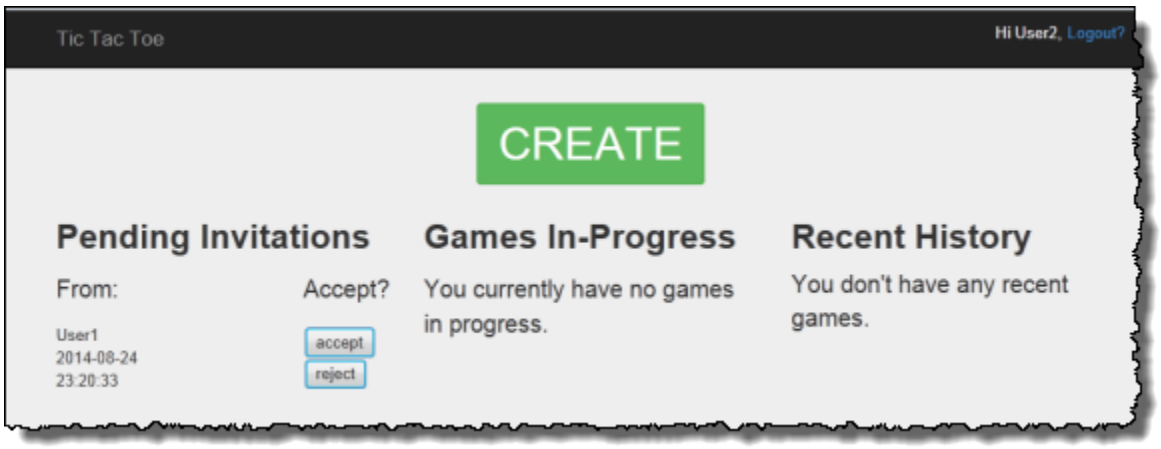
8. Open another browser window, and enter the following.

```
http://localhost:5000/
```

The browser passes information through cookies, so you should use incognito mode or private browsing so that your cookies don't carry over.

9. Log in as user2.

   A page appears that shows a pending invitation from user1.



10. Choose **accept** to accept the invitation.

   The game page appears with an empty tic-tac-toe grid. The page also shows relevant game information such as the game ID, whose turn it is, and game status.

11. Play the game.

For each user move, the web service sends a request to DynamoDB to conditionally update the game item in the `Games` table. For example, the conditions make sure that the move is valid, the square that the user chose is available, and that it was the turn of the user who made the move. For a valid move, the update operation adds a new attribute corresponding to the selection on the board. The update operation also sets the value of the existing attribute to the user who can make the next move.

On the game page, the application makes asynchronous JavaScript calls every second, for up to 5 minutes, to check if the game state in DynamoDB has changed. If it has, the application updates the page with new information. After 5 minutes, the application stops making the requests, and you need to refresh the page to get updated information.

Step 2: Examine the data model and implementation details

Topics

- 2.1: Basic data model
- 2.2: Application in action (code walkthrough)

2.1: Basic data model

This example application highlights the following DynamoDB data model concepts:

- **Table** – In DynamoDB, a table is a collection of items (that is, records), and each item is a collection of name-value pairs called attributes.

  In this Tic-Tac-Toe example, the application stores all game data in a table, `Games`. The application creates one item in the table per game and stores all game data as attributes. A tic-tac-toe game can have up to nine moves. Because DynamoDB tables do not have a schema in cases where only the primary key is the required attribute, the application can store varying number of attributes per game item.

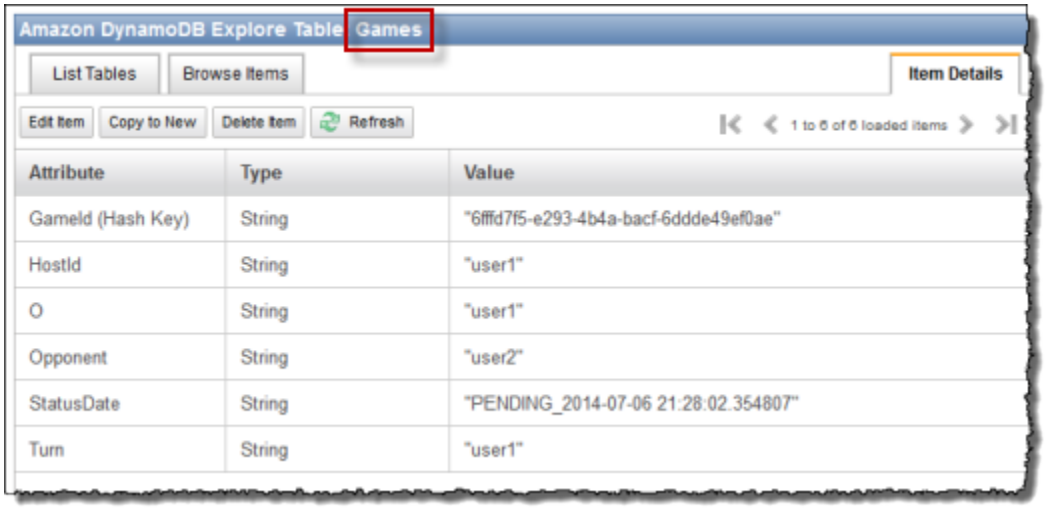
  The `Games` table has a simple primary key made of one attribute, `GameId`, of string type. The application assigns a unique ID to each game. For more information on DynamoDB primary keys, see Primary key.

  When a user initiates a tic-tac-toe game by inviting another user to play, the application creates a new item in the `Games` table with attributes storing game metadata, such as the following:

  - `HostId`, the user who initiated the game.

- `Opponent`, the user who was invited to play.
- The user whose turn it is to play. The user who initiated the game plays first.
- The user who uses the **O** symbol on the board. The user who initiates the games uses the **O** symbol.

In addition, the application creates a `StatusDate` concatenated attribute, marking the initial game state as `PENDING`. The following screenshot shows an example item as it appears in the DynamoDB console:

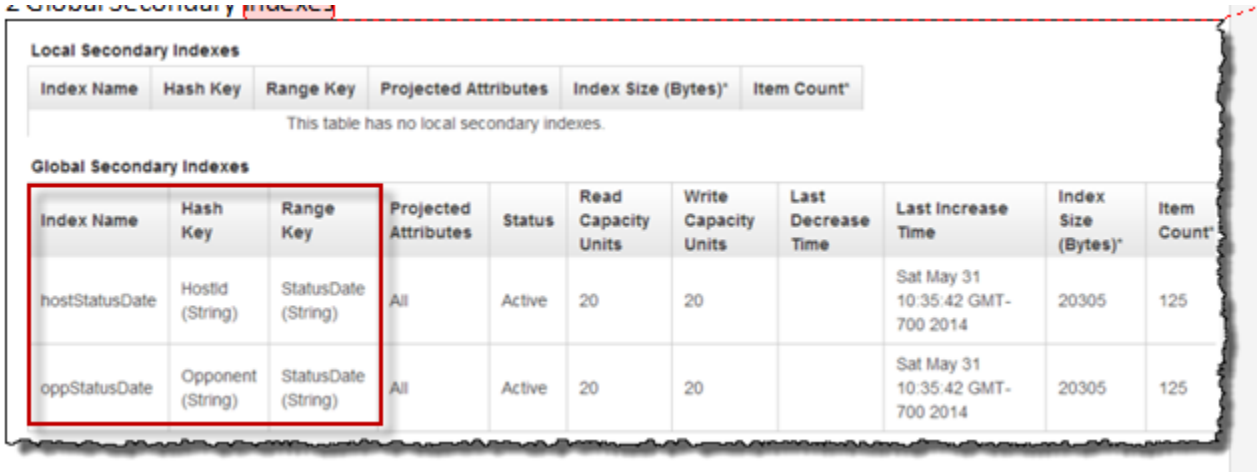


As the game progresses, the application adds one attribute to the table for each game move. The attribute name is the board position, for example `TopLeft` or `BottomRight`. For example, a move might have a `TopLeft` attribute with the value 0, a `TopRight` attribute with the value 0, and a `BottomRight` attribute with the value X. The attribute value is either 0 or X, depending on which user made the move. For example, consider the following board.

- **Concatenated value attributes** – The `StatusDate` attribute illustrates a concatenated value attribute. In this approach, instead of creating separate attributes to store game status (`PENDING`, `IN_PROGRESS`, and `FINISHED`) and date (when the last move was made), you combine them as single attribute, for example `IN_PROGRESS_2014-04-30 10:20:32`.

  The application then uses the `StatusDate` attribute in creating secondary indexes by specifying `StatusDate` as a sort key for the index. The benefit of using the `StatusDate` concatenated value attribute is further illustrated in the indexes discussed next.

- **Global secondary indexes** – You can use the table's primary key, `GameId`, to efficiently query the table to find a game item. To query the table on attributes other than the primary key attributes, DynamoDB supports the creation of secondary indexes. In this example application, you build the following two secondary indexes:



Local Secondary Indexes

Index Name	Hash Key	Range Key	Projected Attributes	Index Size (Bytes)*	Item Count*

This table has no local secondary indexes.

Global Secondary Indexes

Index Name	Hash Key	Range Key	Projected Attributes	Status	Read Capacity Units	Write Capacity Units	Last Decrease Time	Last Increase Time	Index Size (Bytes)*	Item Count*
hostStatusDate	HostId (String)	StatusDate (String)	All	Active	20	20		Sat May 31 10:35:42 GMT-700 2014	20305	125
oppStatusDate	Opponent (String)	StatusDate (String)	All	Active	20	20		Sat May 31 10:35:42 GMT-700 2014	20305	125

  - **HostId-StatusDate-index**. This index has `HostId` as a partition key and `StatusDate` as a sort key. You can use this index to query on `HostId`, for example to find games hosted by a particular user.
  - **OpponentId-StatusDate-index**. This index has `OpponentId` as a partition key and `StatusDate` as a sort key. You can use this index to query on `Opponent`, for example to find games where a particular user is the opponent.

  These indexes are called global secondary indexes because the partition key in these indexes is not the same the partition key (`GameId`), used in the primary key of the table.

  Note that both the indexes specify `StatusDate` as a sort key. Doing this enables the following:

  - You can query using the `BEGINS_WITH` comparison operator. For example, you can find all games with the `IN_PROGRESS` attribute hosted by a particular user. In this case, the `BEGINS_WITH` operator checks for the `StatusDate` value that begins with `IN_PROGRESS`.

- DynamoDB stores the items in the index in sorted order, by sort key value. So if all status prefixes are the same (for example, `IN_PROGRESS`), the ISO format used for the date part will have items sorted from oldest to the newest. This approach enables certain queries to be performed efficiently, for example the following:
  - Retrieve up to 10 of the most recent `IN_PROGRESS` games hosted by the user who is logged in. For this query, you specify the `HostId-StatusDate-index` index.
  - Retrieve up to 10 of the most recent `IN_PROGRESS` games where the user logged in is the opponent. For this query, you specify the `OpponentId-StatusDate-index` index.

For more information about secondary indexes, see Improving data access with secondary indexes in DynamoDB.

2.2: Application in action (code walkthrough)

This application has two main pages:

- **Home page** – This page provides the user a simple login, a **CREATE** button to create a new tic-tac-toe game, a list of games in progress, game history, and any active pending game invitations.

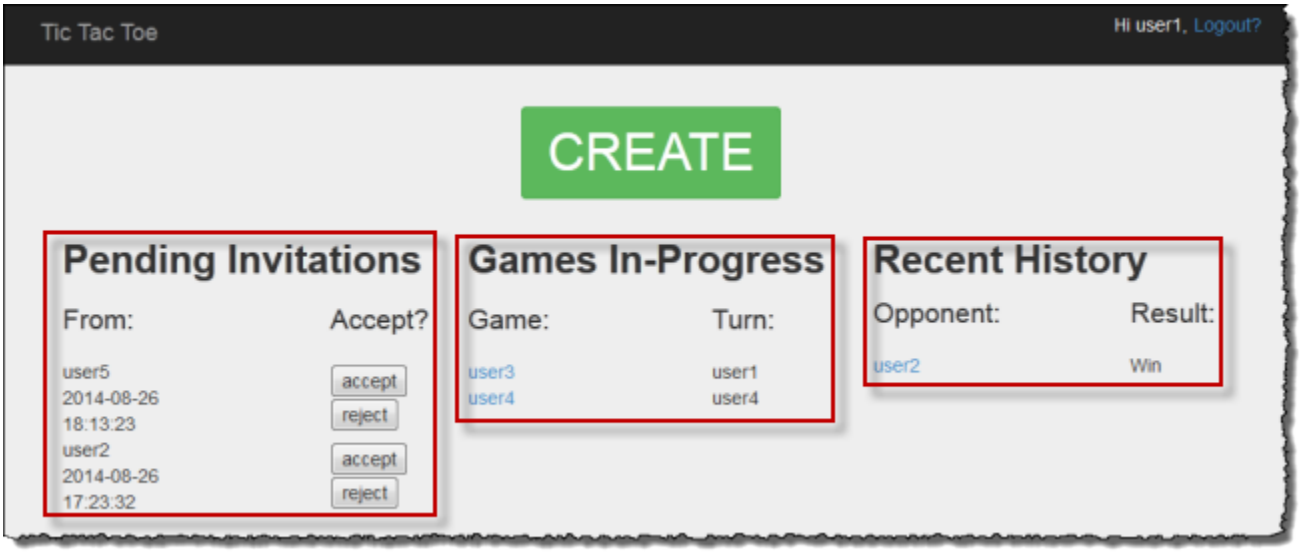
  The home page is not refreshed automatically; you must refresh the page to refresh the lists.
- **Game page** – This page shows the tic-tac-toe grid where users play.

  The application updates the game page automatically every second. The JavaScript in your browser calls the Python web server every second to query the Games table whether the game items in the table have changed. If they have, JavaScript triggers a page refresh so that the user sees the updated board.

Let us see in detail how the application works.

Home page

After the user logs in, the application displays the following three lists of information.



- **Invitations** – This list shows up to the 10 most recent invitations from others that are pending acceptance by the user who is logged in. In the preceding screenshot, user1 has invitations from user5 and user2 pending.
- **Games in-progress** – This list shows up to the 10 most recent games that are in progress. These are games that the user is actively playing, which have the status `IN_PROGRESS`. In the screenshot, user1 is actively playing a tic-tac-toe game with user3 and user4.
- **Recent history** – This list shows up to the 10 most recent games that the user finished, which have the status `FINISHED`. In game shown in the screenshot, user1 has previously played with user2. For each completed game, the list shows the game result.

In the code, the `index` function (in `application.py`) makes the following three calls to retrieve game status information:

```
inviteGames     = controller.getGameInvites(session["username"])
inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
finishedGames   = controller.getGamesWithStatus(session["username"], "FINISHED")
```

Each of these calls returns a list of items from DynamoDB that are wrapped by the `Game` objects. It is easy to extract data from these objects in the view. The index function passes these object lists to the view to render the HTML.

```
return render_template("index.html",
                       user=session["username"],
                       invites=inviteGames,
```

```
                        inprogress=inProgressGames,
                        finished=finishedGames)
```

The Tic-Tac-Toe application defines the `Game` class primarily to store game data retrieved from DynamoDB. These functions return lists of `Game` objects that enable you to isolate the rest of the application from code related to Amazon DynamoDB items. Thus, these functions help you decouple your application code from the details of the data store layer.

The architectural pattern described here is also referred as the model-view-controller (MVC) UI pattern. In this case, the `Game` object instances (representing data) are the model, and the HTML page is the view. The controller is divided into two files. The `application.py` file has the controller logic for the Flask framework, and the business logic is isolated in the `gameController.py` file. That is, the application stores everything that has to do with DynamoDB SDK in its own separate file in the `dynamodb` folder.

Let us review the three functions and how they query the Games table using global secondary indexes to retrieve relevant data.

Using getGameInvites to get the list of pending game invitations

The `getGameInvites` function retrieves the list of the 10 most recent pending invitations. These games have been created by users, but the opponents have not accepted the game invitations. For these games, the status remains `PENDING` until the opponent accepts the invite. If the opponent declines the invite, the application removes the corresponding item from the table.

The function specifies the query as follows:

- It specifies the `OpponentId-StatusDate-index` index to use with the following index key values and comparison operators:
  - The partition key is `OpponentId` and takes the index key *`user ID`*.
  - The sort key is `StatusDate` and takes the comparison operator and index key value `beginswith="PENDING_"`.

  You use the `OpponentId-StatusDate-index` index to retrieve games to which the logged-in user is invited—that is, where the logged-in user is the opponent.
- The query limits the result to 10 items.

```
gameInvitesIndex = self.cm.getGamesTable().query(
```

```
                                        Opponent__eq=user,
                                        StatusDate__beginswith="PENDING_",
                                        index="OpponentId-StatusDate-index",
                                        limit=10)
```

In the index, for each `OpponentId` (the partition key) DynamoDB keeps items sorted by `StatusDate` (the sort key). Therefore, the games that the query returns will be the 10 most recent games.

Using getGamesWithStatus to get the list of games with a specific status

After an opponent accepts a game invitation, the game status changes to `IN_PROGRESS`. After the game completes, the status changes to `FINISHED`.

Queries to find games that are either in progress or finished are the same except for the different status value. Therefore, the application defines the `getGamesWithStatus` function, which takes the status value as a parameter.

```
inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
finishedGames   = controller.getGamesWithStatus(session["username"], "FINISHED")
```

The following section discusses in-progress games, but the same description also applies to finished games.

A list of in-progress games for a given user includes both the following:

- In-progress games hosted by the user
- In-progress games where the user is the opponent

The `getGamesWithStatus` function runs the following two queries, each time using the appropriate secondary index.

- The function queries the `Games` table using the `HostId-StatusDate-index` index. For the index, the query specifies primary key values—both the partition key (`HostId`) and sort key (`StatusDate`) values, along with comparison operators.

  ```
  hostGamesInProgress = self.cm.getGamesTable ().query(HostId__eq=user,
                                                       StatusDate__beginswith=status,
                                                       index="HostId-StatusDate-index",
                                                       limit=10)
  ```

Note the Python syntax for comparison operators:

- `HostId__eq=user` specifies the equality comparison operator.
- `StatusDate__beginswith=status` specifies the `BEGINS_WITH` comparison operator.

- The function queries the `Games` table using the `OpponentId-StatusDate-index` index.

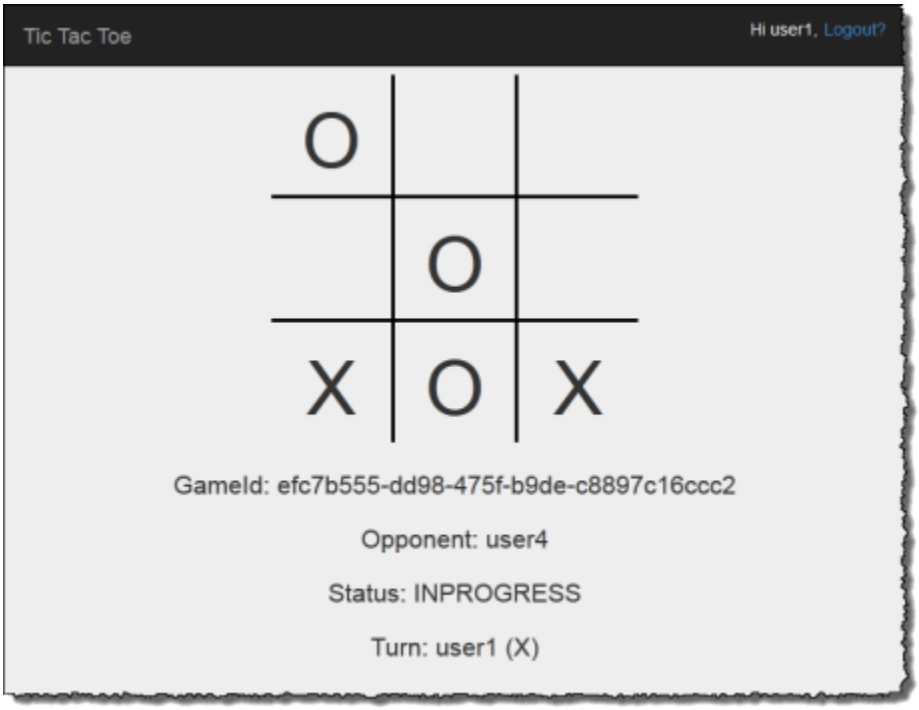
```
oppGamesInProgress = self.cm.getGamesTable().query(Opponent__eq=user,
                                                   StatusDate__beginswith=status,
                                                   index="OpponentId-StatusDate-index",
                                                   limit=10)
```

- The function then combines the two lists, sorts, and for the first 0 to 10 items creates a list of the `Game` objects and returns the list to the calling function (that is, the index).

```
games = self.mergeQueries(hostGamesInProgress,
                          oppGamesInProgress)
return games
```

Game page

The game page is where the user plays tic-tac-toe games. It shows the game grid along with game-relevant information. The following screenshot shows an example game in progress:



The application displays the game page in the following situations:

- The user creates a game inviting another user to play.

  In this case, the page shows the user as host and the game status as `PENDING`, waiting for the opponent to accept.
- The user accepts one of the pending invitations on the home page.

  In this case, the page shows the user as the opponent and game status as `IN_PROGRESS`.

A user selection on the board generates a form `POST` request to the application. That is, Flask calls the `selectSquare` function (in `application.py`) with the HTML form data. This function, in turn, calls the `updateBoardAndTurn` function (in `gameController.py`) to update the game item as follows:

- It adds a new attribute specific to the move.
- It updates the `Turn` attribute value to the user whose turn is next.

```
controller.updateBoardAndTurn(item, value, session["username"])
```

The function returns true if the item update was successful; otherwise, it returns false. Note the following about the `updateBoardAndTurn` function:

- The function calls the `update_item` function of the SDK for Python (Boto) to make a finite set of updates to an existing item. The function maps to the `UpdateItem` operation in DynamoDB. For more information, see UpdateItem.

  > **Note**
  >
  > The difference between the `UpdateItem` and `PutItem` operations is that `PutItem` replaces the entire item. For more information, see PutItem.

For the `update_item` call, the code identifies the following:

- The primary key of the `Games` table (that is, `ItemId`).

```
key = { "GameId" : { "S" : gameId } }
```

- The new attribute to add, specific to the current user move, and its value (for example, `TopLeft="X"`).

```
attributeUpdates = {
    position : {
        "Action" : "PUT",
        "Value" : { "S" : representation }
    }
}
```

- Conditions that must be true for the update to take place:
  - The game must be in progress. That is, the `StatusDate` attribute value must begin with `IN_PROGRESS`.
  - The current turn must be a valid user turn as specified by the `Turn` attribute.
  - The square that the user chose must be available. That is, the attribute corresponding to the square must not exist.

```
expectations = {"StatusDate" : {"AttributeValueList": [{"S" : "IN_PROGRESS_"}],
    "ComparisonOperator": "BEGINS_WITH"},
    "Turn" : {"Value" : {"S" : current_player}},
    position : {"Exists" : False}}
```

Now the function calls `update_item` to update the item.

```
self.cm.db.update_item("Games", key=key,
    attribute_updates=attributeUpdates,
    expected=expectations)
```

After the function returns, the `selectSquare` function calls redirect, as shown in the following example.

```
redirect("/game="+gameId)
```

This call causes the browser to refresh. As part of this refresh, the application checks to see if the game has ended in a win or draw. If it has, the application updates the game item accordingly.

Step 3: Deploy in production using the DynamoDB service

Topics

- 3.1: Create an IAM role for Amazon EC2
- 3.2: Create the games table in Amazon DynamoDB
- 3.3: Bundle and deploy the tic-tac-toe application code
- 3.4: Set up the AWS Elastic Beanstalk environment

In the preceding sections, you deployed and tested the Tic-Tac-Toe application locally on your computer using DynamoDB local. Now, you deploy the application in production as follows:

- Deploy the application using AWS Elastic Beanstalk, an easy-to-use service for deploying and scaling web applications and services. For more information, see Deploying a flask application to AWS Elastic Beanstalk.

  Elastic Beanstalk launches one or more Amazon Elastic Compute Cloud (Amazon EC2) instances, which you configure through Elastic Beanstalk, on which your Tic-Tac-Toe application will run.
- Using the Amazon DynamoDB service, create a `Games` table that exists on AWS rather than locally on your computer.

In addition, you also have to configure permissions. Any AWS resources you create, such as the `Games` table in DynamoDB, are private by default. Only the resource owner, that is the AWS account that created the `Games` table, can access this table. Thus, by default your Tic-Tac-Toe application cannot update the `Games` table.

To grant necessary permissions, you create an AWS Identity and Access Management (IAM) role and grant this role permissions to access the `Games` table. Your Amazon EC2 instance first assumes this role. In response, AWS returns temporary security credentials that the Amazon EC2 instance can use to update the `Games` table on behalf of the Tic-Tac-Toe application. When you configure your Elastic Beanstalk application, you specify the IAM role that the Amazon EC2 instance or instances can assume. For more information about IAM roles, see IAM roles for amazon EC2 in the *Amazon EC2 User Guide.*

> **Note**
>
> Before you create Amazon EC2 instances for the Tic-Tac-Toe application, you must first decide the AWS Region where you want Elastic Beanstalk to create the instances. After you create the Elastic Beanstalk application, you provide the same Region name and endpoint in a configuration file. The Tic-Tac-Toe application uses information in this file to create the `Games` table and send subsequent requests in a specific AWS Region. Both the DynamoDB `Games` table and the Amazon EC2 instances that Elastic Beanstalk launches must be in the same Region. For a list of available Regions, see Amazon DynamoDB in the *Amazon Web Services General Reference*.

In summary, you do the following to deploy the Tic-Tac-Toe application in production:

1. Create an IAM role using the IAM service. You attach a policy to this role granting permissions for DynamoDB actions to access the `Games` table.
2. Bundle the Tic-Tac-Toe application code and a configuration file, and create a `.zip` file. You use this `.zip` file to give the Tic-Tac-Toe application code to Elastic Beanstalk to put on your servers. For more information about creating a bundle, see Creating an application source bundle in the *AWS Elastic Beanstalk Developer Guide*.

   In the configuration file (`beanstalk.config`), you provide AWS Region and endpoint information. The Tic-Tac-Toe application uses this information to determine which DynamoDB Region to talk to.
3. Set up the Elastic Beanstalk environment. Elastic Beanstalk launches an Amazon EC2 instance or instances and deploys your Tic-Tac-Toe application bundle on them. After the Elastic Beanstalk environment is ready, you provide the configuration file name by adding the `CONFIG_FILE` environment variable.
4. Create the DynamoDB table. Using the Amazon DynamoDB service, you create the `Games` table on AWS, rather than locally on your computer. Remember, this table has a simple primary key made of the `GameId` partition key of string type.
5. Test the game in production.

3.1: Create an IAM role for Amazon EC2

Creating an IAM role of the **Amazon EC2** type allows the Amazon EC2 instance that is running your Tic-Tac-Toe application to assume the correct role and make application requests to access the `Games` table. When creating the role, choose the **Custom Policy** option and copy and paste the following policy.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Action":[
            "dynamodb:ListTables"
         ],
         "Effect":"Allow",
         "Resource":"*"
      },
      {
         "Action":[
            "dynamodb:*"
         ],
         "Effect":"Allow",
         "Resource":[
            "arn:aws:dynamodb:us-west-2:922852403271:table/Games",
            "arn:aws:dynamodb:us-west-2:922852403271:table/Games/index/*"
         ]
      }
   ]
}
```

For further instructions, see Creating a role for an AWS service (AWS Management Console) in the *IAM User Guide*.

3.2: Create the games table in Amazon DynamoDB

The `Games` table in DynamoDB stores game data. If the table does not exist, the application creates the table for you. In this case, let the application create the `Games` table.

3.3: Bundle and deploy the tic-tac-toe application code

If you followed this example's steps, then you already have the downloaded the Tic-Tac-Toe application. If not, download the application and extract all the files to a folder on your local computer. For instructions, see Step 1: Deploy and test locally.

After you extract all files, you will have a `code` folder. To hand off this folder to Elastic Beanstalk, you bundle the contents of this folder as a `.zip` file. First, you add a configuration file to that folder. Your application uses the Region and endpoint information to create a DynamoDB table in the specified Region and make subsequent table operation requests using the specified endpoint.

1. Switch to the folder where you downloaded the Tic-Tac-Toe application.
2. In the root folder of the application, create a text file named `beanstalk.config` with the following content.

   ```
   [dynamodb]
   region=<AWS region>
   endpoint=<DynamoDB endpoint>
   ```

   For example, you might use the following content.

   ```
   [dynamodb]
   region=us-west-2
   endpoint=dynamodb.us-west-2.amazonaws.com
   ```

   For a list of available Regions, see Amazon DynamoDB in the *Amazon Web Services General Reference.*

   > **Important**
   >
   > The Region specified in the configuration file is the location where the Tic-Tac-Toe application creates the `Games` table in DynamoDB. You must create the Elastic Beanstalk application discussed in the next section in the same Region.

Note

When you create your Elastic Beanstalk application, you request to launch an environment where you can choose the environment type. To test the Tic-Tac-Toe example application, you can choose the **Single Instance** environment type, skip the following, and go to the next step.
However, the **Load balancing, autoscaling** environment type provides a highly available and scalable environment, something you should consider when you create and deploy other applications. If you choose this environment type, you also need to generate a UUID and add it to the configuration file, as shown following.

```
[dynamodb]
region=us-west-2
endpoint=dynamodb.us-west-2.amazonaws.com
[flask]
secret_key= 284e784d-1a25-4a19-92bf-8eeb7a9example
```

In client-server communication, when the server sends a response, for security's sake the server sends a signed cookie that the client sends back to the server in the next request. When there is only one server, the server can locally generate an encryption key when it starts. When there are many servers, they all need to know the same encryption key; otherwise, they won't be able to read cookies set by the peer servers. By adding `secret_key` to the configuration file, you tell all servers to use this encryption key.

3. Zip the content of the root folder of the application (which includes the `beanstalk.config` file)—for example, `TicTacToe.zip`.
4. Upload the `.zip` file to an Amazon Simple Storage Service (Amazon S3) bucket. In the next section, you provide this `.zip` file to Elastic Beanstalk to upload on the server or servers.

   For instructions on how to upload to an Amazon S3 bucket, see Create a bucket and Add an object to a bucket in the *Amazon Simple Storage Service User Guide.*

3.4: Set up the AWS Elastic Beanstalk environment

In this step, you create an Elastic Beanstalk application, which is a collection of components including environments. For this example, you launch one Amazon EC2 instance to deploy and run your Tic-Tac-Toe application.

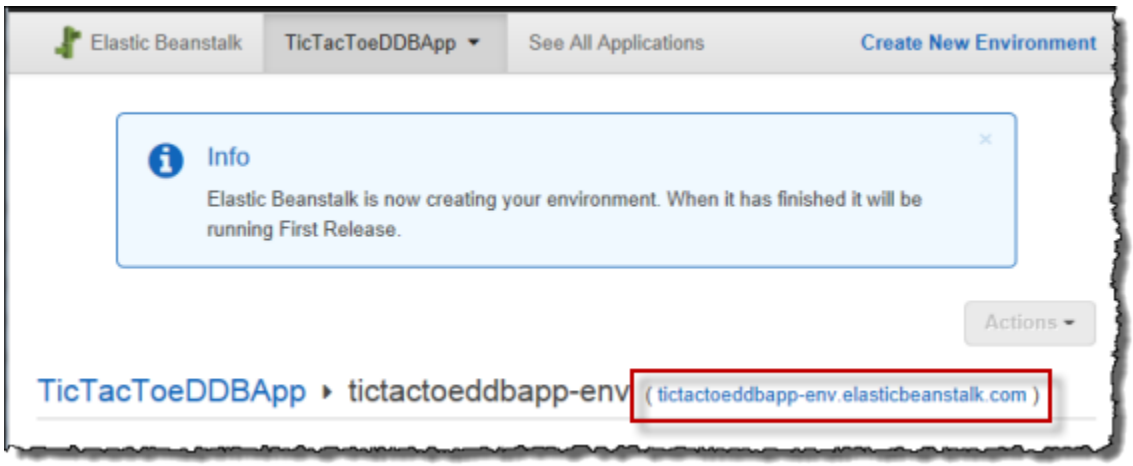
1. Enter the following custom URL to set up an Elastic Beanstalk console to set up the environment.

   ```
   https://console.aws.amazon.com/elasticbeanstalk/?region=<AWS-Region>#/
   newApplication
   ?applicationName=TicTacToeyour-name
   &solutionStackName=Python
   &sourceBundleUrl=https://s3.amazonaws.com/<bucket-name>/TicTacToe.zip
   &environmentType=SingleInstance
   &instanceType=t1.micro
   ```

   For more information about custom URLs, see Constructing a Launch Now URL in the *AWS Elastic Beanstalk Developer Guide.* For the URL, note the following:

   - You must provide an AWS Region name (the same as the one you provided in the configuration file), an Amazon S3 bucket name, and the object name.
   - For testing, the URL requests the **SingleInstance** environment type, and `t1.micro` as the instance type.
   - The application name must be unique. Thus, in the preceding URL, we suggest you prepend your name to the `applicationName`.

   Doing this opens the Elastic Beanstalk console. In some cases, you might need to sign in.
2. In the Elastic Beanstalk console, choose **Review and Launch**, and then choose **Launch**.
3. Note the URL for future reference. This URL opens your Tic-Tac-Toe application home page.



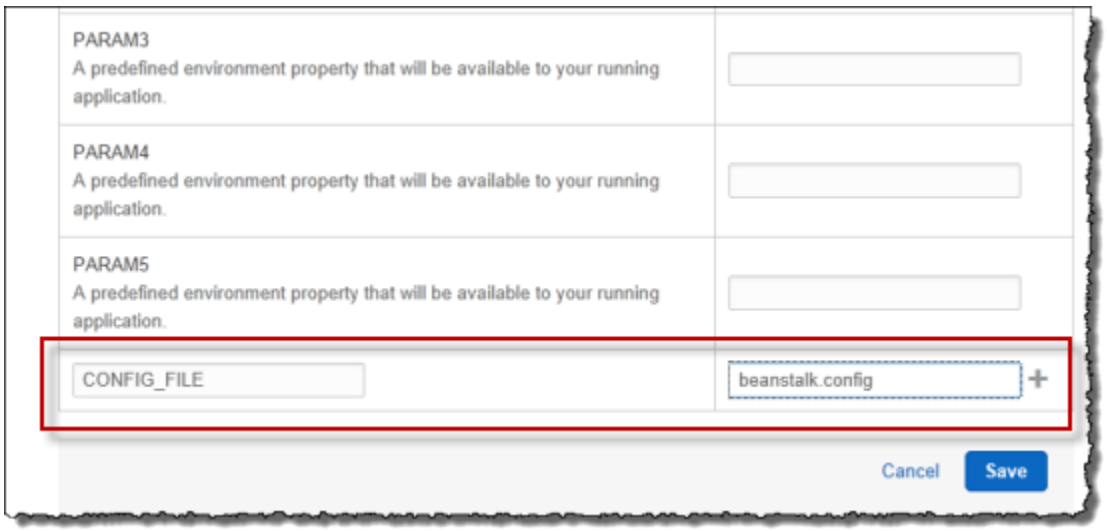
4. Configure the Tic-Tac-Toe application so it knows the location of the configuration file.

   After Elastic Beanstalk creates the application, choose **Configuration**.

   a. Choose the gear icon next to **Software Configuration**, as shown in the following screenshot.

   b. At the end of the **Environment Properties** section, enter **`CONFIG_FILE`** and its value **`beanstalk.config`**, and then choose **Save**.

      It might take a few minutes for this environment update to complete.

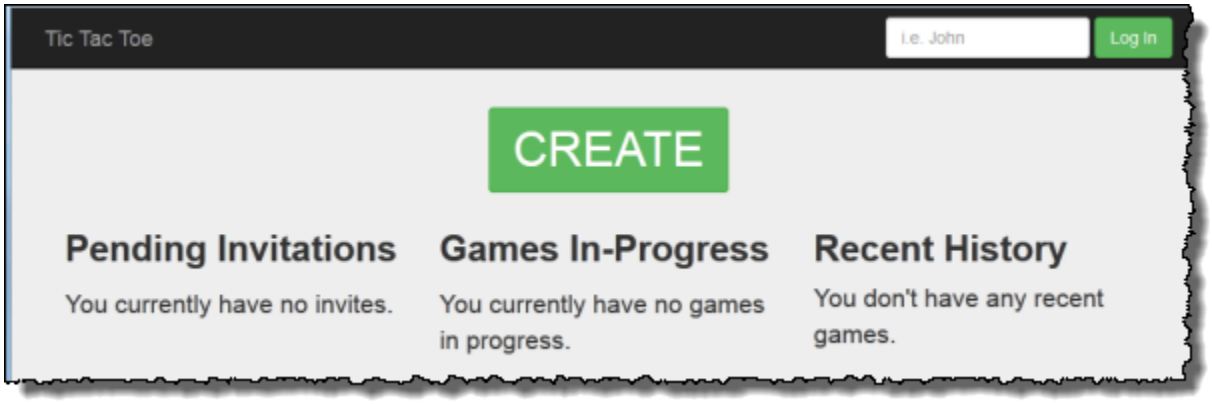


After the update completes, you can play the game.

5. In the browser, enter the URL you copied in the previous step, as shown in the following example.

```
http://<pen-name>.elasticbeanstalk.com
```

Doing this opens the application home page.



6. Log in as testuser1, and choose **CREATE** to start a new tic-tac-toe game.
7. Enter **`testuser2`** in the **Choose an Opponent** box.

8. Open another browser window.

   Make sure that you clear all cookies in your browser window so you won't be logged in as same user.

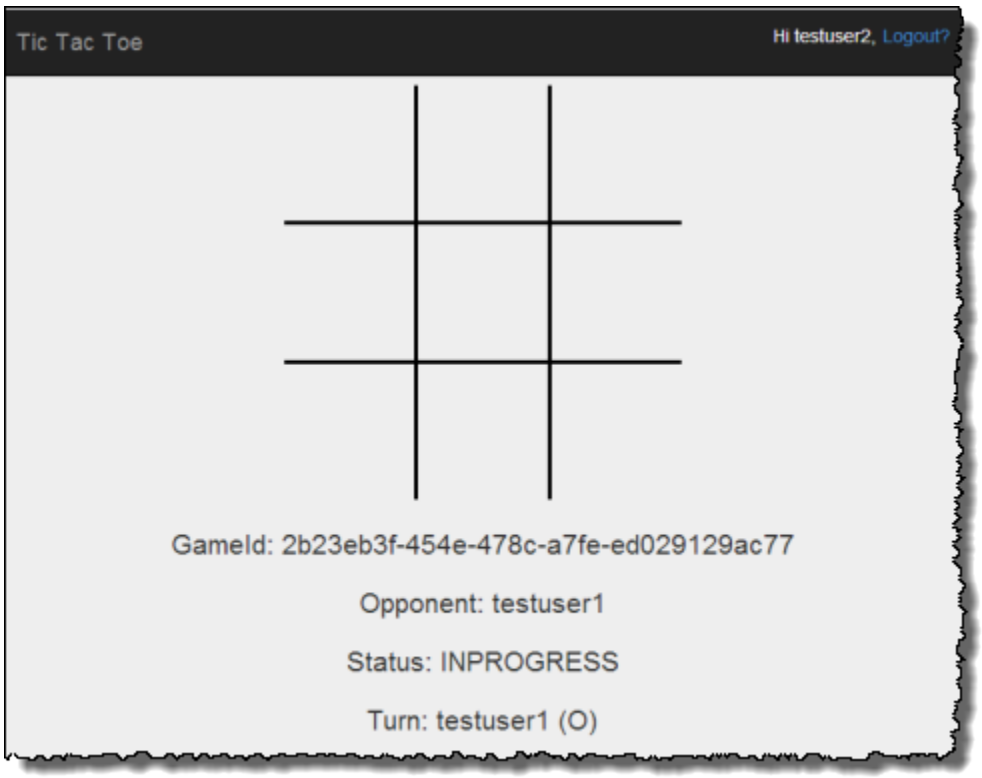
9. Enter the same URL to open the application home page, as shown in the following example.

   ```
   http://<env-name>.elasticbeanstalk.com
   ```

10. Log in as testuser2.

11. For the invitation from testuser1 in the list of pending invitations, choose **accept**.

12. Now the game page appears.



Both testuser1 and testuser2 can play the game. For each move, the application saves the move in the corresponding item in the `Games` table.

Step 4: Clean up resources

Now you have completed the Tic-Tac-Toe application deployment and testing. The application covers end-to-end web application development on Amazon DynamoDB, except for user authentication. The application uses the login information on the home page only to add a player name when creating a game. In a production application, you would add the necessary code to perform user login and authentication.

If you are done testing, you can remove the resources you created to test the Tic-Tac-Toe application to avoid incurring any charges.

To remove the resources you created

1. Remove the `Games` table that you created in DynamoDB.
2. Terminate the Elastic Beanstalk environment to free up the Amazon EC2 instances.
3. Delete the IAM role that you created.

4. Remove the object that you created in Amazon S3.

Reserved words in DynamoDB

The following keywords are reserved for use by DynamoDB. Don't use any of these words as attribute names in expressions. This list isn't case-sensitive.

If you need to write an expression containing an attribute name that conflicts with a DynamoDB reserved word, you can define an expression attribute name to use in the place of the reserved word. For more information, see Expression attribute names (aliases) in DynamoDB.

AWS SDK for Java 1.x examples

This section contains example code for DAX applications using SDK for Java 1.x.

Topics

- Using DAX with AWS SDK for Java 1.x
- Modifying an existing SDK for Java 1.x application to use DAX
- Querying global secondary indexes with SDK for Java 1.x

Using DAX with AWS SDK for Java 1.x

Follow this procedure to run the Java sample for Amazon DynamoDB Accelerator (DAX) on your Amazon EC2 instance.

> **Note**
>
> These instructions are for applications using AWS SDK for Java 1.x. For applications using AWS SDK for Java 2.x, see Java and DAX.

To run the Java sample for DAX

1. Install the Java Development Kit (JDK).

```
sudo yum install -y java-devel
```

2. Download the AWS SDK for Java (`.zip` file), and then extract it.

```
wget http://sdk-for-java.amazonwebservices.com/latest/aws-java-sdk.zip

unzip aws-java-sdk.zip
```

3. Download the latest version of the DAX Java client (`.jar` file).

```
wget http://dax-sdk.s3-website-us-west-2.amazonaws.com/java/DaxJavaClient-
latest.jar
```

> **Note**
>
> The client for the DAX SDK for Java is available on Apache Maven. For more information, see Using the client as an Apache Maven dependency.

4. Set your CLASSPATH variable. In this example, replace *`sdkVersion`* with the actual version number of the AWS SDK for Java (for example, `1.11.112`).

```
export SDKVERSION=sdkVersion

export CLASSPATH=$(pwd)/TryDax/java:$(pwd)/DaxJavaClient-latest.jar:$(pwd)/
aws-java-sdk-$SDKVERSION/lib/aws-java-sdk-$SDKVERSION.jar:$(pwd)/aws-java-sdk-
$SDKVERSION/third-party/lib/*
```

5. Download the sample program source code (`.zip` file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

6. Navigate to the Java code directory and compile the code as follows.

```
cd TryDax/java/
```

```
javac TryDax*.java
```

7. Run the program.

```
java TryDax
```

You should see output similar to the following.

```
Creating a DynamoDB client

Attempting to create table; please wait...
Successfully created table.  Table status: ACTIVE
Writing data to the table...

Running GetItem, Scan, and Query tests...
First iteration of each test will result in cache misses
Next iterations are cache hits

GetItem test - partition key 1 and sort keys 1-10
 Total time: 136.681 ms - Avg time: 13.668 ms
 Total time: 122.632 ms - Avg time: 12.263 ms
 Total time: 167.762 ms - Avg time: 16.776 ms
 Total time: 108.130 ms - Avg time: 10.813 ms
 Total time: 137.890 ms - Avg time: 13.789 ms
Query test - partition key 5 and sort keys between 2 and 9
 Total time: 13.560 ms - Avg time: 2.712 ms
 Total time: 11.339 ms - Avg time: 2.268 ms
 Total time: 7.809 ms - Avg time: 1.562 ms
 Total time: 10.736 ms - Avg time: 2.147 ms
 Total time: 12.122 ms - Avg time: 2.424 ms
Scan test - all items in the table
 Total time: 58.952 ms - Avg time: 11.790 ms
 Total time: 25.507 ms - Avg time: 5.101 ms
```

```
 Total time: 37.660 ms - Avg time: 7.532 ms
 Total time: 26.781 ms - Avg time: 5.356 ms
 Total time: 46.076 ms - Avg time: 9.215 ms

Attempting to delete table; please wait...
Successfully deleted table.
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

8. In the previous step, you ran the program against the DynamoDB endpoint. Now run the program again, but this time, the `GetItem`, `Query`, and `Scan` operations are processed by your DAX cluster.

   To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

     ```
     dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
     ```

   - **Using the AWS CLI** — Enter the following command.

     ```
     aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
     ```

     The cluster endpoint is shown in the output, as in the following example.

     ```
     {
         "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
         "Port": 8111,
         "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
     }
     ```

   Now run the program again, but this time, specify the cluster endpoint as a command line parameter.

   ```
   java TryDax dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
   ```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

For more information about this program, see the following sections:

- TryDax.java
- TryDaxHelper.java
- TryDaxTests.java

Using the client as an Apache Maven dependency

Follow these steps to use the client for the DAX SDK for Java in your application as a dependency.

To use the client as a Maven dependency

1. Download and install Apache Maven. For more information, see Downloading Apache Maven and Installing Apache Maven.
2. Add the client Maven dependency to your application's Project Object Model (POM) file. In this example, replace `x.x.x.x` with the actual version number of the client (for example, `1.0.200704.0`).

```
<!--Dependency:-->
<dependencies>
    <dependency>
     <groupId>com.amazonaws</groupId>
     <artifactId>amazon-dax-client</artifactId>
     <version>x.x.x.x</version>
    </dependency>
</dependencies>
```

TryDax.java

The `TryDax.java` file contains the `main` method. If you run the program with no command line parameters, it creates an Amazon DynamoDB client and uses that client for all API operations. If you specify a DynamoDB Accelerator (DAX) cluster endpoint on the command line, the program also creates a DAX client and uses it for `GetItem`, `Query`, and `Scan` operations.

You can modify the program in several ways:

- Use the DAX client instead of the DynamoDB client. For more information, see Java and DAX.
- Choose a different name for the test table.
- Modify the number of items written by changing the `helper.writeData` parameters. The second parameter is the number of partition keys, and the third parameter is the number of sort keys. By default, the program uses 1–10 for partition key values and 1–10 for sort key values, for a total of 100 items written to the table. For more information, see TryDaxHelper.java.
- Modify the number of `GetItem`, `Query`, and `Scan` tests, and modify their parameters.
- Comment out the lines containing `helper.createTable` and `helper.deleteTable` (if you don't want to create and delete the table each time you run the program).

Note

To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the client as an Apache Maven dependency.
Alternatively, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX for an example of setting your `CLASSPATH` variable.

```
public class TryDax {

    public static void main(String[] args) throws Exception {

        TryDaxHelper helper = new TryDaxHelper();
        TryDaxTests tests = new TryDaxTests();

        DynamoDB ddbClient = helper.getDynamoDBClient();
        DynamoDB daxClient = null;
        if (args.length >= 1) {
            daxClient = helper.getDaxClient(args[0]);
        }

        String tableName = "TryDaxTable";
```

```
        System.out.println("Creating table...");
        helper.createTable(tableName, ddbClient);
        System.out.println("Populating table...");
        helper.writeData(tableName, ddbClient, 10, 10);

        DynamoDB testClient = null;
        if (daxClient != null) {
            testClient = daxClient;
        } else {
            testClient = ddbClient;
        }

        System.out.println("Running GetItem, Scan, and Query tests...");
        System.out.println("First iteration of each test will result in cache misses");
        System.out.println("Next iterations are cache hits\n");

        // GetItem
        tests.getItemTest(tableName, testClient, 1, 10, 5);

        // Query
        tests.queryTest(tableName, testClient, 5, 2, 9, 5);

        // Scan
        tests.scanTest(tableName, testClient, 5);

        helper.deleteTable(tableName, ddbClient);
    }

}
```

TryDaxHelper.java

The `TryDaxHelper.java` file contains utility methods.

The `getDynamoDBClient` and `getDaxClient` methods provide Amazon DynamoDB and DynamoDB Accelerator (DAX) clients. For control plane operations (`CreateTable`, `DeleteTable`) and write operations, the program uses the DynamoDB client. If you specify a DAX cluster endpoint, the main program creates a DAX client for performing read operations (`GetItem`, `Query`, `Scan`).

The other `TryDaxHelper` methods (`createTable`, `writeData`, `deleteTable`) are for setting up and tearing down the DynamoDB table and its data.

You can modify the program in several ways:

- Use different provisioned throughput settings for the table.
- Modify the size of each item written (see the `stringSize` variable in the `writeData` method).
- Modify the number of `GetItem`, `Query`, and `Scan` tests and their parameters.
- Comment out the lines containing `helper.CreateTable` and `helper.DeleteTable` (if you don't want to create and delete the table each time you run the program).

            e.printStackTrace();
        }
    }

}
```

TryDaxTests.java

The `TryDaxTests.java` file contains methods that perform read operations against a test table in Amazon DynamoDB. These methods are not concerned with how they access the data (using either the DynamoDB client or the DAX client), so there is no need to modify the application logic.

You can modify the program in several ways:

- Modify the `queryTest` method so that it uses a different `KeyConditionExpression`.
- Add a `ScanFilter` to the `scanTest` method so that only some of the items are returned to you.

> **Note**
>
> To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the client as an Apache Maven dependency.
> Or, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX for an example of setting your `CLASSPATH` variable.

                }
            } catch (Exception e) {
                System.err.println("Unable to query table:");
                e.printStackTrace();
            }
            endTime = System.nanoTime();
            printTime(startTime, endTime, iterations);
        }
    }
```

```
    void scanTest(String tableName, DynamoDB client, int iterations) {
        long startTime, endTime;
        System.out.println("Scan test - all items in the table");
        Table table = client.getTable(tableName);

        for (int i = 0; i < iterations; i++) {
            startTime = System.nanoTime();
            ItemCollection<ScanOutcome> items = table.scan();
            try {

                Iterator<Item> iter = items.iterator();
                while (iter.hasNext()) {
                    iter.next();
                }
            } catch (Exception e) {
                System.err.println("Unable to scan table:");
                e.printStackTrace();
            }
            endTime = System.nanoTime();
            printTime(startTime, endTime, iterations);
        }
    }

    public void printTime(long startTime, long endTime, int iterations) {
        System.out.format("\tTotal time: %.3f ms - ", (endTime - startTime) /
 (1000000.0));
        System.out.format("Avg time: %.3f ms\n", (endTime - startTime) / (iterations *
 1000000.0));
    }
}
```

Modifying an existing SDK for Java 1.x application to use DAX

If you already have a Java application that uses Amazon DynamoDB, you have to modify it so that it can access your DynamoDB Accelerator (DAX) cluster. You don't have to rewrite the entire application because the DAX Java client is similar to the DynamoDB low-level client included in the AWS SDK for Java.

> **Note**
>
> These instructions are for applications using AWS SDK for Java 1.x. For applications using AWS SDK for Java 2.x, see Modifying an existing application to use DAX.

Suppose that you have a DynamoDB table named `Music`. The partition key for the table is `Artist`, and its sort key is `SongTitle`. The following program reads an item directly from the `Music` table.

```
import java.util.HashMap;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class GetMusicItem {

    public static void main(String[] args) throws Exception {

        // Create a DynamoDB client
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

        HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
        key.put("Artist", new AttributeValue().withS("No One You Know"));
        key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

        GetItemRequest request = new GetItemRequest()
            .withTableName("Music").withKey(key);

        try {
            System.out.println("Attempting to read the item...");
            GetItemResult result = client.getItem(request);
            System.out.println("GetItem succeeded: " + result);

        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }
    }
}
```

To modify the program, replace the DynamoDB client with a DAX client.

```
import java.util.HashMap;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class GetMusicItem {

    public static void main(String[] args) throws Exception {

    //Create a DAX client

    AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
    daxClientBuilder.withRegion("us-
east-1").withEndpointConfiguration("mydaxcluster.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com
    AmazonDynamoDB client = daxClientBuilder.build();

       /*
       ** ...
       ** Remaining code omitted (it is identical)
       ** ...
       */

    }
}
```

Using the DynamoDB document API

The AWS SDK for Java provides a document interface for DynamoDB. The document API acts as a wrapper around the low-level DynamoDB client. For more information, see Document interfaces.

The document interface can also be used with the low-level DAX client, as shown in the following example.

```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.GetItemOutcome;
```

```
import com.amazonaws.services.dynamodbv2.document.Table;

public class GetMusicItemWithDocumentApi {

    public static void main(String[] args) throws Exception {

        //Create a DAX client

        AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
        daxClientBuilder.withRegion("us-
east-1").withEndpointConfiguration("mydaxcluster.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com
        AmazonDynamoDB client = daxClientBuilder.build();

        // Document client wrapper
        DynamoDB docClient = new DynamoDB(client);

        Table table = docClient.getTable("Music");

        try {
            System.out.println("Attempting to read the item...");
            GetItemOutcome outcome = table.tgetItemOutcome(
                "Artist", "No One You Know",
                "SongTitle", "Scared of My Shadow");
            System.out.println(outcome.getItem());
            System.out.println("GetItem succeeded: " + outcome);
        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }

    }
}
```

DAX async client

The `AmazonDaxClient` is synchronous. For a long-running DAX API operation, such as a `Scan` of a large table, this can block program execution until the operation is complete. If your program needs to perform other work while a DAX API operation is in progress, you can use `ClusterDaxAsyncClient` instead.

The following program shows how to use `ClusterDaxAsyncClient`, along with Java `Future`, to implement a non-blocking solution.

```
import java.util.concurrent.ExecutionException;
import java.util.concurrent.Future;

import com.amazon.dax.client.dynamodbv2.ClientConfig;
import com.amazon.dax.client.dynamodbv2.ClusterDaxAsyncClient;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.handlers.AsyncHandler;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBAsync;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class DaxAsyncClientDemo {
 public static void main(String[] args) throws Exception {

  ClientConfig daxConfig = new ClientConfig().withCredentialsProvider(new
 ProfileCredentialsProvider())
    .withEndpoints("mydaxcluster.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com:8111");

  AmazonDynamoDBAsync client = new ClusterDaxAsyncClient(daxConfig);

  HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
  key.put("Artist", new AttributeValue().withS("No One You Know"));
  key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

  GetItemRequest request = new GetItemRequest()
    .withTableName("Music").withKey(key);

  // Java Futures
  Future<GetItemResult> call = client.getItemAsync(request);
  while (!call.isDone()) {
   // Do other processing while you're waiting for the response
   System.out.println("Doing something else for a few seconds...");
   Thread.sleep(3000);
  }
  // The results should be ready by now

  try {
   call.get();

  } catch (ExecutionException ee) {
   // Futures always wrap errors as an ExecutionException.
   // The *real* exception is stored as the cause of the
```

```
    // ExecutionException
    Throwable exception = ee.getCause();
    System.out.println("Error getting item: " + exception.getMessage());
   }

   // Async callbacks
   call = client.getItemAsync(request, new AsyncHandler<GetItemRequest, GetItemResult>()
  {

    @Override
    public void onSuccess(GetItemRequest request, GetItemResult getItemResult) {
     System.out.println("Result: " + getItemResult);
    }

    @Override
    public void onError(Exception e) {
     System.out.println("Unable to read item");
     System.err.println(e.getMessage());
     // Callers can also test if exception is an instance of
     // AmazonServiceException or AmazonClientException and cast
     // it to get additional information
    }

   });
   call.get();

  }
}
```

Querying global secondary indexes with SDK for Java 1.x

You can use Amazon DynamoDB Accelerator (DAX) to query global secondary indexes using DynamoDB programmatic interfaces.

The following example demonstrates how to use DAX to query the `CreateDateIndex` global secondary index that is created in Example: Global secondary indexes using the AWS SDK for Java document API.

The `DAXClient` class instantiates the client objects that are needed to interact with the DynamoDB programming interfaces.

```
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
```

```
import software.amazon.dynamodb.datamodeling.DynamoDBMapper;
import software.amazon.dynamodb.document.DynamoDB;
import com.amazonaws.util.EC2MetadataUtils;
import software.amazon.dynamodb.AmazonDynamoDB;

public class DaxClient {

 private static final String region = EC2MetadataUtils.getEC2InstanceRegion();

 DynamoDB getDaxDocClient(String daxEndpoint) {
  System.out.println("Creating a DAX client with cluster endpoint " + daxEndpoint);
  AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();

  daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
  AmazonDynamoDB client = daxClientBuilder.build();

  return new DynamoDB(client);
 }

 DynamoDBMapper getDaxMapperClient(String daxEndpoint) {
  System.out.println("Creating a DAX client with cluster endpoint " + daxEndpoint);
  AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();

  daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
  AmazonDynamoDB client = daxClientBuilder.build();

  return new DynamoDBMapper(client);
 }
}
```

You can query a global secondary index in the following ways:

- Use the `queryIndex` method on the `QueryIndexDax` class defined in the following example. The `QueryIndexDax` takes as a parameter the client object that is returned by the `getDaxDocClient` method on the `DaxClient` class.
- If you are using the object persistence interface, use the `queryIndexMapper` method on the `QueryIndexDax` class defined in the following example. The `queryIndexMapper` takes as a parameter the client object that is returned by the `getDaxMapperClient` method defined on the `DaxClient` class.

```
import java.util.Iterator;
```

```
import software.amazon.dynamodb.datamodeling.DynamoDBMapper;
import java.util.List;
import software.amazon.dynamodb.datamodeling.DynamoDBQueryExpression;
import software.amazon.dynamodb.model.AttributeValue;
import java.util.HashMap;
import software.amazon.dynamodb.document.Item;
import software.amazon.dynamodb.document.utils.ValueMap;
import software.amazon.dynamodb.document.spec.QuerySpec;
import software.amazon.dynamodb.document.QueryOutcome;
import software.amazon.dynamodb.document.ItemCollection;
import software.amazon.dynamodb.document.Index;
import software.amazon.dynamodb.document.Table;
import software.amazon.dynamodb.document.DynamoDB;

public class QueryIndexDax {

 //This is used to query Index using the low-level interface.
 public static void queryIndex(DynamoDB client, String tableName, String indexName) {
  Table table = client.getTable(tableName);

  System.out.println("\n*********************************************************
\n");
  System.out.print("Querying index " + indexName + "...");

  Index index = table.getIndex(indexName);

  ItemCollection<QueryOutcome> items = null;

  QuerySpec querySpec = new QuerySpec();

  if (indexName == "CreateDateIndex") {
   System.out.println("Issues filed on 2013-11-01");
   querySpec.withKeyConditionExpression("CreateDate = :v_date and
 begins_with(IssueId, :v_issue)")
     .withValueMap(new ValueMap().withString(":v_date",
 "2013-11-01").withString(":v_issue", "A-"));
   items = index.query(querySpec);
  } else {
   System.out.println("\nNo valid index name provided");
   return;
  }

  Iterator<Item> iterator = items.iterator();
```

```
  System.out.println("Query: printing results...");

  while (iterator.hasNext()) {
   System.out.println(iterator.next().toJSONPretty());
  }

 }

 //This is used to query Index using the high-level mapper interface.
 public static void queryIndexMapper(DynamoDBMapper mapper, String tableName, String
 indexName) {
  HashMap<String, AttributeValue> eav = new HashMap<String, AttributeValue>();
  eav.put(":v_date", new AttributeValue().withS("2013-11-01"));
  eav.put(":v_issue", new AttributeValue().withS("A-"));
  DynamoDBQueryExpression<CreateDate> queryExpression = new
 DynamoDBQueryExpression<CreateDate>()
     .withIndexName("CreateDateIndex").withConsistentRead(false)
     .withKeyConditionExpression("CreateDate = :v_date and
 begins_with(IssueId, :v_issue)")
     .withExpressionAttributeValues(eav);

  List<CreateDate> items = mapper.query(CreateDate.class, queryExpression);
  Iterator<CreateDate> iterator = items.iterator();

  System.out.println("Query: printing results...");

  while (iterator.hasNext()) {
   CreateDate iterObj = iterator.next();
   System.out.println(iterObj.getCreateDate());
   System.out.println(iterObj.getIssueId());
  }
 }
}
```

The class definition below represents the Issues table and is used in the `queryIndexMapper` method.

```
import software.amazon.dynamodb.datamodeling.DynamoDBTable;
import software.amazon.dynamodb.datamodeling.DynamoDBIndexHashKey;
import software.amazon.dynamodb.datamodeling.DynamoDBIndexRangeKey;
import software.amazon.dynamodb.datamodeling.DynamoDBHashKey;

@DynamoDBTable(tableName = "Issues")
```

```
public class CreateDate {
 private String createDate;
 @DynamoDBHashKey(attributeName = "IssueId")
 private String issueId;

 @DynamoDBIndexHashKey(globalSecondaryIndexName = "CreateDateIndex", attributeName =
 "CreateDate")
 public String getCreateDate() {
  return createDate;
 }

 public void setCreateDate(String createDate) {
  this.createDate = createDate;
 }

 @DynamoDBIndexRangeKey(globalSecondaryIndexName = "CreateDateIndex", attributeName =
 "IssueId")
 public String getIssueId() {
  return issueId;
 }

 public void setIssueId(String issueId) {
  this.issueId = issueId;
 }
}
```

AWS SDK for Go 1.x examples

This section contains example code for DAX applications using Go 1.x.

Topics

- DAX SDK for Go

DAX SDK for Go

Follow this procedure to run the Amazon DynamoDB Accelerator (DAX) SDK for Go sample application on your Amazon EC2 instance.

To run the SDK for Go sample for DAX

1. Set up the SDK for Go on your Amazon EC2 instance:

a. Install the Go programming language (`Golang`).

```
sudo yum install -y golang
```

b. Test that Golang is installed and running correctly.

```
go version
```

A message like this should appear.

```
go version go1.15.5 linux/amd64
```

The remaining instructions rely on module support, which became the default with Go version 1.13.

2. Install the sample Golang application.

```
go get github.com/aws-samples/aws-dax-go-sample
```

3. Run the following Golang programs. The first program creates a DynamoDB table named `TryDaxGoTable`. The second program writes data to the table.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command create-table
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command put-item
```

4. Run the following Golang programs.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command get-item
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command query
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command scan
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

5. In the previous step, you ran the programs against the DynamoDB endpoint. Now, run the programs again, but this time, the `GetItem`, `Query`, and `Scan` operations are processed by your DAX cluster.

   To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

     ```
     dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
     ```

   - **Using the AWS CLI** — Enter the following command.

     ```
     aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
     ```

     The cluster endpoint is shown in the output, as in the following example.

     ```
     {
         "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
         "Port": 8111,
         "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
     }
     ```

   Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

   ```
   go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go
    -service dax -command get-item -endpoint my-cluster.l6fzcv.dax-clusters.us-
   east-1.amazonaws.com:8111
   ```

   ```
   go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go
    -service dax -command query -endpoint my-cluster.l6fzcv.dax-clusters.us-
   east-1.amazonaws.com:8111
   ```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go
 -service dax -command scan -endpoint my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com:8111
```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

6. Run the following Golang program to delete `TryDaxGoTable`.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command delete-table
```

AWS SDK for Node.js 2.x examples

This section contains example code for DAX applications using AWS SDK for Node.js 2.x.

Topics

- Node.js and DAX

Node.js and DAX

Follow these steps to run the Node.js sample application on your Amazon EC2 instance.

To run the Node.js sample for DAX

1. Set up Node.js on your Amazon EC2 instance, as follows:

   a. Install node version manager (nvm).

   ```
   curl -o- https://raw.githubusercontent.com/nvm-sh/nvm/v0.35.3/install.sh | bash
   ```

   b. Use nvm to install Node.js.

   ```
   nvm install 12.16.3
   ```

   c. Test that Node.js is installed and running correctly.

   ```
   node -e "console.log('Running Node.js ' + process.version)"
   ```

This should display the following message.

```
Running Node.js v12.16.3
```

2. Install the DAX Node.js client using the node package manager (`npm`).

```
npm install amazon-dax-client
```

3. Download the sample program source code (`.zip` file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

4. Run the following Node.js programs. The first program creates an Amazon DynamoDB table named `TryDaxTable`. The second program writes data to the table.

```
node 01-create-table.js
node 02-write-data.js
```

5. Run the following Node.js programs.

```
node 03-getitem-test.js
node 04-query-test.js
node 05-scan-test.js
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

6. In the previous step, you ran the programs against the DynamoDB endpoint. Run the programs again, but this time, the `GetItem`, `Query` and `Scan` operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following.

- **Using the DynamoDB console**—Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
```

- **Using the AWS CLI**—Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint is shown in the output, as in the following example.

```
{
    "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
    "Port": 8111,
    "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
}
```

Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```
node 03-getitem-test.js dax://my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com
node 04-query-test.js dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
node 05-scan-test.js dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

7. Run the following Node.js program to delete `TryDaxTable`.

```
node 06-delete-table
```

For more information about these programs, see the following sections:

- 01-create-table.js
- 02-write-data.js
- 03-getitem-test.js
- 04-query-test.js
- 05-scan-test.js

- 06-delete-table.js

01-create-table.js

The `01-create-table.js` program creates a table (`TryDaxTable`). The remaining Node.js programs in this section depend on this table.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var dynamodb = new AWS.DynamoDB(); //low-level client

var tableName = "TryDaxTable";

var params = {
  TableName: tableName,
  KeySchema: [
    { AttributeName: "pk", KeyType: "HASH" }, //Partition key
    { AttributeName: "sk", KeyType: "RANGE" }, //Sort key
  ],
  AttributeDefinitions: [
    { AttributeName: "pk", AttributeType: "N" },
    { AttributeName: "sk", AttributeType: "N" },
  ],
  ProvisionedThroughput: {
    ReadCapacityUnits: 10,
    WriteCapacityUnits: 10,
  },
};

dynamodb.createTable(params, function (err, data) {
  if (err) {
    console.error(
      "Unable to create table. Error JSON:",
      JSON.stringify(err, null, 2)
    );
  } else {
```

```
    console.log(
      "Created table. Table description JSON:",
      JSON.stringify(data, null, 2)
    );
  }
});
```

02-write-data.js

The `02-write-data.js` program writes test data to `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();

var tableName = "TryDaxTable";

var someData = "X".repeat(1000);
var pkmax = 10;
var skmax = 10;

for (var ipk = 1; ipk <= pkmax; ipk++) {
  for (var isk = 1; isk <= skmax; isk++) {
    var params = {
      TableName: tableName,
      Item: {
        pk: ipk,
        sk: isk,
        someData: someData,
      },
    };

    //
    //put item
```

```
    ddbClient.put(params, function (err, data) {
      if (err) {
        console.error("Unable to write data: ", JSON.stringify(err, null, 2));
      } else {
        console.log("PutItem succeeded");
      }
    });
  }
}
```

03-getitem-test.js

The `03-getitem-test.js` program performs `GetItem` operations on `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";

var pk = 1;
var sk = 10;
var iterations = 5;

for (var i = 0; i < iterations; i++) {
```

```
  var startTime = new Date().getTime();

  for (var ipk = 1; ipk <= pk; ipk++) {
    for (var isk = 1; isk <= sk; isk++) {
      var params = {
        TableName: tableName,
        Key: {
          pk: ipk,
          sk: isk,
        },
      };

      client.get(params, function (err, data) {
        if (err) {
          console.error(
            "Unable to read item. Error JSON:",
            JSON.stringify(err, null, 2)
          );
        } else {
          // GetItem succeeded
        }
      });
    }
  }

  var endTime = new Date().getTime();
  console.log(
    "\tTotal time: ",
    endTime - startTime,
    "ms - Avg time: ",
    (endTime - startTime) / iterations,
    "ms"
  );
}
```

04-query-test.js

The `04-query-test.js` program performs `Query` operations on `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");
```

```
var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";

var pk = 5;
var sk1 = 2;
var sk2 = 9;
var iterations = 5;

var params = {
  TableName: tableName,
  KeyConditionExpression: "pk = :pkval and sk between :skval1 and :skval2",
  ExpressionAttributeValues: {
    ":pkval": pk,
    ":skval1": sk1,
    ":skval2": sk2,
  },
};

for (var i = 0; i < iterations; i++) {
  var startTime = new Date().getTime();

  client.query(params, function (err, data) {
    if (err) {
      console.error(
        "Unable to read item. Error JSON:",
        JSON.stringify(err, null, 2)
      );
```

```
    } else {
      // Query succeeded
    }
  });

  var endTime = new Date().getTime();
  console.log(
    "\tTotal time: ",
    endTime - startTime,
    "ms - Avg time: ",
    (endTime - startTime) / iterations,
    "ms"
  );
}
```

05-scan-test.js

The `05-scan-test.js` program performs `Scan` operations on `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";
```

```
var iterations = 5;

var params = {
  TableName: tableName,
};
var startTime = new Date().getTime();
for (var i = 0; i < iterations; i++) {
  client.scan(params, function (err, data) {
    if (err) {
      console.error(
        "Unable to read item. Error JSON:",
        JSON.stringify(err, null, 2)
      );
    } else {
      // Scan succeeded
    }
  });
}

var endTime = new Date().getTime();
console.log(
  "\tTotal time: ",
  endTime - startTime,
  "ms - Avg time: ",
  (endTime - startTime) / iterations,
  "ms"
);
```

06-delete-table.js

The `06-delete-table.js` program deletes `TryDaxTable`. Run this program after you have finished testing.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});
```

```
var dynamodb = new AWS.DynamoDB(); //low-level client

var tableName = "TryDaxTable";

var params = {
  TableName: tableName,
};

dynamodb.deleteTable(params, function (err, data) {
  if (err) {
    console.error(
      "Unable to delete table. Error JSON:",
      JSON.stringify(err, null, 2)
    );
  } else {
    console.log(
      "Deleted table. Table description JSON:",
      JSON.stringify(data, null, 2)
    );
  }
});
```

Document history for DynamoDB

The following table describes the important changes in each release of the *DynamoDB Developer Guide* from July 3, 2018 onward. For notification about updates to this documentation, you can subscribe to the RSS feed (at the top left corner of this page).

Change	Description	Date
Disassociate a global table replica	Added instructions for disassociating an MREC global table replica while retaining its regional table and data. The procedure applies to same-account and multi-acc ount global tables. For more information, see Disassoci ating a global table replica.	October 20, 2026
DynamoDB export to Amazon S3 now supports filtered export	You can now export a subset of your DynamoDB table data to Amazon S3 instead of the entire table. To do this, provide key condition, filter, and projection expressions on your export request. Filtered export works with both full exports and incremental exports. For more informati on, see DynamoDB data export to Amazon S3: how it works.	October 1, 2026
Expanded agentic AI documentation with vector search guidance and AI framework connectors	Refreshed the agentic AI chapter with vector search guidance for RAG and agent memory, and added deep-dive topics for the Strands	August 31, 2026

	Agents, LangChain, and LangGraph connectors, covering session persistence, chat history, long-term agent memory, and semantic search. For more information, see Using agentic AI with DynamoDB.	
DAX now supports AWS PrivateLink in commercial and China Regions	Added guidance for using AWS PrivateLink with DynamoDB Accelerator (DAX) to help users establish private, secure connectivity to DAX control plane endpoints within the same AWS Region. For more information, see Generate infrastructure code for Amazon DynamoDB using Console-to-Code.	October 30, 2025
DynamoDB now supports Internet Protocol version 6 (IPv6)	DynamoDB now supports Internet Protocol version 6 (IPv6) addresses in your Amazon VPC when you connect to DynamoDB tables, streams, and DAX, including with AWS PrivateLink Gateway and Interface endpoints. You can use IPv6 to simplify your network stack and meet compliance requirements with a network that supports both IPv4 and IPv6.	October 3, 2025

Added documentation for the new Console-to-Code feature for DynamoDB	Console-to-Code transforms manual DynamoDB table creation steps in the AWS Management Console into automated, reproducible infrastructure code across multiple formats like AWS CDK and CloudFormation. For more information, see Generate infrastructure code for Amazon DynamoDB using Console-to-Code.	September 23, 2025
Released DynamoDB Local version 3.1.0	This update improves performance for PartiQL queries, including Joda-time dependency.	September 14, 2025

DynamoDB has enhanced its throttling diagnostics capabilities with a new CloudWatch Contributor Insights mode, added throttling exception details, and targeted CloudWatch metrics	DynamoDB provides enhanced throttling diagnostics with a new `Throttled keys` only mode in CloudWatch Contributor Insights that specifically tracks the most throttled partition keys, more detailed throttling exceptions that include structured `ThrottlingReason` fields, providing specific reason codes and resource ARNs to help identify exactly what resource is throttled and why, and 16 new targeted CloudWatch metrics that correspond to different throttling scenario, for precise monitoring of specific throttling events. For more information, see Troubleshooting throttling in DynamoDB.	August 14, 2025

Increased limit for switching between capacity modes	Increased the limit for switching a table from provisioned to on-demand capacity mode from once every 24 hours to four times every 24 hours. This change provides more flexibility for workloads that require loading large volumes of data multiple times per day or need to accommodate unexpected traffic increases . For more information, see Considerations when switching capacity modes in DynamoDB.	August 12, 2025
Released DynamoDB Local version 3.0, which migrates from AWS SDK for Java V1 to V2	This update removes the V1 dependency, improves performance, and aligns with the AWS SDK V2 package structure.	July 17, 2025
Added support for optimized shard discovery in DynamoDB Streams	The new shard discovery mechanism reduces initial discovery time, improves steady-state processin g performance, provides visibility into processin g status, and maintains consistent p100 latency across large-scale operation s. For more information, see AWS PrivateLink for Amazon DynamoDB Streams.	July 17, 2025

Added Multi-Region Strong Consistency (MRSC) support for DynamoDB global tables	DynamoDB now supports Multi-Region Strong Consistency (MRSC) for global tables with optional witness Region. MRSC allows strongly consistent reads across Regions with a Recovery Point Objective (RPO) of zero during regional failures. MRSC global tables must be deployed in exactly three Regions, with either three replicas or two replicas and one witness. For more information and available Regions, see Multi-Region strong consistency (MRSC).	June 30, 2025
Amazon DynamoDB Streams Kinesis Client Library (KCL) 2.x adapter	DynamoDB now supports an upgraded DynamoDB Streams adapter compatible with KCL 2.x and AWS SDK v2. For more information, see Migrating from KCL1.x to KCL 3.x.	June 11, 2025
Added support for running DynamoDB local in AWS CloudShell	You can now run DynamoDB local directly in your browser through the AWS Managemen t Console without downloadi ng or installing software. For more information, see Deploying DynamoDB locally on your computer.	May 19, 2025

Added support for r7i instance types in DAX	Expanded instance type options for DAX to provide more flexibility in performance and capacity. For more details about the new r7i instance types and their capabilities, see DAX encryption at rest.	April 29, 2025
New scoped-down full access policy `AmazonDynamoDBFullAccess_v2` replaces `AmazonDynamoDBFullAccess` .	Effective **April 25, 2025**, DynamoDB has deprecated the `AmazonDynamoDBFullAccess` policy and replaced it with a scoped-down policy named `AmazonDynamoDBFullAccess_v2` . For more information, see AWS managed policy: AmazonDynamoDBFullAccess_v2.	April 28, 2025

DynamoDB introduces AWS PrivateLink support for DynamoDB Streams	AWS added AWS PrivateLink support for DynamoDB Streams, enabling customers to invoke DynamoDB Streams APIs from within Amazon Virtual Private Cloud (VPC) using private network connectivity. This feature allows simplified private network access without traversing the public internet, supporting compliance and security requirements for DynamoDB workloads. For more information, see AWS PrivateLink for Amazon DynamoDB Streams.	March 26, 2025
DAX SDK For JS 3.x and Go 2.x is now available	DynamoDB Accelerator (DAX) SDK for JS 3.x is now available and is compatible with the AWS SDK for Java 3.x.	March 17, 2025
NoSQL Workbench 3.13.5 on-demand capacity mode for default table settings release	When you create a table with default settings, DynamoDB creates a table that uses on-demand capacity mode instead of provisioned capacity mode.	February 24, 2025
New best practice for configuring your DAX client	Published a new DAX prescriptive guidance best practices topic for configuring your DAX client. For more information, see Configuring your DAX client.	February 17, 2025

New best practices for bulk data operations	Published new best practices topics for working with complex data models in DynamoDB. For more information, see Best practices for using bulk data operations in DynamoDB.	January 9, 2025
Amazon DynamoDB now supports configurable point-in-time recovery (PITR)	DynamoDB now supports configurable recovery periods for PITR. You can now set the PITR period for each table to between 1 and 35 days. For more information, see Point-in-time backups for DynamoDB.	January 7, 2025
Published new topic on integrating Amazon Managed Streaming for Apache Kafka with Amazon DynamoDB	Learn how Amazon Managed Streaming for Apache Kafka integrates with Amazon DynamoDB by reading data from Apache Kafka topics and storing it in DynamoDB. For more information, see Integrating DynamoDB with Amazon Managed Streaming for Apache Kafka.	December 26, 2024
DynamoDB introduces support for a zero-ETL integration with SageMaker AI Lakehouse	DynamoDB introduces a zero-ETL integration that automates the extracting and loading of data from Amazon DynamoDB into a customer's data lake. For more informati on, see DynamoDB zero-ETL integration with SageMaker AI Lakehouse.	December 3, 2024

DynamoDB global tables now supports multi-Region strong consistency	With multi-Region strong consistency, you can build highly available multi-Region applications with a recovery point objective (RPO) of zero, achieving the highest level of resilience. For more information, see Global tables with multi-Region strong consistency.	December 3, 2024
DynamoDB managed policy update	Added two new permissions to the `AmazonDynamoDBReadOnlyAccess` managed policy: `dynamodb:GetAbacStatus` and `dynamodb:UpdateAbacStatus`. These permissions allow you to view the ABAC status and enable ABAC for your AWS account in the current Region. For more information, see AWS managed policy: AmazonDynamoDBReadOnlyAccess.	November 18, 2024

DynamoDB introduces support for attribute-based access control (ABAC)	ABAC is an authorization strategy that lets you define access permissions based on tags attached to users, roles, and AWS resources. ABAC uses tag-based conditions in your AWS Identity and Access Management (IAM) policies or other policies to allow or deny specific actions on your tables or indexes when IAM principals' tags match the tags for the tables. For more information, see Using attribute-based access control with DynamoDB.	November 18, 2024
DynamoDB introduces warm throughput for on-demand and provisioned tables	DynamoDB now supports warm throughput. Warm throughput provides visibilit y into the number of read and write operations your DynamoDB table can instantaneously support as well as the ability to pre-warm your DynamoDB tables. For more information, see DynamoDB warm throughput.	November 13, 2024

Ability to consume Amazon DynamoDB Streams records with Apache Flink	You can now consume Amazon DynamoDB Streams records with Apache Flink and leverage the Amazon Managed Service for Apache Flink to quickly build and manage end-to-end stream processing applications. For more information, see DynamoDB Streams and Apache Flink.	November 12, 2024
Published new billing topics for global tables and backups	Published two new topics regarding billing for global tables and billing for backups. For more information, see Understanding Amazon DynamoDB billing for global tables and Understanding Amazon DynamoDB billing for backups.	October 16, 2024
Amazon DynamoDB zero-ETL integration with Amazon Redshift	Amazon DynamoDB zero-ETL integration with Amazon Redshift provides a no-code, fully managed ETL pipeline with replication from DynamoDB to Amazon Redshift. For more informati on, see Amazon DynamoDB zero-ETL integration with Amazon Redshift.	October 15, 2024

Documentation-only update to add a topic about using generative AI with DynamoDB	Published a new topic that provides information about using generative AI with DynamoDB, including examples of gen AI use cases for DynamoDB. For more information, see Using generative AI with DynamoDB.	October 11, 2024
SDK now supports AWS account-based endpoints	Added documentation for account-based endpoints and the `ACCOUNT_ID_ENDPOINT_MODE` setting for SDK clients. For more information, see SDK support of AWS account-based endpoints.	September 3, 2024
Redesigned the getting started experience	Redesigned the getting started experience to consolidate information and get you started with quicker onboarding. For more information, see Getting started with DynamoDB.	August 1, 2024
DAX expansion to new Regions for Spain and Sweden	DAX is now available in Spain and Sweden Regions. For more information, see DAX cluster components.	July 30, 2024
Restructured and consolidated the DynamoDB backup and restore documentation	The DynamoDB Developer Guide has a new structure for backing up and restoring. For more information, see Backup and restore for DynamoDB.	July 2, 2024

What is Amazon DynamoDB? topic rewrite	Published a revised and updated version of the What is Amazon DynamoDB? topic. For more information, see What is Amazon DynamoDB?.	June 21, 2024
Integrate DynamoDB Streams with EventBridge	Published a new topic on integrating DynamoDB Streams with EventBridge. For more information, see Integrating with EventBridge.	June 21, 2024
DAX prescriptive guidance	Published a new best practices topic that provides you comprehensive insights for using DynamoDB Accelerator effectively. This topic covers performan ce optimization, cost management, and operation al best practices. For more information, see DAX prescriptive guidance.	June 3, 2024
Migrating a DynamoDB table from one account to another	Added a new topic on migrating DynamoDB tables from one account to another. For more information, see Migrating a DynamoDB table from one account to another.	May 29, 2024
Restructured and consolida ted the DynamoDB monitorin g and logging documentation	A new structure for monitorin g and logging in DynamoDB includes three concise chapters for metrics, logging operations, and contributor insights.	May 3, 2024

Restructured and consolidated the DynamoDB capacity mode documentation	DynamoDB guide now includes a new chapter that contains all information about the DynamoDB capacity modes – *on-demand* and *provisioned*. With this update, the *Considerations when changing read/write Capacity Mode* topic has been moved inside the Best practices chapter. This topic is now renamed as *Considerations when switching capacity modes* and includes elaborate information about the best practices when switching between the capacity modes. In addition, the guide now features a new chapter that includes all information about DynamoDB reads and writes, and capacity units consumptions for read and write operations. For more information, see DynamoDB throughput capacity, Considerations when switching capacity modes, and DynamoDB reads and writes.	May 1, 2024

Maximum number of on-demand requests	You can now specify the maximum number of on-demand requests that an individual table, index, or both, can perform. Specifying the maximum on-demand throughput will help keep your table-level usage and costs bounded and protect against inadvertent surge in consumed resources. For more information, see Maximum throughput for on-demand tables.	May 1, 2024
NoSQL Workbench operation builder improvements	NoSQL Workbench now includes native support for dark mode. Improved table and item operations in the operations builder. Item results and operation builder request information is available in JSON format. For more information, see NoSQL Workbench operation builder.	April 24, 2024

Resource-based policies for Amazon DynamoDB resources	DynamoDB now supports resource-based policies for tables, indexes, and streams. Resource-based policies let you define access permissions by specifying who has access to each resource, and the actions they are allowed to perform on each resource. For more information, see Using resource-based policies for DynamoDB.	March 20, 2024
DynamoDB managed policy update	Added a new permission `dynamodb:GetResourcePolicy` to the `AmazonDynamoDBReadOnlyAccess` managed policy. This permission provides access to read resource-based policies attached to DynamoDB resources. For more information, see AWS managed policy: AmazonDynamoDBReadOnlyAccess.	March 20, 2024

AWS PrivateLink for Amazon DynamoDB	Amazon DynamoDB now supports AWS PrivateLink. With AWS PrivateLink, you can simplify private network connectivity between virtual private clouds (VPCs), DynamoDB, and your on-premises data centers using interface VPC endpoints and private IP addresses. For more information, see AWS PrivateLink for DynamoDB.	March 19, 2024
Programming with JavaScript guide	Amazon DynamoDB presents a programming guide for AWS SDK for JavaScript. Learn about the AWS SDK for JavaScript, abstraction layers, configuring connection, handling errors, defining retry policies, managing keep-alive, and more. For more information, see Programming with JavaScript.	March 6, 2024

Programming with AWS SDK for Java 2.x guide	Created a new programming guide that goes in depth about high-level, low-level, and document interfaces, HTTP clients and their configuration, error handling, and addresses the most common configuration settings that you should consider when using the SDK for Java 2.x. For more information, see Programming Amazon DynamoDB with AWS SDK for Java 2.x.	March 5, 2024
Clone tables with NoSQL Workbench	Allow developers to use NoSQL Workbench to copy or clone tables between development environments and regions (DynamoDB Local and DynamoDB web). For more information, see Cloning tables with NoSQL Workbench.	February 26, 2024
Programming with Python guide	Created a new guide that goes in depth about both high level and low level libraries and addresses the most common configuration settings that one should consider when using the Python SDK. For more information, see Programming with Python.	January 5, 2024

Time to live (TTL) topic rewrite	Completely rewrote the TTL section of the guide. The new guide helps you get started with TTL by providing ready-to-use code snippets along the way. The current code snippets provided are in Python and Javascript. For more information, see TTL.	December 20, 2023
Best Practices for Understanding your AWS Billing and Usage Reports	Added a new section that clarifies various usage types and the charges for those usage types in DynamoDB. For more information, see Billing and usage reports.	December 15, 2023
Amazon DynamoDB zero-ETL integration with Amazon OpenSearch Service	Amazon DynamoDB now supports zero-ETL integration with Amazon OpenSearch Service, which lets you perform a search on your DynamoDB data by automatically replicating and transforming it without custom code or infrastructure. For more information, see DynamoDB zero-ETL integration with Amazon OpenSearch Service.	November 28, 2023
Migrating to DynamoDB from a relational database	Created a migration guide to help users understsand how to migrate to DynamoDB from a relational database.	November 27, 2023

Generate sample data with NoSQL Workbench	NoSQL Workbench for Amazon DynamoDB now supports creating data models directly from sample data model templates to help you design data schemas for your workloads. You can use this feature to get familiar with NoSQL data modeling best practices when building your applications on DynamoDB.	September 28, 2023
Incremental Export to S3	You can now export data that was inserted, updated or deleted, in small increments. With incremental export, you can export changed data ranging from a few megabytes to terabytes with a few clicks in the AWS Management Console, an API call, or the AWS Command Line Interface.	September 26, 2023
Data modeling for DynamoDB	You can now learn more about data modeling with DynamoDB examples that focus on specific use cases, their access patterns, and step-by-step guidance in realizing those access patterns.	July 14, 2023

Troubleshooting section	You can now find troubleshooting content for latency and throttling issues that might occur in your DynamoDB tables.	March 13, 2023
Deletion protection for Amazon DynamoDB	Deletion protection is now available for Amazon DynamoDB tables in all AWS Regions. DynamoDB now makes it possible for you to protect your tables from accidental deletion when performing regular table management operations.	March 8, 2023
CloudFormation support for KDSD in global tables	Amazon Kinesis Data Streams for DynamoDB now supports CloudFormation for DynamoDB global tables, which means you can enable streaming to an Amazon Kinesis Data Streams on your DynamoDB global tables with CloudFormation templates.	February 15, 2023
DynamoDB local supports 100 actions per transaction	You can now perform up to 100 actions in a single transaction on DynamoDB local.	February 9, 2023

Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload	You can now use the DynamoDB Well-Architected Lens, a collection of design principles and guidance that you can use for designing well-architected DynamoDB workloads.	February 3, 2023
PartiQL GovGloud availability	PartiQL—a SQL-compatible query language for Amazon DynamoDB is now supported in AWS GovCloud (US-East) and AWS GovCloud (US-West) .	December 21, 2022
Single installation suite for NoSQL Workbench and DynamoDB local	NoSQL Workbench for DynamoDB now includes a guided DynamoDB local installation process to streamline setting up your DynamoDB local development environment.	December 6, 2022
Bulk import from S3	Amazon DynamoDB now makes it easier for you to migrate and load data into new DynamoDB tables by supporting bulk data imports from Amazon S3.	August 18, 2022

Enhanced integration with Service Quotas	Service Quotas now enables you to proactively manage your account and table quotas. You can view current values, set alarms for when your utilization of a quota exceeds a configurable threshold, and more.	June 15, 2022
NoSQL Workbench adds table and GSI support	You can now use NoSQL Workbench for table and global secondary index (GSI) control plane operations such as CreateTable, UpdateTable, and DeleteTable.	June 2, 2022
Standard-infrequent access table class now available in China	Amazon DynamoDB Standard-Infrequent Access table class is available in China Regions. Reduce your DynamoDB costs by up to 60 percent, by using this new table class for tables that store infrequently accessed data.	April 18, 2022
Increase in default service quotas and table management operations	DynamoDB increased the default quota for the number of tables per account and Region from 256 to 2,500 tables, and increased the number of concurrent table management operations from 50 to 500.	March 9, 2022

Optional limiting of items with PartiQL for DynamoDB	DynamoDB can limit the number of items processed in PartiQL for DynamoDB operations as an optional parameter on each request.	March 8, 2022
AWS Backup integration available in China (Beijing and Ningxia) Regions	AWS Backup now integrates with DynamoDB in the China (Beijing and Ningxia) Regions. You can meet complianc e and business continuity requirements more easily through enhanced backup features in AWS Backup, such as cross-account and cross-Region backups.	January 26, 2022
Throughput capacity information through PartiQL API calls	DynamoDB can return the throughput capacity consumed by PartiQL API calls to help you optimize your queries and throughput costs.	January 18, 2022
AWS Backup integration	DynamoDB now helps you meet compliance and business continuity requireme nts more easily through enhanced backup features in AWS Backup, such as cross-account and cross-Region backups.	November 24, 2021

NoSQL Workbench import/export datasets in CSV	NoSQL Workbench for Amazon DynamoDB now enables you to import and automatically populate sample data to help build and visualize your data models.	October 11, 2021
Filter and retrieve Amazon DynamoDB Streams data-plane activity with AWS CloudTrail	Amazon DynamoDB now provides you more granular control of audit logging by enabling you to filter Streams data-plane API activity in AWS CloudTrail.	September 22, 2021
Updated console	The DynamoDB console is now your default console to help you manage data more easily, simplify your common tasks, and give you faster access to resources and features.	August 25, 2021
DAX SDK For Java 2.x is now available	DynamoDB Accelerator (DAX) SDK for Java 2.x is now available and is compatible with the AWS SDK for Java 2.x. You can benefit from the latest features, including non-blocking I/O.	July 29, 2021
NoSQL Workbench feature updates including control plane operations	NoSQL Workbench for Amazon DynamoDB now helps you run frequent operations more easily to modify and access table data.	July 28, 2021

DynamoDB global tables are now available in the Asia Pacific Region	DynamoDB global tables are now available in the Asia Pacific (Osaka) Region. Replicate your DynamoDB tables automatically across your choice of 22 AWS Regions.	July 28, 2021
DAX is now available in China	DynamoDB Accelerator (DAX) is now available in the China (Beijing) Region, operated by Sinnet.	July 28, 2021
DAX encryption in transit	DynamoDB Accelerator (DAX) now supports encryption in transit of data between your applications and DAX clusters, and between the nodes within a DAX cluster.	July 24, 2021
CloudFormation and CloudTrail integration	Integration with AWS CloudFormation and security enhancements with CloudFormation data-plane logging.	June 18, 2021
CloudFormation now supported for global tables	Amazon DynamoDB global tables now support AWS CloudFormation, which means you can create global tables and manage their settings with CloudFormation templates.	May 14, 2021

Amazon DynamoDB local support for Java 2.x	You now can use the AWS SDK for Java 2.x with DynamoDB local, the downloadable version of Amazon DynamoDB. With DynamoDB local, you can develop and test applicati ons by using a version of DynamoDB running in your local development environme nt without incurring any additional costs.	May 3, 2021
NoSQL Workbench now supports AWS CloudForm ation	NoSQL Workbench for Amazon DynamoDB now supports AWS CloudForm ation, so you can manage and modify DynamoDB data models with CloudFormation templates. In addition, you now can configure table capacity settings in NoSQL Workbench.	April 22, 2021
DynamoDB and AWS Amplify now feature integration	AWS Amplify now orchestra tes multiple DynamoDB global secondary index updates in a single deployment.	April 20, 2021
AWS CloudTrail to log Amazon DynamoDB Streams data-plane APIs	You now can use AWS CloudTrail to log Amazon DynamoDB Streams data-plan e API activity, and monitor and investigate item-level changes in your DynamoDB tables.	April 20, 2021

Amazon Kinesis Data Streams for Amazon DynamoDB now supports AWS CloudFormation	Amazon Kinesis Data Streams for Amazon DynamoDBnow supports AWS CloudFormation, which means you can enable streaming to an Amazon Kinesis data stream on your DynamoDB tables with CloudFormation templates. By streaming your DynamoDB data changes to a Kinesis data stream, you can build advanced streaming applications with AAmazon Kinesis services.	April 12, 2021
Amazon Keyspaces now offers FIPS 140-2 compliant endpoints	Amazon Keyspaces (for Apache Cassandra) now offers Federal Information Processing Standards (FIPS) 140-2 compliant endpoints to help you run highly regulated workloads more easily. FIPS 140-2 is a US and Canadian government standard that specifies the security requirements for cryptographic modules that protect sensitive information.	April 8, 2021
Amazon EC2 T3 instances for DAX	DAX now supports Amazon EC2 T3 instance types, which provide a baseline level of CPU performance with the ability to burst above the baseline when needed.	February 15, 2021

NoSQL Workbench for Amazon DynamoDB support for PartiQL	You now can use the NoSQL Workbench for DynamoDB to build PartiQL statements for DynamoDB.	December 4, 2020
PartiQL for DynamoDB	You now can use PartiQL for DynamoDB—a SQL-compatible query language—to interact with DynamoDB tables and run ad hoc queries by using the AWS Management Console, AWS Command Line Interface, and DynamoDB APIs for PartiQL.	November 23, 2020
Amazon Kinesis Data Streams for Amazon DynamoDB	You now can use Amazon Kinesis Data Streams for Amazon DynamoDB with your DynamoDB tables to capture item-level changes and replicate them to a Kinesis data stream.	November 23, 2020
DynamoDB table export	You can now export your DynamoDB tables to Amazon S3, enabling you to perform analytics and complex queries on your data with services like Athena, AWS Glue, and Lake Formation.	November 9, 2020

Support for empty values	DynamoDB now supports empty values for non-key String and Binary attributes in DynamoDB tables. Empty value support gives you greater flexibility to use attributes for a broader set of use cases without having to transform such attribute s before sending them to DynamoDB. List, Map, and Set data types also support empty String and Binary values.	May 18, 2020
NoSQL Workbench for Amazon DynamoDB support for Linux	NoSQL Workbench for Amazon DynamoDB is now supported on Linux- Ubuntu , Fedora and Debian.	May 4, 2020
CloudWatch Contributor Insights for DynamoDB – GA	CloudWatch Contributor Insights for DynamoDB is generally available. CloudWatch Contributor Insights for DynamoDB is a diagnostic tool that provides an at-a-glance view of your DynamoDB table's traffic trends and helps you identify your table's most frequently accessed keys (also known as hot keys).	April 2, 2020

Upgrading global tables	You now can update your global tables from version 2017.11.29 to the latest version of global tables (2019.11.21), with a few clicks in the DynamoDB Console. By upgrading the version of your global tables, you can increase the availability of your DynamoDB tables easily by extending your existing tables into additiona l AWS Regions, with no table rebuilds required.	March 16, 2020
NoSQL Workbench for Amazon DynamoDB – GA	NoSQL Workbench for Amazon DynamoDB is generally available. Use the NoSQL Workbench to design, create, query, and manage DynamoDB tables.	March 2, 2020
DAX cache cluster metrics	DAX support for new CloudWatch metrics, that allow you to better understand your DAX cluster's performance.	February 6, 2020
CloudWatch Contributor Insights for DynamoDB – Preview	CloudWatch Contributor Insights for DynamoDB is a diagnostic tool that provides an at-a-glance view of your DynamoDB table's traffic trends and helps you identify your table's most frequently accessed keys (also known as hot keys).	November 26, 2019

Adaptive capacity support for imbalanced workload	Amazon DynamoDB adaptive capacity now handles imbalanced workloads better by isolating frequently accessed items automatic ally. If your application drives disproportionately high traffic to one or more items, DynamoDB will rebalance your partitions such that frequently accessed items do not reside on the same partition.	November 26, 2019
Support for customer managed keys	DynamoDB now supports customer managed keys, which means you can have full control over how you encrypt and manage the security of your DynamoDB data.	November 25, 2019
NoSQL Workbench support for DynamoDB local (Downloadable Version)	The NoSQL Workbench now supports connecting to DynamoDB local (Download able Version) to design, create, query, and manage DynamoDB tables.	November 8, 2019

NoSQL Workbench - Preview	This is the initial release of NoSQL Workbench for DynamoDB. Use NoSQL Workbench to design, create, query, and manage DynamoDB tables. For more information, see NoSQL Workbench for Amazon DynamoDB (Preview).	September 16, 2019
DAX adds support for transactional operations using Python and .NET	DAX supports the `TransactWriteItems` and `TransactGetItems` APIs for applications written in Go, Java, .NET, Node.js, and Python. For more information, see In-Memory Acceleration with DAX.	February 14, 2019
Amazon DynamoDB local (Downloadable Version) Updates	DynamoDB local (Downloadable Version) now supports transactional APIs, on-demand read/write capacity, capacity reporting for read and write operations, and 20 global secondary indexes. For more information, see Differences Between Downloadable DynamoDB and the DynamoDB Web Service.	February 4, 2019

Amazon DynamoDB On-Demand	DynamoDB on-demand is a flexible billing option capable of serving thousands of requests per second without capacity planning. DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you pay only for what you use. For more information, see DynamoDB throughput capacity.	November 28, 2018
Amazon DynamoDB Transactions	DynamoDB transactions make coordinated, all-or-nothing changes to multiple items both within and across tables, providing atomicity, consistency, isolation, and durability (ACID) in DynamoDB. For more information, see Amazon DynamoDB Transactions.	November 27, 2018

Amazon DynamoDB encrypts all customer data at rest	DynamoDB encryption at rest provides an additional layer of data protection by securing your data in the encrypted table, including its primary key, local and global secondary indexes, streams, global tables, backups, and DAX clusters whenever the data is stored in durable media. For more informati on, see Amazon DynamoDB Encryption at Rest.	November 15, 2018
Use Amazon DynamoDB Local More Easily with the New Docker Image	Now, it's easier to use DynamoDB local, the downloadable version of DynamoDB, to help you develop and test your DynamoDB applications by using the new DynamoDB local Docker image. For more information, see DynamoDB (Downloadable Version) and Docker.	August 22, 2018

DynamoDB Accelerator (DAX) Adds Support for Encryption at Rest	DynamoDB Accelerator (DAX) now supports encryption at rest for new DAX clusters to help you accelerate reads from Amazon DynamoDB tables in security-sensitive applications that are subject to strict compliance and regulatory requirements. For more information, see DAX Encryption at Rest.	August 9, 2018
DynamoDB point-in-time recovery (PITR) adds support for restoring deleted tables	If you delete a table with point-in-time recovery enabled, a system backup is automatically created and is retained for 35 days (at no additional cost). For more information, see Before You Begin Using Point In Time Recovery.	August 7, 2018
Updates now available over RSS	You can now subscribe to the RSS feed (at the top left corner of this page) to receive notifications about updates to the Amazon DynamoDB Developer Guide.	July 3, 2018

Earlier updates

The following table describes important changes of the *DynamoDB Developer Guide* before July 3, 2018.

Change	Description	Date Changed
Go support for DAX	Now, you can enable microsecond read performance for Amazon DynamoDB tables in your applications written in the Go programming language by using the new DynamoDB Accelerator (DAX) SDK for Go. For more information, see DAX SDK for Go.	June 26, 2018
DynamoDB announces SLA	DynamoDB has released a public availability SLA. For more information, see Amazon DynamoDB Service Level Agreement.	June 19, 2018
DynamoDB continuous backups and Point-In-Time Recovery (PITR)	Point-in-time recovery helps protect your Amazon DynamoDB tables from accidental write or delete operations. With point in time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For example, suppose that a test script writes accidentally to a production DynamoDB table. With point-in-time recovery, you can restore that table to any point in time during the last 35 days. DynamoDB maintains incremental backups of your	April 25, 2018

Change	Description	Date Changed
	table. For more information, see Point-in-time backups for DynamoDB.	
Encryption at rest for DynamoDB	DynamoDB encryption at rest, available for new DynamoDB tables, helps you secure your application data in Amazon DynamoDB tables by using AWS-managed encryption keys stored in AWS Key Management Service. For more information, see DynamoDB encryption at rest.	February 8, 2018
DynamoDB Backup and restore	On-Demand Backup allows you to create full backups of your DynamoDB tables data for data archival, helping you meet your corporate and governmental regulatory requirements. You can backup tables from a few megabytes to hundreds of terabytes of data, with no impact on performance and availability to your production applications. For more information, see Backup and restore for DynamoDB.	November 29, 2017

Change	Description	Date Changed
DynamoDB Global tables	Global Tables builds upon DynamoDB's global footprint to provide you with a fully managed, multi-region, and multi-active database that provides fast, local, read and write performance for massively scaled, global applications. Global Tables replicates your Amazon DynamoDB tables automatic ally across your choice of AWS regions. For more informati on, see Global tables - multi-active, multi-Region replicati on.	November 29, 2017
Node.js support for DAX	Node.js developers can leverage DynamoDB Accelerat or (DAX), using the DAX client for Node.js. For more information, see In-memory acceleration with DynamoDB Accelerator (DAX).	October 5, 2017

Change	Description	Date Changed
VPC Endpoints for DynamoDB	DynamoDB endpoints allow Amazon EC2 instances in your Amazon VPC to access DynamoDB, without exposure to the public Internet. Network traffic between your VPC and DynamoDB does not leave the Amazon network. For more information, see Using Amazon VPC endpoints to access DynamoDB.	August 16, 2017
Auto Scaling for DynamoDB	DynamoDB auto scaling eliminates the need for manually defining or adjust provisioned throughput settings. Instead, DynamoDB auto scaling dynamical ly adjusts read and write capacity in response to actual traffic patterns. This allows a table or a global secondary index to increase its provision ed read and write capacity to handle sudden increases in traffic, without throttling. When the workload decreases , DynamoDB auto scaling decreases the provisioned capacity. For more informati on, see Managing throughpu t capacity automatically with DynamoDB auto scaling.	June 14, 2017

Change	Description	Date Changed
DynamoDB Accelerator (DAX)	DynamoDB Accelerator (DAX) is a fully managed, highly available, in-memory cache for DynamoDB that delivers up to a 10x performance improvement – from milliseconds to microseconds – even at millions of requests per second. For more information, see In-memory acceleration with DynamoDB Accelerator (DAX).	April 19, 2017
DynamoDB now supports automatic item expiration with Time to Live (TTL)	Amazon DynamoDB Time to Live (TTL) enables you to automatically delete expired items from your tables, at no additional cost. For more information, see Using time to live (TTL) in DynamoDB.	Feb 27, 2017
DynamoDB now supports Cost Allocation Tags	You can now add tags to your Amazon DynamoDB tables for improved usage categorization and more granular cost reporting. For more information, see Adding tags and labels to resources in DynamoDB.	Jan 19, 2017

Change	Description	Date Changed
New DynamoDB `DescribeLimits` API	The `DescribeLimits` API returns the current provisioned capacity limits for your AWS account in a region, both for the region as a whole and for any one DynamoDB table that you create there. It lets you determine what your current account-level limits are so that you can compare them to the provisioned capacity that you are currently using, and have plenty of time to apply for an increase before you hit a limit. For more information, see Quotas in Amazon DynamoDB and the DescribeLimits in the *Amazon DynamoDB API Reference*.	March 1, 2016

Change	Description	Date Changed
DynamoDB Console Update and New Terminology for Primary Key Attributes	The DynamoDB management console has been redesigned to be more intuitive and easy to use. As part of this update, we are introducing new terminology for primary key attributes: • **Partition Key—**also known as a *hash attribute*. • **Sort Key—**also known as a *range attribute*. Only the names have changed; the functionality remains the same. When you create a table or a secondary index, you can choose either a simple primary key (partition key only), or a composite primary key (partition key and sort key). The DynamoDB documentation has been updated to reflect these changes.	November 12, 2015

Change	Description	Date Changed
Amazon DynamoDB Storage Backend for Titan	The DynamoDB Storage Backend for Titan is a storage backend for the Titan graph database implemented on top of Amazon DynamoDB. When using the DynamoDB Storage Backend for Titan, your data benefits from the protection of DynamoDB, which runs across Amazon's high-availability data centers. The plugin is available for Titan version 0.4.4 (primarily for compatibility with existing applications) and Titan version 0.5.4 (recommended for new applications). Like other storage backends for Titan, this plugin supports the Tinkerpop stack (versions 2.4 and 2.5), including the Blueprints API and the Gremlin shell.	August 20, 2015

Change	Description	Date Changed
DynamoDB Streams, Cross-Region Replication, and Scan with Strongly Consistent Reads	DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table, and stores this information in a log for up to 24 hours. Applications can access this log and view the data items as they appeared before and after they were modified, in near real time. For more information, see Change data capture for DynamoDB Streams and the DynamoDB Streams API Reference. DynamoDB cross-region replication is a client-side solution for maintaining identical copies of DynamoDB tables across different AWS regions, in near real time. You can use cross region replicati on to back up DynamoDB tables, or to provide low-laten cy access to data where users are geographically distribut ed. The DynamoDB `Scan` operation uses eventuall y consistent reads, by default. You can use strongly consistent reads instead by setting the `Consisten`	July 16, 2015

Change	Description	Date Changed
	`tRead` parameter to true. For more information, see Read consistency for scan and Scan in the Amazon DynamoDB API Reference.	
AWS CloudTrail support for Amazon DynamoDB	DynamoDB is now integrated with CloudTrail. CloudTrail captures API calls made from the DynamoDB console or from the DynamoDB API and tracks them in log files. For more information, see Logging DynamoDB operations by using AWS CloudTrail and the AWS CloudTrail User Guide.	May 28, 2015

Change	Description	Date Changed
Improved support for Query expressions	This release adds a new `KeyConditionExpression` parameter to the `Query` API. A `Query` reads items from a table or an index using primary key values. The `KeyConditionExpression` parameter is a string that identifies primary key names, and conditions to be applied to the key values; the `Query` retrieves only those items that satisfy the expression. The syntax of `KeyConditionExpression` is similar to that of other expression parameters in DynamoDB, and allows you to define substitution variables for names and values within the expression. For more information, see Querying tables in DynamoDB.	April 27, 2015

Change	Description	Date Changed
New comparison functions for conditional writes	In DynamoDB, the `ConditionExpression` parameter determines whether a `PutItem`, `UpdateItem`, or `DeleteItem` succeeds: The item is written only if the condition evaluates to true. This release adds two new functions, `attribute_type` and `size`, for use with `ConditionExpression`. These functions allow you to perform a conditional writes based on the data type or size of an attribute in a table. For more information, see DynamoDB condition expression CLI example.	April 27, 2015

Change	Description	Date Changed
Scan API for secondary indexes	In DynamoDB, a `Scan` operation reads all of the items in a table, applies user-defined filtering criteria, and returns the selected data items to the applicati on. This same capability is now available for secondary indexes too. To scan a local secondary index or a global secondary index, you specify the index name and the name of its parent table. By default, an index `Scan` returns all of the data in the index; you can use a filter expression to narrow the results that are returned to the application. For more information, see Scanning tables in DynamoDB.	February 10, 2015

Change	Description	Date Changed
Online operations for global secondary indexes	Online indexing lets you add or remove global secondary indexes on existing tables. With online indexing, you do not need to define all of a table's indexes when you create a table; instead, you can add a new index at any time. Similarly, if you decide you no longer need an index, you can remove it at any time. Online indexing operation s are non-blocking, so that the table remains available for read and write activity while indexes are being added or removed. For more information, see Managing Global Secondary Indexes in DynamoDB.	January 27, 2015

Change	Description	Date Changed
Document model support with JSON	DynamoDB allows you to store and retrieve documents with full support for document models. New data types are fully compatible with the JSON standard and allow you to nest document elements within one another. You can use document path dereference operators to read and write individual elements, without having to retrieve the entire document. This release also introduces new expressio n parameters for specifying projections, conditions and update actions when reading or writing data items. To learn more about document model support with JSON, see Data types and Using expressions in DynamoDB.	October 7, 2014
Flexible scaling	For tables and global secondary indexes, you can increase provisioned read and write throughput capacity by any amount, provided that you stay within your per-table and per-account limits. For more information, see Quotas in Amazon DynamoDB.	October 7, 2014

Change	Description	Date Changed
Larger item sizes	The maximum item size in DynamoDB has increased from 64 KB to 400 KB. For more information, see Quotas in Amazon DynamoDB.	October 7, 2014
Improved conditional expressions	DynamoDB expands the operators that are available for conditional expressio ns, giving you additional flexibility for conditional puts, updates, and deletes. The newly available operators let you check whether an attribute does or does not exist, is greater than or less than a particular value, is between two values, begins with certain characters, and much more. DynamoDB also provides an optional *OR* operator for evaluatin g multiple conditions. By default, multiple conditions in an expression are *AND*ed together, so the expression is true only if all of its condition s are true. If you specify *OR* instead, the expression is true if one or more one condition s are true. For more informati on, see Working with items and attributes in DynamoDB.	April 24, 2014

Change	Description	Date Changed
Query filter	The DynamoDB `Query` API supports a new `QueryFilter` option. By default, a `Query` finds items that match a specific partition key value and an optional sort key condition. A `Query` filter applies conditional expressions to other, non-key attributes; if a `Query` filter is present, then items that do not match the filter conditions are discarded before the `Query` results are returned to the application. For more information, see Querying tables in DynamoDB.	April 24, 2014

Change	Description	Date Changed
Data export and import using the AWS Management Console	The DynamoDB console has been enhanced to simplify exports and imports of data in DynamoDB tables. With just a few clicks, you can set up an AWS Data Pipeline to orchestrate the workflow, and an Amazon Elastic MapReduce cluster to copy data from DynamoDB tables to an Amazon S3 bucket, or vice-versa. You can perform an export or import one time only, or set up a daily export job. You can even perform cross-region exports and imports, copying DynamoDB data from a table in one AWS region to a table in another AWS region.	March 6, 2014
Reorganized higher-level API documentation	Information about the following APIs is now easier to find: • Java: DynamoDBMappper • .NET: Document model and object-persistence model These higher-level APIs are now documented here: Higher-level programming interfaces for DynamoDB.	January 20, 2014

Change	Description	Date Changed
Global secondary indexes	DynamoDB adds support for global secondary indexes. As with a local secondary index, you define a global secondary index by using an alternate key from a table and then issuing Query requests on the index. Unlike a local secondary index, the partition key for the global secondary index does not have to be the same as that of the table; it can be any scalar attribute from the table. The sort key is optional and can also be any scalar table attribute . A global secondary index also has its own provisioned throughput settings, which are separate from those of the parent table. For more information, see Improving data access with secondary indexes in DynamoDB and Using Global Secondary Indexes in DynamoDB.	December 12, 2013

Change	Description	Date Changed
Fine-grained access control	DynamoDB adds support for fine-grained access control. This feature allows customers to specify which principals (users, groups, or roles) can access individual items and attributes in a DynamoDB table or secondary index. Applications can also leverage web identity federation to offload the task of user authentication to a third-par ty identity provider, such as Facebook, Google, or Login with Amazon. In this way, applications (including mobile apps) can handle very large numbers of users, while ensuring that no one can access DynamoDB data items unless they are authorized to do so. For more informati on, see Using IAM policy conditions for fine-grained access control.	October 29, 2013

Change	Description	Date Changed
4 KB read capacity unit size	The capacity unit size for reads has increased from 1 KB to 4 KB. This enhancement can reduce the number of provisioned read capacity units required for many applications. For example, prior to this release, reading a 10 KB item would consume 10 read capacity units; now that same 10 KB read would consume only 3 units (10 KB / 4 KB, rounded up to the next 4 KB boundary). For more information, see DynamoDB throughput capacity.	May 14, 2013
Parallel scans	DynamoDB adds support for parallel Scan operations. Applications can now divide a table into logical segments and scan all of the segments simultaneously. This feature reduces the time required for a Scan to complete, and fully utilizes a table's provisioned read capacity. For more information, see Scanning tables in DynamoDB.	May 14, 2013

Change	Description	Date Changed
Local secondary indexes	DynamoDB adds support for local secondary indexes. You can define sort key indexes on non-key attributes, and then use these indexes in Query requests. With local secondary indexes, applications can efficiently retrieve data items across multiple dimensions. For more information, see Local secondary indexes.	April 18, 2013
New API version	With this release, DynamoDB introduces a new API version (2012-08-10). The previous API version (2011-12-05) is still supported for backward compatibility with existing applications. New applications should use the new API version 2012-08-10. We recommend that you migrate your existing applications to API version 2012-08-10, since new DynamoDB features (such as local secondary indexes) will not be backported to the previous API version. For more information on API version 2012-08-10, see the Amazon DynamoDB API Reference.	April 18, 2013

Change	Description	Date Changed
IAM policy variable support	The IAM access policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based informati on from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy. For more information about policy variables, go to Policy Variables in the *AWS Identity and Access Management Using IAM* guide. For examples of policy variables in DynamoDB, see Identity and Access Management for Amazon DynamoDB.	April 4, 2013
PHP code examples updated for AWS SDK for PHP version 2	Version 2 of the AWS SDK for PHP is now available . The PHP code examples in the Amazon DynamoDB Developer Guide have been updated to use this new SDK. For more information on Version 2 of the SDK, see AWS SDK for PHP.	January 23, 2013

Change	Description	Date Changed
New endpoint	DynamoDB expands to the AWS GovCloud (US-West) region. For the current list of service endpoints and protocols, see Regions and Endpoints.	December 3, 2012
New endpoint	DynamoDB expands to the South America (São Paulo) region. For the current list of supported endpoints, see Regions and Endpoints.	December 3, 2012
New endpoint	DynamoDB expands to the Asia Pacific (Sydney) region. For the current list of supported endpoints, see Regions and Endpoints.	November 13, 2012

Change	Description	Date Changed
DynamoDB implements support for CRC32 checksums , supports strongly consisten t batch gets, and removes restrictions on concurrent table updates.	• DynamoDB calculates a CRC32 checksum of the HTTP payload and returns this checksum in a new header, `x-amz-crc32` . For more information, see DynamoDB low-level API. • By default, read operation s performed by the `BatchGetItem` API are eventually consistent. A new `ConsistentRead` parameter in `BatchGetI tem` lets you choose strong read consistency instead, for any table(s) in the request. For more information, see Descripti on. • This release removes some restrictions when updating many tables simultane ously. The total number of tables that can be updated at once is still 10; however, these tables can now be any combination of `CREATING`, `UPDATING` or `DELETING` status. Additiona lly, there is no longer any minimum amount for increasing or reducing the *ReadCapacityUnits* or *WriteCapacityUnits* for a	November 2, 2012

Change	Description	Date Changed
	table. For more informati on, see Quotas in Amazon DynamoDB.	
Best practices documentation	The Amazon DynamoDB Developer Guide identifies best practices for working with tables and items, along with recommendations for query and scan operations.	September 28, 2012

Change	Description	Date Changed
Support for binary data type	In addition to the Number and String types, DynamoDB now supports Binary data type. Prior to this release, to store binary data, you converted your binary data into string format and stored it in DynamoDB. In addition to the required conversion work on the client-side, the conversio n often increased the size of the data item requiring more storage and potential ly additional provisioned throughput capacity. With the binary type attribute s you can now store any binary data, for example compressed data, encrypted data, and images. For more information see Data types. For working examples of handling binary type data using the AWS SDKs, see the following sections: • Example: Handling binary type attributes using the AWS SDK for Java document API • Example: Handling binary type attributes using the	August 21, 2012

Change	Description	Date Changed
	AWS SDK for .NET low-level API For the added binary data type support in the AWS SDKs, you will need to download the latest SDKs and you might also need to update any existing applications. For information about downloading the AWS SDKs, see .NET code examples.	
DynamoDB table items can be updated and copied using the DynamoDB console	DynamoDB users can now update and copy table items using the DynamoDB Console, in addition to being able to add and delete items. This new functionality simplifies making changes to individual items through the Console.	August 14, 2012
DynamoDB lowers minimum table throughput requirements	DynamoDB now supports lower minimum table throughput requirements, specifically 1 write capacity unit and 1 read capacity unit. For more information, see the Quotas in Amazon DynamoDB topic in the Amazon DynamoDB Developer Guide.	August 9, 2012

Change	Description	Date Changed
Signature Version 4 support	DynamoDB now supports Signature Version 4 for authenticating requests.	July 5, 2012
Table explorer support in DynamoDB Console	The DynamoDB Console now supports a table explorer that enables you to browse and query the data in your tables. You can also insert new items or delete existing items. The `SampleData` and Using the console sections have been updated for these features.	May 22, 2012
New endpoints	DynamoDB availability expands with new endpoints in the US West (N. Californi a) region, US West (Oregon) region, and the Asia Pacific (Singapore) region. For the current list of supported endpoints, go to Regions and Endpoints.	April 24, 2012

Change	Description	Date Changed
BatchWriteItem API support	DynamoDB now supports a batch write API that enables you to put and delete several items from one or more tables in a single API call. For more information about the DynamoDB batch write API, see BatchWriteItem. For information about working with items and using batch write feature using AWS SDKs, see Working with items and attributes in DynamoDB and .NET code examples.	April 19, 2012
Documented more error codes	For more information, see Error handling with DynamoDB.	April 5, 2012
New endpoint	DynamoDB expands to the Asia Pacific (Tokyo) region. For the current list of supported endpoints, see Regions and Endpoints.	February 29, 2012
`ReturnedItemCount` metric added	A new metric, `ReturnedItemCount` , provides the number of items returned in the response of a Query or Scan operation for DynamoDB is available for monitoring through CloudWatch.	February 24, 2012

Change	Description	Date Changed
Added examples for incrementing values	DynamoDB supports incrementing and decrementing existing numeric values. Examples show adding to existing values in the "Updating an Item" sections at: Working with items: Java. Working with items: .NET.	January 25, 2012
Initial product release	DynamoDB is introduced as a new service in Beta release.	January 18, 2012

Legacy features of DynamoDB

The following topics are legacy features that DynamoDB still supports. No active development is made on these features.

Topics

- Global tables version 2017.11.29 (Legacy)
- Previous low-level DynamoDB API version (2011-12-05)
- Legacy DynamoDB conditional parameters

Global tables version 2017.11.29 (Legacy)

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
To determine which version you are using, see Determining the version of a global table.
To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see DynamoDB global tables versions.

Topics

- Global tables: How it works
- Best practices and requirements for managing global tables
- Creating a global table (Version 2017.11.29)
- Monitoring global tables
- Using IAM with global tables

Global tables: How it works

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the version of a global table.
> To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see DynamoDB global tables versions.

The following sections help you understand the concepts and behavior of global tables in Amazon DynamoDB.

Global table concepts for Version 2017.11.29 (Legacy)

A *global table* is a collection of one or more replica tables, all owned by a single AWS account.

A *replica table* (or *replica*, for short) is a single DynamoDB table that functions as a part of a global table. Each replica stores the same set of data items. Any given global table can only have one replica table per AWS Region.

The following is a conceptual overview of how a global table is created.

1. Create an ordinary DynamoDB table, with DynamoDB Streams enabled, in an AWS Region.
2. Repeat step 1 for every other Region where you want to replicate your data.
3. Define a DynamoDB global table based on the tables that you have created.

The AWS Management Console automates these tasks, so you can create a global table more quickly and easily. For more information, see Creating a global table (Version 2017.11.29).

The resulting DynamoDB global table consists of multiple replica tables, one per Region, that DynamoDB treats as a single unit. Every replica has the same table name and the same primary key schema. When an application writes data to a replica table in one Region, DynamoDB automatically propagates the write to the other replica tables in the other AWS Regions.

Important

To keep your table data in sync, global tables automatically create the following attributes for every item:

- `aws:rep:deleting`
- `aws:rep:updatetime`
- `aws:rep:updateregion`

Do not modify these attributes or create attributes with the same name.

You can add replica tables to the global table so that it can be available in additional Regions. (To do this, the global table must be empty. In other words, none of the replica tables can have any data in them.)

You can also remove a replica table from a global table. If you do this, the table is completely disassociated from the global table. This newly independent table no longer interacts with the global table, and data is no longer propagated to or from the global table.

Warning

Be aware that removing a replica isn't an atomic process. To ensure consistent behavior and known state, you may want to consider diverting your application write traffic away from the replica to be removed ahead of time. After removing it, wait until all replica Region endpoints show the replica as disassociated before making any further writes to it as its own isolated regional table.

Common tasks

Common tasks for global tables work as follows.

You can delete a global table's replica table the same as a regular table. This will stop replication to that Region and delete the table copy kept in that Region. You cannot sever the replication and have copies of the table exist as independent entities.

> **Note**
>
> You won't be able to delete a source table until at least 24 hours after it's used to initiate a new Region. If you try to delete it too soon you will receive an error.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a "last writer wins" method to reconcile between concurrent updates. All the replicas will agree on the latest update and converge toward a state in which they all have identical data.

> **Note**
>
> There are several ways to avoid conflicts, including:
>
> - Using an IAM policy to only allow writes to the table in one Region.
> - Using an IAM policy to route users to only one Region and keeping the other as an idle standby, or alternately routing odd users to one Region and even users to another Region.
> - Avoiding the use of non-idempotent updates such as Bookmark = Bookmark + 1, in favor of static updates such as Bookmark=25.

Monitoring global tables

You can use CloudWatch to observe the metric `ReplicationLatency`. This metric tracks the elapsed time between when an updated item appears in the DynamoDB stream for one replica table, and when that item appears in another replica in the global table. `ReplicationLatency` is expressed in milliseconds and is emitted for every source-Region and destination-Region pair. This is the only CloudWatch metric provided by Global Tables v2.

The latencies you will observe depend on the distance between your chosen Regions, as well as other variables. Latencies in the 0.5 to 2.5 second range for Regions can be common within the same geographic area.

Time To Live (TTL)

You can use Time To Live (TTL) to specify an attribute name whose value indicates the time of expiration for the item. This value is specified as a number in seconds since the start of the Unix epoch.

With global tables legacy version, the TTL deletes are not automatically replicated across other replicas. When an item is deleted by a TTL rule, that work is performed without consuming Write Units.

Be aware that if the source and target table have very low Provisioned write capacity, this may cause throttling as the TTL deletes require write capacity.

Streams and transactions with global tables

Each global table produces an independent stream based on all its writes, regardless of the origination point for those writes. You can choose to consume this DynamoDB stream in one Region or in all Regions independently.

If you want processed local writes but not replicated writes, you can add your own region attribute to each item. Then you can use a Lambda event filter to invoke only the Lambda for writes in the local Region.

Transactional operations provide ACID (Atomicity, Consistency, Isolation, and Durability) guarantees ONLY within the Region where the write is originally made. Transactions aren't supported across Regions in global tables.

For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and perform a TransactWriteItems operation in the US East (Ohio) Region, you may observe partially completed transactions in US West (Oregon) Region as changes are replicated. Changes will only be replicated to other Regions once they have been committed in the source Region.

Note

- Global tables “write around” DynamoDB Accelerator by updating DynamoDB directly. As a result DAX will not be aware it is holding stale data. The DAX cache will only be refreshed when the cache’s TTL expires.
- Tags on global tables do not automatically propagate.

Read and write throughput

Global tables manage read and write throughput in the following ways.

- The write capacity must be the same on all table instances across Regions.
- With Version 2019.11.21 (Current, if the table is set to support auto scaling or is in on-demand mode then the write capacity is automatically kept in sync. The current amount of write capacity provisioned in each Region will rise and fall independently within those synchronized auto scaling settings. If the table is placed in on-demand mode, that mode will sync to the other replicas.
- Read capacity can differ between Regions because reads may not be equal. When adding a global replica to a table, the capacity of the source Region is propagated. After creation you can adjust the read capacity for one replica, and this new setting isn't transferred to the other side.

Consistency and conflict resolution

Any changes made to any item in any replica table are replicated to all the other replicas within the same global table. In a global table, a newly written item is usually propagated to all replica tables within seconds.

With a global table, each replica table stores the same set of data items. DynamoDB does not support partial replication of only some of the items.

An application can read and write data to any replica table. DynamoDB supports eventually consistent reads across Regions, but does not support strongly consistent reads across Regions. If your application only uses eventually consistent reads and only issues reads against one AWS Region, it will work without any modification. However, if your application requires strongly consistent reads then it must perform all the strongly consistent reads and writes in the same Region. Otherwise, if you write to one Region and read from another Region then the read response might include stale data that doesn't reflect the results of recently completed writes in the other Region.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a *last writer wins* reconciliation between concurrent updates, in which DynamoDB makes a best effort to determine the last writer. With this conflict resolution mechanism, all the replicas will agree on the latest update and converge toward a state in which they all have identical data.

Availability and durability

If a single AWS Region becomes isolated or degraded, your application can redirect to a different Region and perform reads and writes against a different replica table. You can apply custom business logic to determine when to redirect requests to other Regions.

If a Region becomes isolated or degraded, DynamoDB keeps track of any writes that have been performed but have not yet been propagated to all of the replica tables. When the Region comes back online, DynamoDB resumes propagating any pending writes from that Region to the replica tables in other Regions. It also resumes propagating writes from other replica tables to the Region that is now back online. All previously successful writes will be propagated eventually no matter how long the Region is isolated.

Best practices and requirements for managing global tables

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the version of a global table.
> To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see DynamoDB global tables versions.

Using Amazon DynamoDB global tables, you can replicate your table data across AWS Regions. It is important that the replica tables and secondary indexes in your global table have identical write capacity settings to ensure proper replication of data.

Topics

- Global tables version
- Requirements for adding a new replica table
- Best practices and requirements for managing capacity

Global tables version

There are two versions of DynamoDB global tables available: Global Tables version 2019.11.21 (Current) and Global tables version 2017.11.29 (Legacy). Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see Determining the version of a global table. To update existing global tables from Version 2017.11.29 (Legacy) to Version 2019.11.21 (Current), see Upgrading global tables.

Requirements for adding a new replica table

If you want to add a new replica table to a global table, each of the following conditions must be true:

- The table must have the same partition key as all of the other replicas.
- The table must have the same write capacity management settings specified.
- The table must have the same name as all of the other replicas.
- The table must have DynamoDB Streams enabled, with the stream containing both the new and the old images of the item.
- None of the new or existing replica tables in the global table can contain any data.

If global secondary indexes are specified, the following conditions must also be met:

- The global secondary indexes must have the same name.
- The global secondary indexes must have the same partition key and sort key (if present).

> **Important**
>
> Write capacity settings should be set consistently across all of your global tables' replica tables and matching secondary indexes. To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the `UpdateGlobalTableSettings` API operation. `UpdateGlobalTableSettings` applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the `UpdateTable`, `RegisterScalableTarget`,

or `PutScalingPolicy` operations, you should apply the change to each replica table and matching secondary index individually. For more information, see UpdateGlobalTableSettings in the Amazon DynamoDB API Reference.
We strongly recommend that you enable auto scaling to manage provisioned write capacity settings. If you prefer to manage write capacity settings manually, you should provision equal replicated write capacity units to all of your replica tables. Also provision equal replicated write capacity units to matching secondary indexes across your global table.
You must also have appropriate AWS Identity and Access Management (IAM) permissions. For more information, see Using IAM with global tables.

Best practices and requirements for managing capacity

Consider the following when managing capacity settings for replica tables in DynamoDB.

Using DynamoDB auto scaling

Using DynamoDB auto scaling is the recommended way to manage throughput capacity settings for replica tables that use the provisioned mode. DynamoDB auto scaling automatically adjusts read capacity units (RCUs) and write capacity units (WCUs) for each replica table based upon your actual application workload. For more information, see Managing throughput capacity automatically with DynamoDB auto scaling.

If you create your replica tables using the AWS Management Console, auto scaling is enabled by default for each replica table, with default auto scaling settings for managing read capacity units and write capacity units.

Changes to auto scaling settings for a replica table or secondary index made through the DynamoDB console or using the `UpdateGlobalTableSettings` call are applied to all of the replica tables and matching secondary indexes in the global table automatically. These changes overwrite any existing auto scaling settings. This ensures that provisioned write capacity settings are consistent across the replica tables and secondary indexes in your global table. If you use the `UpdateTable`, `RegisterScalableTarget`, or `PutScalingPolicy` calls, you should apply the change to each replica table and matching secondary index individually.

Note

If auto scaling doesn't satisfy your application's capacity changes (unpredictable workload), or if you don't want to configure its settings (target settings for minimum, maximum, or

utilization threshold), you can use on-demand mode to manage capacity for your global tables. For more information, see On-demand mode.
If you enable on-demand mode on a global table, your consumption of replicated write request units (rWCUs) will be consistent with how rWCUs are provisioned. For example, if you perform 10 writes to a local table that is replicated in two additional Regions, you will consume 60 write request units (10 + 10 + 10 = 30; 30 x 2 = 60). The consumed 60 write request units include the extra write consumed by global tables Version 2017.11.29 (Legacy) to update the `aws:rep:deleting`, `aws:rep:updatetime`, and `aws:rep:updateregion` attributes.

Managing capacity manually

If you decide not to use DynamoDB auto scaling, you must manually set the read capacity and write capacity settings on each replica table and secondary index.

The provisioned replicated write capacity units (rWCUs) on every replica table should be set to the total number of rWCUs needed for application writes across all Regions multiplied by two. This accommodates application writes that occur in the local Region and replicated application writes coming from other Regions. For example, suppose that you expect 5 writes per second to your replica table in Ohio and 5 writes per second to your replica table in N. Virginia. In this case, you should provision 20 rWCUs to each replica table (5 + 5 = 10; 10 x 2 = 20).

To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the `UpdateGlobalTableSettings` API operation. `UpdateGlobalTableSettings` applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the `UpdateTable`, `RegisterScalableTarget`, or `PutScalingPolicy` operations, you should apply the change to each replica table and matching secondary index individually. For more information, see Amazon DynamoDB API Reference.

Note

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions. For more information, see Using IAM with global tables.

Creating a global table (Version 2017.11.29)

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the version of a global table.
> To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see DynamoDB global tables versions.

This section describes how to create a global table using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

Topics

- Creating a global table (console)
- Creating a global table (AWS CLI)

Creating a global table (console)

Follow these steps to create a global table using the console. The following example creates a global table with replica tables in United States and Europe.

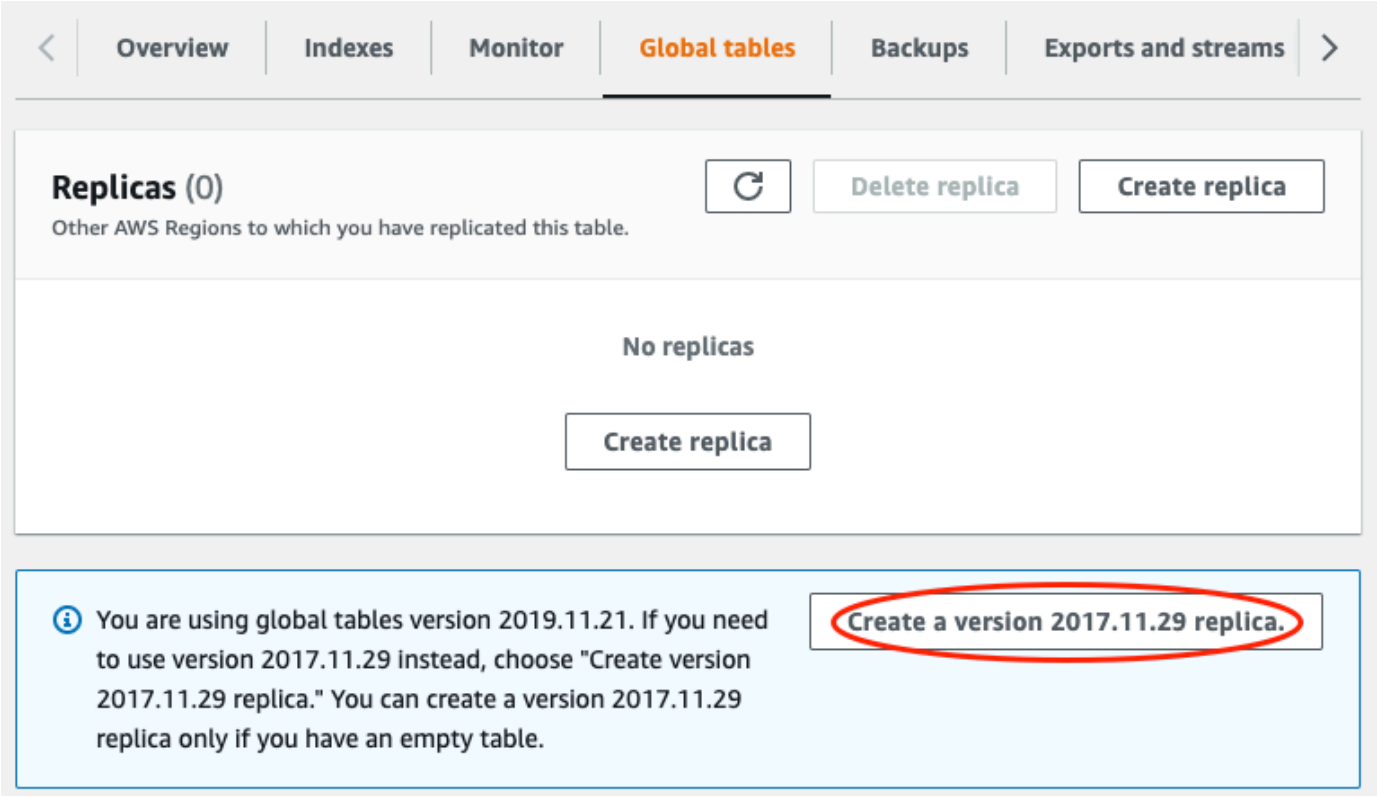
1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/home. For this example, choose the us-east-2 (US East Ohio) Region.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose **Create Table**.

   For **Table name**, enter **`Music`**.

   For **Primary key** enter **`Artist`**. Choose **Add sort key**, and enter **`SongTitle`**. (**`Artist`** and **`SongTitle`** should both be strings.)

   To create the table, choose **Create**. This table serves as the first replica table in a new global table. It is the prototype for other replica tables that you add later.

4. Choose the **Global Tables** tab, and then choose **Create a Version 2017.11.29 (Legacy) replica**.



5. From the **Available replication Regions** dropdown, choose **US West (Oregon)**.

   The console checks to make sure that a table with the same name doesn't exist in the selected Region. If a table with the same name does exist, you must delete the existing table before you can create a new replica table in that Region.

6. Choose **Create Replica**. This starts the table creation process in US West (Oregon);.

   The **Global Table** tab for the selected table (and for any other replica tables) shows that the table has been replicated in multiple Regions.

7. Now add another Region so that your global table is replicated and synchronized across the United States and Europe. To do this, repeat step 5, but this time, specify **Europe (Frankfurt)** instead of **US West (Oregon)**.

8. You should still be using the AWS Management Console in the US East (Ohio) Region. Select **Items** in the left navigation menu, select the **Music** table, then choose **Create Item**.

   a. For **Artist**, enter **`item_1`**.

   b. For **SongTitle**, enter **`Song Value 1`**.

   c. To write the item, choose **Create item**.

9. After a short time, the item is replicated across all three Regions of your global table. To verify this, in the console, on the Region selector in the upper-right corner, choose **Europe (Frankfurt)**. The `Music` table in Europe (Frankfurt) should contain the new item.
10. Repeat step 9 and choose **US West (Oregon)** to verify replication in that region.

Creating a global table (AWS CLI)

Follow these steps to create a global table `Music` using the AWS CLI. The following example creates a global table, with replica tables in the United States and in Europe.

1. Create a new table (`Music`) in US East (Ohio), with DynamoDB Streams enabled (`NEW_AND_OLD_IMAGES`).

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
    --region us-east-2
```

2. Create an identical `Music` table in US East (N. Virginia).

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
    --region us-east-1
```

3. Create a global table (`Music`) consisting of replica tables in the `us-east-2` and `us-east-1` Regions.

```
aws dynamodb create-global-table \
    --global-table-name Music \
    --replication-group RegionName=us-east-2 RegionName=us-east-1 \
    --region us-east-2
```

> **Note**
>
> The global table name (`Music`) must match the name of each of the replica tables (`Music`). For more information, see Best practices for global tables.

4. Create another table in Europe (Ireland), with the same settings as those you created in step 1 and step 2.

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
    --region eu-west-1
```

After doing this step, add the new table to the `Music` global table.

```
aws dynamodb update-global-table \
    --global-table-name Music \
    --replica-updates 'Create={RegionName=eu-west-1}' \
    --region us-east-2
```

5. To verify that replication is working, add a new item to the `Music` table in US East (Ohio).

```
aws dynamodb put-item \
    --table-name Music \
```

```
    --item '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region us-east-2
```

6. Wait for a few seconds, and then check to see whether the item has been successfully replicated to US East (N. Virginia) and Europe (Ireland).

```
aws dynamodb get-item \
    --table-name Music \
    --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region us-east-1
```

```
aws dynamodb get-item \
    --table-name Music \
    --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region eu-west-1
```

Monitoring global tables

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the version of a global table.
> To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see DynamoDB global tables versions.

You can use Amazon CloudWatch to monitor the behavior and performance of a global table. Amazon DynamoDB publishes `ReplicationLatency` and `PendingReplicationCount` metrics for each replica in the global table.

- **`ReplicationLatency`**—The elapsed time between when an updated item appears in the DynamoDB stream for one replica table, and when that item appears in another replica in the global table. `ReplicationLatency` is expressed in milliseconds and is emitted for every source- and destination-Region pair.

During normal operation, `ReplicationLatency` should be fairly constant. An elevated value for `ReplicationLatency` could indicate that updates from one replica are not propagating to other replica tables in a timely manner. Over time, this could result in other replica tables *falling behind* because they no longer receive updates consistently. In this case, you should verify that the read capacity units (RCUs) and write capacity units (WCUs) are identical for each of the replica tables. In addition, when choosing WCU settings, follow the recommendations in Global tables version.

`ReplicationLatency` can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

- **`PendingReplicationCount`**—The number of item updates that are written to one replica table, but that have not yet been written to another replica in the global table. `PendingReplicationCount` is expressed in number of items and is emitted for every source- and destination-Region pair.

  During normal operation, `PendingReplicationCount` should be very low. If `PendingReplicationCount` increases for extended periods, investigate whether your replica tables' provisioned write capacity settings are sufficient for your current workload.

  `PendingReplicationCount` can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

For more information, see DynamoDB Metrics and dimensions.

Using IAM with global tables

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see Determining the version of a global table. To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see DynamoDB global tables versions.

When you create a global table for the first time, Amazon DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role is named , and it allows DynamoDB to manage cross-Region replication for global tables on your behalf. Don't delete this service-linked role. If you do, then all of your global tables will no longer function.

For more information about service-linked roles, see Using service-linked roles in the *IAM User Guide*.

To create and maintain global tables in DynamoDB, you must have the `dynamodb:CreateGlobalTable` permission to access each of the following:

- The replica table that you want to add.
- Each existing replica that's already part of the global table.
- The global table itself.

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions.

The `application-autoscaling:DeleteScalingPolicy` and `application-autoscaling:DeregisterScalableTarget` permissions are required when updating an existing scaling policy. This is so that the global tables service can remove the old scaling policy before attaching the new policy to the table or secondary index.

If you use an IAM policy to manage access to one replica table, you should apply an identical policy to all other replicas within that global table. This practice helps you maintain a consistent permissions model across all of the replica tables.

By using identical IAM policies on all replicas in a global table, you can also avoid granting unintended read and write access to your global table data. For example, consider a user who has access to only one replica in a global table. If that user can write to this replica, DynamoDB propagates the write to all of the other replica tables. In effect, the user can (indirectly) write to

all of the other replicas in the global table. This scenario can be avoided by using consistent IAM policies on all of the replica tables.

Example: Allow the CreateGlobalTable action

Before you can add a replica to a global table, you must have the `dynamodb:CreateGlobalTable` permission for the global table and for each of its replica tables.

The following IAM policy grants permissions to allow the `CreateGlobalTable` action on all tables.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:CreateGlobalTable"],
            "Resource": "*"
        }
    ]
}
```

Example: Allow the UpdateGlobalTable, DescribeLimits, application-autoscaling:DeleteScalingPolicy, and application-autoscaling:DeregisterScalableTarget actions

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions.

The following IAM policy grants permissions to allow the `UpdateGlobalTableSettings` action on all tables.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:UpdateGlobalTable",
                "dynamodb:DescribeLimits",
                "application-autoscaling:DeleteScalingPolicy",
                "application-autoscaling:DeregisterScalableTarget"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Allow the CreateGlobalTable action for a specific global table name with replicas allowed in certain regions only

The following IAM policy grants permissions to allow the `CreateGlobalTable` action to create a global table named `Customers` with replicas in two Regions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dynamodb:CreateGlobalTable",
            "Resource": [
                "arn:aws:dynamodb::123456789012:global-table/Customers",
                "arn:aws:dynamodb:us-east-1:123456789012:table/Customers",
                "arn:aws:dynamodb:us-west-1:123456789012:table/Customers"
            ]
        }
    ]
}
```

Previous low-level DynamoDB API version (2011-12-05)

This section documents the operations available in the previous DynamoDB low-level API version (2011-12-05). This version of the low-level API is maintained for backward compatibility with existing applications.

New applications should use the current API version (2012-08-10). For more information, see DynamoDB API reference.

> **Note**
>
> We recommend that you migrate your applications to the latest API version (2012-08-10), since new DynamoDB features will not be backported to the previous API version.

BatchGetItem

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

The `BatchGetItem` operation returns the attributes for multiple items from multiple tables using their primary keys. The maximum number of items that can be retrieved for a single operation is 100. Also, the number of items retrieved is constrained by a 1 MB size limit. If the response size limit is exceeded or a partial result is returned because the table's provisioned throughput is exceeded, or because of an internal processing failure, DynamoDB returns an `UnprocessedKeys` value so you can retry the operation starting with the next item to get. DynamoDB automatically adjusts the number of items returned per page to enforce this limit. For example, even if you ask to retrieve 100 items, but each individual item is 50 KB in size, the system returns 20 items and an appropriate `UnprocessedKeys` value so you can get the next page of results. If desired, your application can include its own logic to assemble the pages of results into one set.

If no items could be processed because of insufficient provisioned throughput on each of the tables involved in the request, DynamoDB returns a `ProvisionedThroughputExceededException` error.

Note

By default, `BatchGetItem` performs eventually consistent reads on every table in the request. You can set the `ConsistentRead` parameter to `true`, on a per-table basis, if you want consistent reads instead.

`BatchGetItem` fetches items in parallel to minimize response latencies.

When designing your application, keep in mind that DynamoDB does not guarantee how attributes are ordered in the returned response. Include the primary key values in the `AttributesToGet` for the items in your request to help parse the response by item.

If the requested items do not exist, nothing is returned in the response for those items. Requests for non-existent items consume the minimum read capacity units according to the type of read. For more information, see DynamoDB item sizes and formats.

Requests

Syntax

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{"RequestItems":
    {"Table1":
        {"Keys":
            [{"HashKeyElement": {"S":"KeyValue1"}, "RangeKeyElement":
{"N":"KeyValue2"}},
            {"HashKeyElement": {"S":"KeyValue3"}, "RangeKeyElement":{"N":"KeyValue4"}},
            {"HashKeyElement": {"S":"KeyValue5"}, "RangeKeyElement":
{"N":"KeyValue6"}}],
        "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]},
    "Table2":
        {"Keys":
            [{"HashKeyElement": {"S":"KeyValue4"}},
            {"HashKeyElement": {"S":"KeyValue5"}}],
        "AttributesToGet": ["AttributeName4", "AttributeName5", "AttributeName6"]
        }
    }
}
```

Name	Description	Required
RequestItems	A container of the table name and corresponding items to get by primary key. While requesting items, each table	Yes

Name	Description	Required
	name can be invoked only once per operation. Type: String Default: None	
`Table`	The name of the table containing the items to get. The entry is simply a string specifying an existing table with no label. Type: String Default: None	Yes
`Table:Keys`	The primary key values that define the items in the specified table. For more information about primary keys, see Primary key. Type: Keys	Yes
`Table:AttributesToGet`	Array of Attribute names within the specified table. If attribute names are not specified then all attribute s will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No

Name	Description	Required
Table:ConsistentRead	If set to `true`, then a consistent read is issued, otherwise eventually consistent is used. Type: Boolean	No

Responses

Syntax

```
HTTP/1.1 200

        "AttributeName3": {"SS":["AttributeValue", "AttributeValue", "AttributeValue"]}
        },
        {"AttributeName1": {"S": "AttributeValue"},
        "AttributeName2": {"S": "AttributeValue"},
        "AttributeName3": {"NS": ["AttributeValue", "AttributeValue",
 "AttributeValue"]}
        }],
    "ConsumedCapacityUnits":1},
    "Table2":
        {"Items":
        [{"AttributeName1": {"S":"AttributeValue"},
        "AttributeName2": {"N":"AttributeValue"},
        "AttributeName3": {"SS":["AttributeValue", "AttributeValue", "AttributeValue"]}
        },
        {"AttributeName1": {"S": "AttributeValue"},
        "AttributeName2": {"S": "AttributeValue"},
        "AttributeName3": {"NS": ["AttributeValue", "AttributeValue","AttributeValue"]}
        }],
```

```
    "ConsumedCapacityUnits":1}
    },
    "UnprocessedKeys":
        {"Table3":
        {"Keys":
            [{"HashKeyElement": {"S":"KeyValue1"}, "RangeKeyElement":
{"N":"KeyValue2"}},
            {"HashKeyElement": {"S":"KeyValue3"}, "RangeKeyElement":{"N":"KeyValue4"}},
            {"HashKeyElement": {"S":"KeyValue5"}, "RangeKeyElement":
{"N":"KeyValue6"}}],
        "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]}
        }
}
```

Name	Description
Responses	Table names and the respective item attributes from the tables. Type: Map
Table	The name of the table containing the items. The entry is simply a string specifying the table with no label. Type: String
Items	Container for the attribute names and values meeting the operation parameters. Type: Map of attribute names to and their data types and values.
ConsumedCapacityUnits	The number of read capacity units consumed, for each table. This value shows the number applied toward your provisioned throughput. Requests for non-existent items consume the minimum read capacity units, depending on the type of read. For more information see DynamoDB provisioned capacity mode.

Name	Description
	Type: Number
`UnprocessedKeys`	Contains an array of tables and their respective keys that were not processed with the current response, possibly due to reaching a limit on the response size. The `UnprocessedKeys` value is in the same form as a `RequestItems` parameter (so the value can be provided directly to a subsequent `BatchGetItem` operation). For more information, see the above `RequestItems` parameter. Type: Array
`UnprocessedKeys` : `Table`: `Keys`	The primary key attribute values that define the items and the attributes associated with the items. For more information about primary keys, see Primary key . Type: Array of attribute name-value pairs.
`UnprocessedKeys` : `Table`: `AttributesToGet`	Attribute names within the specified table. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array of attribute names.
`UnprocessedKeys` : `Table`: `ConsistentRead`	If set to `true`, then a consistent read is used for the specified table, otherwise an eventually consistent read is used. Type: Boolean.

Special errors

Error	Description
`ProvisionedThroughputExceededException`	Your maximum allowed provisioned throughput has been exceeded.

Examples

The following examples show an HTTP POST request and response using the BatchGetItem operation. For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

The following sample requests attributes from two different tables.

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1

BatchWriteItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

This operation enables you to put or delete several items across multiple tables in a single call.

To upload one item, you can use `PutItem`, and to delete one item, you can use `DeleteItem`. However, when you want to upload or delete large amounts of data, such as uploading large amounts of data from Amazon EMR (Amazon EMR) or migrating data from another database in to DynamoDB, `BatchWriteItem` offers an efficient alternative.

If you use languages such as Java, you can use threads to upload items in parallel. This adds complexity in your application to handle the threads. Other languages don't support threading. For example, if you are using PHP, you must upload or delete items one at a time. In both situations, `BatchWriteItem` provides an alternative where the specified put and delete operations are processed in parallel, giving you the power of the thread pool approach without having to introduce complexity in your application.

Note that each individual put and delete specified in a `BatchWriteItem` operation costs the same in terms of consumed capacity units. However, because `BatchWriteItem` performs the specified operations in parallel, you get lower latency. Delete operations on non-existent items consume 1 write capacity unit. For more information about consumed capacity units, see Working with tables and data in DynamoDB.

When using `BatchWriteItem`, note the following limitations:

- **Maximum operations in a single request—**You can specify a total of up to 25 put or delete operations; however, the total request size cannot exceed 1 MB (the HTTP payload).
- You can use the `BatchWriteItem` operation only to put and delete items. You cannot use it to update existing items.
- **Not an atomic operation—**Individual operations specified in a `BatchWriteItem` are atomic; however `BatchWriteItem` as a whole is a "best-effort" operation and not an atomic operation. That is, in a `BatchWriteItem` request, some operations might succeed and others might fail. The failed operations are returned in an `UnprocessedItems` field in the response. Some of these failures might be because you exceeded the provisioned throughput configured for the table or a transient failure such as a network error. You can investigate and optionally resend the requests. Typically, you call `BatchWriteItem` in a loop and in each iteration check for unprocessed items, and submit a new `BatchWriteItem` request with those unprocessed items.
- **Does not return any items—**The `BatchWriteItem` is designed for uploading large amounts of data efficiently. It does not provide some of the sophistication offered by `PutItem` and `DeleteItem`. For example, `DeleteItem` supports the `ReturnValues` field in your request body to request the deleted item in the response. The `BatchWriteItem` operation does not return any items in the response.
- Unlike `PutItem` and `DeleteItem`, `BatchWriteItem` does not allow you to specify conditions on individual write requests in the operation.
- Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that have empty values will be rejected with a `ValidationException`.

DynamoDB rejects the entire batch write operation if any one of the following is true:

- If one or more tables specified in the `BatchWriteItem` request does not exist.
- If primary key attributes specified on an item in the request does not match the corresponding table's primary key schema.
- If you try to perform multiple operations on the same item in the same `BatchWriteItem` request. For example, you cannot put and delete the same item in the same `BatchWriteItem` request.
- If the total request size exceeds the 1 MB request size (the HTTP payload) limit.
- If any individual item in a batch exceeds the 64 KB item size limit.

Requests

Syntax

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{
  "RequestItems" :  RequestItems
}

RequestItems
{
     "TableName1" :  [ Request, Request, ... ],
     "TableName2" :  [ Request, Request, ... ],
     ...
}

Request ::=
  PutRequest | DeleteRequest

PutRequest ::=
{
  "PutRequest" : {
     "Item" : {
        "Attribute-Name1" : Attribute-Value,
```

```
        "Attribute-Name2" : Attribute-Value,
         ...
     }
  }
}

DeleteRequest ::=
{
   "DeleteRequest" : {
      "Key" : PrimaryKey-Value
   }
}

PrimaryKey-Value ::= HashTypePK | HashAndRangeTypePK

HashTypePK ::=
{
   "HashKeyElement" : Attribute-Value
}

HashAndRangeTypePK
{
   "HashKeyElement" : Attribute-Value,
   "RangeKeyElement" : Attribute-Value,
}

Attribute-Value ::= String | Numeric| Binary | StringSet | NumericSet | BinarySet

Numeric ::=
{
   "N": "Number"
}

String ::=
{
   "S": "String"
}

Binary ::=
{
    "B": "Base64 encoded binary data"
}
```

```
StringSet ::=
{
   "SS": [ "String1", "String2", ... ]
}

NumberSet ::=
{
   "NS": [ "Number1", "Number2", ... ]
}

BinarySet ::=
{
   "BS": [ "Binary1", "Binary2", ... ]
}
```

In the request body, the `RequestItems` JSON object describes the operations that you want to perform. The operations are grouped by tables. You can use `BatchWriteItem` to update or delete several items across multiple tables. For each specific write request, you must identify the type of request (`PutItem`, `DeleteItem`) followed by detail information about the operation.

- For a `PutRequest`, you provide the item, that is, a list of attributes and their values.
- For a `DeleteRequest`, you provide the primary key name and value.

Responses

Syntax

The following is the syntax of the JSON body returned in the response.

```
{
  "Responses" :         ConsumedCapacityUnitsByTable
  "UnprocessedItems" :  RequestItems
}

ConsumedCapacityUnitsByTable
{
    "TableName1" : { "ConsumedCapacityUnits", : NumericValue },
    "TableName2" : { "ConsumedCapacityUnits", : NumericValue },
     ...
}

RequestItems
```

```
This syntax is identical to the one described in the JSON syntax in the request.
```

Special errors

No errors specific to this operation.

Examples

The following example shows an HTTP POST request and the response of a `BatchWriteItem` operation. The request specifies the following operations on the Reply and the Thread tables:

- Put an item and delete an item from the Reply table
- Put an item into the Thread table

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{
  "RequestItems":{
    "Reply":[
      {
        "PutRequest":{
          "Item":{
            "ReplyDateTime":{
              "S":"2012-04-03T11:04:47.034Z"
            },
            "Id":{
              "S":"DynamoDB#DynamoDB Thread 5"
            }
          }
        }
      },
      {
        "DeleteRequest":{
          "Key":{
```

```
            "HashKeyElement":{
              "S":"DynamoDB#DynamoDB Thread 4"
            },
            "RangeKeyElement":{
              "S":"oops - accidental row"
            }
          }
        }
      }
    ],
    "Thread":[
      {
        "PutRequest":{
          "Item":{
            "ForumName":{
              "S":"DynamoDB"
            },
            "Subject":{
              "S":"DynamoDB Thread 5"
            }
          }
        }
      }
    ]
  }
}
```

Sample response

The following example response shows a put operation on both the Thread and Reply tables succeeded and a delete operation on the Reply table failed (for reasons such as throttling that is caused when you exceed the provisioned throughput on the table). Note the following in the JSON response:

- The `Responses` object shows one capacity unit was consumed on both the `Thread` and `Reply` tables as a result of the successful put operation on each of these tables.
- The `UnprocessedItems` object shows the unsuccessful delete operation on the `Reply` table. You can then issue a new `BatchWriteItem` call to address these unprocessed requests.

```
HTTP/1.1 200 OK
x-amzn-RequestId: G8M9ANLOE5QA26AEUHJKJE0ASBVV4KQNSO5AEMVJF66Q9ASUAAJG
```

```

            "DeleteRequest":{
               "Key":{
                  "HashKeyElement":{
                     "S":"DynamoDB#DynamoDB Thread 4"
                  },
                  "RangeKeyElement":{
                     "S":"oops - accidental row"
                  }
               }
            }
         }
      ]
   }
}
```

CreateTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

The `CreateTable` operation adds a new table to your account.

The table name must be unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-2.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data.

The `CreateTable` operation triggers an asynchronous workflow to begin creating the table. DynamoDB immediately returns the state of the table (`CREATING`) until the table is in the `ACTIVE` state. Once the table is in the `ACTIVE` state, you can perform data plane operations.

Use the DescribeTables operation to check the status of the table.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.CreateTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"AttributeName1","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"AttributeName2","AttributeType":"N"}},
    "ProvisionedThroughput":{"ReadCapacityUnits":5,"WriteCapacityUnits":10}
}
```

Name	Description	Required
`TableName`	The name of the table to create. Allowed characters are a-z, A-Z, 0-9, '_' (underscore),	Yes

Name	Description	Required
	'-' (dash), and '.' (dot). Names can be between 3 and 255 characters long. Type: String	
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). For more information about primary keys, see Primary key. Primary key element names can be between 1 and 255 characters long with no character restrictions. Possible values for the AttributeType are "S" (string), "N" (numeric), or "B" (binary). Type: Map of HashKeyElement, or HashKeyElement and RangeKeyElement for a composite primary key.	Yes

Name	Description	Required
`ProvisionedThroughput`	New throughput for the specified table, consisting of values for `ReadCapacityUnits` and `WriteCapacityUnits`. For details, see DynamoDB provisioned capacity mode. **Note** For current maximum/minimum values, see Quotas in Amazon DynamoDB. Type: Array	Yes

Name	Description	Required
`ProvisionedThroughput : ReadCapacityUnits`	Sets the minimum number of consistent `ReadCapacityUnits` consumed per second for the specified table before DynamoDB balances the load with other operations. Eventually consistent read operations require less effort than a consistent read operation, so a setting of 50 consistent `ReadCapacityUnits` per second provides 100 eventually consistent `ReadCapacityUnits` per second. Type: Number	Yes
`ProvisionedThroughput : WriteCapacityUnits`	Sets the minimum number of `WriteCapacityUnits` consumed per second for the specified table before DynamoDB balances the load with other operations. Type: Number	Yes

Responses

    "KeySchema":
        {"HashKeyElement":{"AttributeName":"AttributeName1","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"AttributeName2","AttributeType":"N"}},
    "ProvisionedThroughput":{"ReadCapacityUnits":5,"WriteCapacityUnits":10},
    "TableName":"Table1",
    "TableStatus":"CREATING"
    }
}
```

Name	Description
TableDescription	A container for the table properties.
CreationDateTime	Date when the table was created in UNIX epoch time. Type: Number
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). For more information about primary keys, see Primary key . Type: Map of HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.
ProvisionedThroughput	Throughput for the specified table, consisting of values for ReadCapacityUnits and

Name	Description
	WriteCapacityUnits . See DynamoDB provisioned capacity mode. Type: Array
ProvisionedThroughput :ReadCapacityUnits	The minimum number of ReadCapacityUnits consumed per second before DynamoDB. balances the load with other operations Type: Number
ProvisionedThroughput :WriteCapacityUnits	The minimum number of ReadCapacityUnits consumed per second before WriteCapacityUnits . balances the load with other operations Type: Number
TableName	The name of the created table. Type: String
TableStatus	The current state of the table (CREATING). Once the table is in the ACTIVE state, you can put data in it. Use the DescribeTables API to check the status of the table. Type: String

Special errors

Error	Description
`ResourceInUseException`	Attempt to recreate an already existing table.
`LimitExceededException`	The number of simultaneous table requests (cumulative number of tables in the `CREATING`, `DELETING` or `UPDATING` state) exceeds the maximum allowed. **Note** For current maximum/minimum values, see Quotas in Amazon DynamoDB. .

Examples

The following example creates a table with a composite primary key containing a string and a number. For examples using the AWS SDK, see Working with tables and data in DynamoDB.

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1

DeleteItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Deletes a single item in a table by primary key. You can perform a conditional delete operation that deletes the item if it exists, or if it has an expected attribute value.

Note

If you specify `DeleteItem` without attributes or values, all the attributes for the item are deleted.
Unless you specify conditions, the `DeleteItem` is an idempotent operation; running it multiple times on the same item or attribute does *not* result in an error response.
Conditional deletes are useful for only deleting items and attributes if specific conditions are met. If the conditions are met, DynamoDB performs the delete. Otherwise, the item is not deleted.
You can perform the expected conditional check on one attribute per operation.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DeleteItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Key":
        {"HashKeyElement":{"S":"AttributeValue1"},"RangeKeyElement":
{"N":"AttributeValue2"}},
    "Expected":{"AttributeName3":{"Value":{"S":"AttributeValue3"}}},
    "ReturnValues":"ALL_OLD"}
}
```

Name	Description	Required
`TableName`	The name of the table containing the item to delete. Type: String	Yes
`Key`	The primary key that defines the item. For more informati	Yes

Name	Description	Required
	on about primary keys, see Primary key. Type: Map of `HashKeyElement` to its value and `RangeKeyElement` to its value.	
`Expected`	Designates an attribute for a conditional delete. The `Expected` parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute has a particular value before deleting it. Type: Map of attribute names.	No
`Expected:AttributeName`	The name of the attribute for the conditional put. Type: String	No

Name	Description	Required

`Expected:AttributeName: ExpectedAttributeValue`	Use this parameter to specify whether or not a value already exists for the attribute name-value pair.
	
	The following JSON notation deletes the item if the "Color" attribute doesn't exist for that item:
	
	`"Expected" : {"Color":{"Exists":false}}`
	
	The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before deleting the item:
	
	`"Expected" : {"Color":{"Exists":true},{"Value":{"S":"Yellow"}}}`
	
	By default, if you use the `Expected` parameter and provide a `Value`, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify `{"Exists":true}`, because it is implied. You can shorten the request to:
	
	`"Expected" :`
		No

Name	Description	Required
	`{"Color":{"Value":{"S":"Yellow"}}}` **Note** If you specify `{"Exists":true}` without an attribute value to check, DynamoDB returns an error.	
`ReturnValues`	Use this parameter if you want to get the attribute name-value pairs before they were deleted. Possible parameter values are `NONE` (default) or `ALL_OLD`. If `ALL_OLD` is specified, the content of the old item is returned. If this parameter is not provided or is `NONE`, nothing is returned. Type: String	No

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: CSOC7TJPLR0OOKIRLGOHVAICUFVV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
content-length: 353
Date: Tue, 12 Jul 2011 21:31:03 GMT
```

```
{"Attributes":
    {"AttributeName3":{"SS":["AttributeValue3","AttributeValue4","AttributeValue5"]},
    "AttributeName2":{"S":"AttributeValue2"},
    "AttributeName1":{"N":"AttributeValue1"}
    },
"ConsumedCapacityUnits":1
}
```

Name	Description
`Attributes`	If the `ReturnValues` parameter is provided as `ALL_OLD` in the request, DynamoDB returns an array of attribute name-value pairs (essentially, the deleted item). Otherwise, the response contains an empty set. Type: Array of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of write capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. Delete requests on non-existent items consume 1 write capacity unit. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ConditionalCheckFailedException`	Conditional check failed. An expected attribute value was not found.

Examples

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1

- PutItem

DeleteTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

The `DeleteTable` operation deletes a table and all of its items. After a `DeleteTable` request, the specified table is in the `DELETING` state until DynamoDB completes the deletion. If the table is in the `ACTIVE` state, you can delete it. If a table is in `CREATING` or `UPDATING` states, then DynamoDB returns a `ResourceInUseException` error. If the specified table does not exist, DynamoDB returns a `ResourceNotFoundException`. If table is already in the `DELETING` state, no error is returned.

Note

DynamoDB might continue to accept data plane operation requests, such as `GetItem` and `PutItem`, on a table in the `DELETING` state until the table deletion is complete.

Tables are unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-1.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data; deleting one does not delete the other.

Use the DescribeTables operation to check the status of the table.

Requests

Syntax

```
// This header is abbreviated.
```

```
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DeleteTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1"}
```

Name	Description	Required
TableName	The name of the table to delete. Type: String	Yes

Responses

Syntax

Date: Sun, 14 Aug 2011 22:56:22 GMT

{"TableDescription":
    {"CreationDateTime":1.313362508446E9,
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"user","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"time","AttributeType":"N"}},
    "ProvisionedThroughput":{"ReadCapacityUnits":10,"WriteCapacityUnits":10},
    "TableName":"Table1",
    "TableStatus":"DELETING"
    }
}
```

Name	Description
TableDescription	A container for the table properties.
CreationDateTime	Date when the table was created.

Name	Description
	Type: Number
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). For more information about primary keys, see Primary key. Type: Map of HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.
ProvisionedThroughput	Throughput for the specified table, consisting of values for ReadCapacityUnits and WriteCapacityUnits . See DynamoDB provisioned capacity mode.
ProvisionedThroughput : ReadCapacityUnits	The minimum number of ReadCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations. Type: Number
ProvisionedThroughput :WriteCapacityUnits	The minimum number of WriteCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations. Type: Number
TableName	The name of the deleted table. Type: String

Name	Description
TableStatus	The current state of the table (DELETING). Once the table is deleted, subsequent requests for the table return resource not found. Use the DescribeTables operation to check the status of the table. Type: String

Special errors

Error	Description
ResourceInUseException	Table is in state CREATING or UPDATING and can't be deleted.

Examples

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DeleteTable
content-type: application/x-amz-json-1.0
content-length: 40

{"TableName":"favorite-movies-table"}
```

Sample response

```
HTTP/1.1 200 OK
x-amzn-RequestId: 4HONCKIVH1BFUDQ1U68CTG3N27VV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
content-length: 160
```

```
Date: Sun, 14 Aug 2011 17:20:03 GMT

{"TableDescription":
    {"CreationDateTime":1.313362508446E9,
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"name","AttributeType":"S"}},
    "TableName":"favorite-movies-table",
    "TableStatus":"DELETING"
}
```

DescribeTables

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Returns information about the table, including the current status of the table, the primary key schema and when the table was created. DescribeTable results are eventually consistent. If you use DescribeTable too early in the process of creating a table, DynamoDB returns a `ResourceNotFoundException`. If you use DescribeTable too early in the process of updating a table, the new values might not be immediately available.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
```

```
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DescribeTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1"}
```

Name	Description	Required
TableName	The name of the table to describe. Type: String	Yes

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
Content-Length: 543

{"Table":
    {"CreationDateTime":1.309988345372E9,
    ItemCount:1,
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"AttributeName1","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"AttributeName2","AttributeType":"N"}},
    "ProvisionedThroughput":{"LastIncreaseDateTime": Date, "LastDecreaseDateTime":
 Date, "ReadCapacityUnits":10,"WriteCapacityUnits":10},
    "TableName":"Table1",
    "TableSizeBytes":1,
    "TableStatus":"ACTIVE"
    }
}
```

Name	Description
Table	Container for the table being described.

Name	Description
	Type: String
`CreationDateTime`	Date when the table was created in UNIX epoch time.
`ItemCount`	Number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value. Type: Number
`KeySchema`	The primary key (simple or composite) structure for the table. A name-value pair for the `HashKeyElement` is required, and a name-value pair for the `RangeKeyElement` is optional (only required for composite primary keys). The maximum hash key size is 2048 bytes. The maximum range key size is 1024 bytes. Both limits are enforced separatel y (i.e. you can have a combined hash + range 2048 + 1024 key). For more information about primary keys, see Primary key .
`ProvisionedThroughput`	Throughput for the specified table, consistin g of values for `LastIncreaseDateTime` (if applicable), `LastDecreaseDateTime` (if applicable), `ReadCapacityUnits` and `WriteCapacityUnits` . If the throughpu t for the table has never been increased or decreased, DynamoDB does not return values for those elements. See DynamoDB provision ed capacity mode. Type: Array

Name	Description
TableName	The name of the requested table. Type: String
TableSizeBytes	Total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value. Type: Number
TableStatus	The current state of the table (CREATING, ACTIVE, DELETING or UPDATING). Once the table is in the ACTIVE state, you can add data.

Special errors

No errors are specific to this operation.

Examples

The following examples show an HTTP POST request and response using the DescribeTable operation for a table named "comp-table". The table has a composite primary key.

Sample Request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DescribeTable
content-type: application/x-amz-json-1.0

{"TableName":"users"}
```

Sample response

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
```

```
content-type: application/x-amz-json-1.0
content-length: 543

{"Table":
    {"CreationDateTime":1.309988345372E9,
    "ItemCount":23,
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"user","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"time","AttributeType":"N"}},
    "ProvisionedThroughput":{"LastIncreaseDateTime": 1.309988345384E9,
 "ReadCapacityUnits":10,"WriteCapacityUnits":10},
    "TableName":"users",
    "TableSizeBytes":949,
    "TableStatus":"ACTIVE"
    }
}
```

GetItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

The `GetItem` operation returns a set of `Attributes` for an item that matches the primary key. If there is no matching item, `GetItem` does not return any data.

The `GetItem` operation provides an eventually consistent read by default. If eventually consistent reads are not acceptable for your application, use `ConsistentRead`. Although this operation

might take longer than a standard read, it always returns the last updated value. For more information, see DynamoDB read consistency.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.GetItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
  "Key":
  {"HashKeyElement": {"S":"AttributeValue1"},
  "RangeKeyElement": {"N":"AttributeValue2"}
 },
 "AttributesToGet":["AttributeName3","AttributeName4"],
 "ConsistentRead":Boolean
}
```

Name	Description	Required
`TableName`	The name of the table containing the requested item. Type: String	Yes
`Key`	The primary key values that define the item. For more information about primary keys, see Primary key. Type: Map of `HashKeyElement` to its value and `RangeKeyElement` to its value.	Yes

Name	Description	Required
AttributesToGet	Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
ConsistentRead	If set to true, then a consistent read is issued, otherwise eventually consistent is used. Type: Boolean	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 144

{"Item":{
 "AttributeName3":{"S":"AttributeValue3"},
 "AttributeName4":{"N":"AttributeValue4"},
 "AttributeName5":{"B":"dmFsdWU="}
 },
"ConsumedCapacityUnits": 0.5
}
```

Name	Description
Item	Contains the requested attributes.

Name	Description
	Type: Map of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of read capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. Requests for non-existent items consume the minimum read capacity units, depending on the type of read. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

No errors specific to this operation.

Examples

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.GetItem
content-type: application/x-amz-json-1.0

{"TableName":"comptable",
 "Key":
  {"HashKeyElement":{"S":"Julie"},
  "RangeKeyElement":{"N":"1307654345"}},
 "AttributesToGet":["status","friends"],
 "ConsistentRead":true
}
```

Sample response

Notice the ConsumedCapacityUnits value is 1, because the optional parameter `ConsistentRead` is set to `true`. If `ConsistentRead` is set to `false` (or not specified) for the same request, the response is eventually consistent and the ConsumedCapacityUnits value would be 0.5.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 72

{"Item":
 {"friends":{"SS":["Lynda, Aaron"]},
 "status":{"S":"online"}
 },
"ConsumedCapacityUnits": 1
}
```

ListTables

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Returns an array of all the tables associated with the current account and endpoint.

Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-east-1.amazonaws.com, they are completely independent and do not share any data. The ListTables operation returns all of the table names associated with the account making the request, for the endpoint that receives the request.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.ListTables
content-type: application/x-amz-json-1.0

{"ExclusiveStartTableName":"Table1","Limit":3}
```

The ListTables operation, by default, requests all of the table names associated with the account making the request, for the endpoint that receives the request.

Name	Description	Required
`Limit`	A number of maximum table names to return. Type: Integer	No
`ExclusiveStartTableName`	The name of the table that starts the list. If you already ran a ListTables operation and received an `LastEvaluatedTableName` value in the response, use that value here to continue the list. Type: String	No

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: S1LEK2DPQP8OJNHVHL8OU2M7KRVV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
```

```
content-length: 81
Date: Fri, 21 Oct 2011 20:35:38 GMT

{"TableNames":["Table1","Table2","Table3"], "LastEvaluatedTableName":"Table3"}
```

Name	Description
`TableNames`	The names of the tables associated with the current account at the current endpoint. Type: Array
`LastEvaluatedTableName`	The name of the last table in the current list, only if some tables for the account and endpoint have not been returned. This value does not exist in a response if all table names are already returned. Use this value as the `ExclusiveStartTableName` in a new request to continue the list until all the table names are returned. Type: String

Special errors

No errors are specific to this operation.

Examples

The following examples show an HTTP POST request and response using the ListTables operation.

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.ListTables
content-type: application/x-amz-json-1.0
```

```
{"ExclusiveStartTableName":"comp2","Limit":3}
```

Sample response

```
HTTP/1.1 200 OK
x-amzn-RequestId: S1LEK2DPQP8OJNHVHL8OU2M7KRVV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
content-length: 81
Date: Fri, 21 Oct 2011 20:35:38 GMT

{"LastEvaluatedTableName":"comp5","TableNames":["comp3","comp4","comp5"]}
```

PutItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Creates a new item, or replaces an old item with a new item (including all the attributes). If an item already exists in the specified table with the same primary key, the new item completely replaces the existing item. You can perform a conditional put (insert a new item if one with the specified primary key doesn't exist), or replace an existing item if it has certain attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException`.

> **Note**
>
> To ensure that a new item does not replace an existing item, use a conditional put operation with `Exists` set to `false` for the primary key attribute, or attributes.

For more information about using `PutItem`, see Working with items and attributes in DynamoDB.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.PutItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Item":{
        "AttributeName1":{"S":"AttributeValue1"},
        "AttributeName2":{"N":"AttributeValue2"},
        "AttributeName5":{"B":"dmFsdWU="}
    },
    "Expected":{"AttributeName3":{"Value": {"S":"AttributeValue"}, "Exists":Boolean}},
    "ReturnValues":"ReturnValuesConstant"}
```

Name	Description	Required
`TableName`	The name of the table to contain the item. Type: String	Yes
`Item`	A map of the attributes for the item, and must include the primary key values that define the item. Other attribute name-value pairs can be provided for the item.	Yes

Name	Description	Required
	For more information about primary keys, see Primary key. Type: Map of attribute names to attribute values.	
`Expected`	Designates an attribute for a conditional put. The `Expected` parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute value already exists; or if the attribute value exists and has a particular value before changing it. Type: Map of an attribute names to an attribute value, and whether it exists.	No
`Expected:AttributeName`	The name of the attribute for the conditional put. Type: String	No

Name	Description	Required

`Expected:AttributeName: ExpectedAttributeValue`	Use this parameter to specify whether or not a value already exists for the attribute name-value pair.
	
	The following JSON notation replaces the item if the "Color" attribute doesn't already exist for that item:
	
	`"Expected" : {"Color":{"Exists":false}}`
	
	The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before replacing the item:
	
	`"Expected" : {"Color":{"Exists":true,{"Value":{"S":"Yellow"}}}}`
	
	By default, if you use the `Expected` parameter and provide a `Value`, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify `{"Exists":true}`, because it is implied. You can shorten the request to:
	
	`"Expected" :`
		No

Name	Description	Required
	`{"Color":{"Value":{"S":"Yellow"}}}` **Note** If you specify `{"Exists":true}` without an attribute value to check, DynamoDB returns an error.	
`ReturnValues`	Use this parameter if you want to get the attribute name-value pairs before they were updated with the `PutItem` request. Possible parameter values are `NONE` (default) or `ALL_OLD`. If `ALL_OLD` is specified, and `PutItem` overwrote an attribute name-value pair, the content of the old item is returned. If this parameter is not provided or is `NONE`, nothing is returned. Type: String	No

Responses

Syntax

The following syntax example assumes the request specified a `ReturnValues` parameter of `ALL_OLD`; otherwise, the response has only the `ConsumedCapacityUnits` element.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 85

{"Attributes":
 {"AttributeName3":{"S":"AttributeValue3"},
 "AttributeName2":{"SS":"AttributeValue2"},
 "AttributeName1":{"SS":"AttributeValue1"},
 },
"ConsumedCapacityUnits":1
}
```

Name	Description
`Attributes`	Attribute values before the put operation, but only if the `ReturnValues` parameter is specified as `ALL_OLD` in the request. Type: Map of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of write capacity units consumed by the operation. This value shows the number applied toward your provision ed throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ConditionalCheckFailedException`	Conditional check failed. An expected attribute value was not found.
`ResourceNotFoundException`	The specified item or attribute was not found.

Examples

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.PutItem
content-type: application/x-amz-json-1.0

{"TableName":"comp5",
 "Item":
  {"time":{"N":"300"},
  "feeling":{"S":"not surprised"},
  "user":{"S":"Riley"}
  },
 "Expected":
  {"feeling":{"Value":{"S":"surprised"},"Exists":true}}
 "ReturnValues":"ALL_OLD"
}
```

Sample response

```
HTTP/1.1 200
x-amzn-RequestId: 8952fa74-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 84

{"Attributes":
 {"feeling":{"S":"surprised"},
 "time":{"N":"300"},
 "user":{"S":"Riley"}},
"ConsumedCapacityUnits":1
}
```

Query

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

A `Query` operation gets the values of one or more items and their attributes by primary key (`Query` is only available for hash-and-range primary key tables). You must provide a specific `HashKeyValue`, and can narrow the scope of the query using comparison operators on the `RangeKeyValue` of the primary key. Use the `ScanIndexForward` parameter to get results in forward or reverse order by range key.

Queries that do not return results consume the minimum read capacity units according to the type of read.

> **Note**
>
> If the total number of items meeting the query parameters exceeds the 1MB limit, the query stops and results are returned to the user with a `LastEvaluatedKey` to continue the query in a subsequent operation. Unlike a Scan operation, a Query operation never returns an empty result set *and* a `LastEvaluatedKey`. The `LastEvaluatedKey` is only provided if the results exceed 1MB, or if you have used the `Limit` parameter.
> The result can be set for a consistent read using the `ConsistentRead` parameter.

Requests

Syntax

```
// This header is abbreviated.
```

```
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.Query
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
 "Limit":2,
 "ConsistentRead":true,
 "HashKeyValue":{"S":"AttributeValue1":},
 "RangeKeyCondition": {"AttributeValueList":
[{"N":"AttributeValue2"}],"ComparisonOperator":"GT"}
 "ScanIndexForward":true,
 "ExclusiveStartKey":{
  "HashKeyElement":{"S":"AttributeName1"},
  "RangeKeyElement":{"N":"AttributeName2"}
 },
    "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]},
}
```

Name	Description	Required
TableName	The name of the table containing the requested items. Type: String	Yes
AttributesToGet	Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
Limit	The maximum number of items to return (not necessarily the number of matching items). If Dynamo	No

Name	Description	Required
	DB processes the number of items up to the limit while querying the table, it stops the query and returns the matching values up to that point, and a `LastEvaluatedKey` to apply in a subsequent operation to continue the query. Also, if the result set size exceeds 1MB before DynamoDB hits this limit, it stops the query and returns the matching values, and a `LastEvaluatedKey` to apply in a subsequent operation to continue the query. Type: Number	
`ConsistentRead`	If set to `true`, then a consistent read is issued, otherwise eventually consistent is used. Type: Boolean	No

Name	Description	Required
`Count`	If set to `true`, DynamoDB returns a total number of items that match the query parameters, instead of a list of the matching items and their attributes. You can apply the `Limit` parameter to count-only queries. Do not set `Count` to `true` while providing a list of `AttributesToGet` ; otherwise, DynamoDB returns a validation error. For more information, see Counting the items in the results. Type: Boolean	No
`HashKeyValue`	Attribute value of the hash component of the composite primary key. Type: String, Number, or Binary	Yes

Name	Description	Required
RangeKeyCondition	A container for the attribute values and comparison operators to use for the query. A query request does not require a RangeKeyCondition. If you provide only the HashKeyValue, DynamoDB returns all items with the specified hash key element value. Type: Map	No
RangeKeyCondition : AttributeValueList	The attribute values to evaluate for the query parameters. The AttributeValueList contains one attribute value, unless a BETWEEN comparison is specified. For the BETWEEN comparison, the AttributeValueList contains two attribute values. Type: A map of AttributeValue to a ComparisonOperator.	No

Name	Description	Required
`RangeKeyCondition : ComparisonOperator`	The criteria for evaluating the provided attributes, such as equals, greater-than, etc. The following are valid comparison operators for a Query operation. **Note** String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and aa is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values, for example when evaluating query expressions. Type: String or Binary	No

Name	Description	Required
	EQ : Equal. For EQ, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.	
	LE : Less than or equal. For LE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	LT : Less than. For LT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	GE : Greater than or equal. For GE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	GT : Greater than. For GT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	`BEGINS_WITH` : checks for a prefix. For `BEGINS_WITH` , `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).	

Name	Description	Required
	BETWEEN : Greater than, or equal to, the first value and less than, or equal to, the second value. For BETWEEN, AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.	

Name	Description	Required
ScanIndexForward	Specifies ascending or descending traversal of the index. DynamoDB returns results reflecting the requested order determined by the range key: If the data type is Number, the results are returned in numeric order; otherwise, the traversal is based on ASCII character code values. Type: Boolean Default is true (ascending).	No
ExclusiveStartKey	Primary key of the item from which to continue an earlier query. An earlier query might provide this value as the LastEvaluatedKey if that query operation was interrupted before completing the query; either because of the result set size or the Limit parameter. The LastEvaluatedKey can be passed back in a new query request to continue the operation from that point. Type: HashKeyElement, or HashKeyElement and RangeKeyElement for a composite primary key.	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 308

{"Count":2,"Items":[{
    "AttributeName1":{"S":"AttributeValue1"},
    "AttributeName2":{"N":"AttributeValue2"},
    "AttributeName3":{"S":"AttributeValue3"}
    },{
    "AttributeName1":{"S":"AttributeValue3"},
    "AttributeName2":{"N":"AttributeValue4"},
    "AttributeName3":{"S":"AttributeValue3"},
    "AttributeName5":{"B":"dmFsdWU="}
}],
    "LastEvaluatedKey":{"HashKeyElement":{"AttributeValue3":"S"},
                        "RangeKeyElement":{"AttributeValue4":"N"}
     },
     "ConsumedCapacityUnits":1
}
```

Name	Description
`Items`	Item attributes meeting the query parameters. Type: Map of attribute names to and their data types and values.
`Count`	Number of items in the response. For more information, see Counting the items in the results. Type: Number
`LastEvaluatedKey`	Primary key of the item where the query operation stopped, inclusive of the previous result set. Use this value to start a new

Name	Description
	operation excluding this value in the new request. The `LastEvaluatedKey` is `null` when the entire query result set is complete (i.e. the operation processed the "last page"). Type: `HashKeyElement`, or `HashKeyElement` and `RangeKeyElement` for a composite primary key.
`ConsumedCapacityUnits`	The number of read capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ResourceNotFoundException`	The specified table was not found.

Examples

For examples using the AWS SDK, see Querying tables in DynamoDB.

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.Query
content-type: application/x-amz-json-1.0
```

```
{"TableName":"1-hash-rangetable",

- Scan

Scan

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

The `Scan` operation returns one or more items and its attributes by performing a full scan of a table. Provide a `ScanFilter` to get more specific results.

Note

If the total number of scanned items exceeds the 1MB limit, the scan stops and results are returned to the user with a `LastEvaluatedKey` to continue the scan in a subsequent operation. The results also include the number of items exceeding the limit. A scan can result in no table data meeting the filter criteria.
The result set is eventually consistent.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.Scan
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Limit": 2,
    "ScanFilter":{
        "AttributeName1":{"AttributeValueList":
[{"S":"AttributeValue"}],"ComparisonOperator":"EQ"}
    },
    "ExclusiveStartKey":{
        "HashKeyElement":{"S":"AttributeName1"},
        "RangeKeyElement":{"N":"AttributeName2"}
    },
    "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]},
}
```

Name	Description	Required
`TableName`	The name of the table containing the requested items. Type: String	Yes

Name	Description	Required
`AttributesToGet`	Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
`Limit`	The maximum number of items to evaluate (not necessarily the number of matching items). If DynamoDB processes the number of items up to the limit while processing the results, it stops and returns the matching values up to that point, and a `LastEvaluatedKey` to apply in a subsequent operation to continue retrieving items. Also, if the scanned data set size exceeds 1MB before DynamoDB reaches this limit, it stops the scan and returns the matching values up to the limit, and a `LastEvaluatedKey` to apply in a subsequent operation to continue the scan. Type: Number	No

Name	Description	Required
`Count`	If set to `true`, DynamoDB returns a total number of items for the Scan operation, even if the operation has no matching items for the assig ned filter. You can apply the Limit parameter to count-onl y scans. Do not set `Count` to `true` while providing a list of `AttributesToGet` , otherwise DynamoDB returns a validation error. For more information, see Counting the items in the results. Type: Boolean	No
`ScanFilter`	Evaluates the scan results and returns only the desired values. Multiple condition s are treated as "AND" operations: all conditions must be met to be included in the results. Type: A map of attribute names to values with comparison operators.	No

Name	Description	Required
`ScanFilter :AttributeValueList`	The values and conditions to evaluate the scan results for the filter. Type: A map of `AttributeValue` to a `Condition` .	No

Name	Description	Required
`ScanFilter : ComparisonOperator`	The criteria for evaluating the provided attributes, such as equals, greater-than, etc. The following are valid comparison operators for a scan operation. **Note** String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and aa is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values, for example when evaluating query expressions. Type: String or Binary	No

Name	Description	Required
	EQ : Equal. For EQ, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.	
	NE : Not Equal. For NE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	LE : Less than or equal. For LE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	LT : Less than. For LT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	GE : Greater than or equal. For GE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	GT : Greater than. For GT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	NOT_NULL : Attribute exists.	
	NULL : Attribute does not exist.	
	CONTAINS : checks for a subsequence, or value in a set. For CONTAINS, AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operation checks for a substring match. If the target attribute of the comparison is Binary, then the operation looks for a subsequence of the target th at matches the input. If the target attribute of the compa rison is a set ("SS", "NS", or "BS"), then the operation checks for a member of the set (not as a substring).	

Name	Description	Required
	`NOT_CONTAINS` : checks for absence of a subsequence, or absence of a value in a set. For `NOT_CONTAINS` , `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operation checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operation checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operation checks for the absence of a member of the set (not as a substring).	

Name	Description	Required
	BEGINS_WITH : checks for a prefix. For BEGINS_WITH , AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).	
	IN : checks for exact matches. For IN, AttributeValueList can contain more than one AttributeValue of type String, Number, or Binary (not a set). The target attribute of the comparison must be of the same type and exact value to match. A String never matches a String set.	

Name	Description	Required
	BETWEEN : Greater than, or equal to, the first value and less than, or equal to, the second value. For BETWEEN, AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.	

Name	Description	Required
ExclusiveStartKey	Primary key of the item from which to continue an earlier scan. An earlier scan might provide this value if that scan operation was interrupted before scanning the entire table; either because of the result set size or the Limit parameter. The LastEvaluatedKey can be passed back in a new scan request to continue the operation from that point. Type: HashKeyElement, or HashKeyElement and RangeKeyElement for a composite primary key.	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 229

        "RangeKeyElement":{"N":"AttributeName2"},
    "ConsumedCapacityUnits":1,
    "ScannedCount":2}
}
```

Name	Description
`Items`	Container for the attributes meeting the operation parameters. Type: Map of attribute names to and their data types and values.
`Count`	Number of items in the response. For more information, see Counting the items in the results. Type: Number
`ScannedCount`	Number of items in the complete scan before any filters are applied. A high `ScannedCount` value with few, or no, `Count` results indicates an inefficient `Scan` operation. For more information, see Counting the items in the results. Type: Number
`LastEvaluatedKey`	Primary key of the item where the scan operation stopped. Provide this value in a subsequent scan operation to continue the operation from that point. The `LastEvaluatedKey` is `null` when the entire scan result set is complete (i.e. the operation processed the “last page”).

Name	Description
ConsumedCapacityUnits	The number of read capacity units consumed by the operation. This value shows the number applied toward your provision ed throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
ResourceNotFoundException	The specified table was not found.

UpdateItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Edits an existing item's attributes. You can perform a conditional update (insert a new attribute name-value pair if it doesn't exist, or replace an existing name-value pair if it has certain expected attribute values).

> **Note**
>
> You cannot update the primary key attributes using UpdateItem. Instead, delete the item and use PutItem to create a new item with new attributes.

The UpdateItem operation includes an `Action` parameter, which defines how to perform the update. You can put, delete, or add attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException`.

If an existing item has the specified primary key:

- **PUT—** Adds the specified attribute. If the attribute exists, it is replaced by the new value.
- **DELETE—** If no value is specified, this removes the attribute and its value. If a set of values is specified, then the values in the specified set are removed from the old set. So if the attribute value contains [a,b,c] and the delete action contains [a,c], then the final attribute value is [b]. The type of the specified value must match the existing value type. Specifying an empty set is not valid.
- **ADD—** Only use the add action for numbers or if the target attribute is a set (including string sets). ADD does not work if the target attribute is a single string value or a scalar binary value. The specified value is added to a numeric value (incrementing or decrementing the existing numeric value) or added as an additional value in a string set. If a set of values is specified, the values are added to the existing set. For example if the original set is [1,2] and supplied value is [3], then after the add operation the set is [1,2,3], not [4,5]. An error occurs if an Add action is specified for a set attribute and the attribute type specified does not match the existing set type.

  If you use ADD for an attribute that does not exist, the attribute and its values are added to the item.

If no item matches the specified primary key:

- **PUT—** Creates a new item with specified primary key. Then adds the specified attribute.
- **DELETE—** Nothing happens.

- **ADD—** Creates an item with supplied primary key and number (or set of numbers) for the attribute value. Not valid for a string or a binary type.

> **Note**
>
> If you use ADD to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses `0` as the initial value. Also, if you update an item using ADD to increment or decrement a number value for an attribute that doesn't exist before the update (but the item does) DynamoDB uses `0` as the initial value. For example, you use ADD to add `+3` to an attribute that did not exist before the update. DynamoDB uses `0` for the initial value, and the value after the update is `3`.

For more information about using this operation, see Working with items and attributes in DynamoDB.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.UpdateItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Key":
        {"HashKeyElement":{"S":"AttributeValue1"},
        "RangeKeyElement":{"N":"AttributeValue2"}},
    "AttributeUpdates":{"AttributeName3":{"Value":
{"S":"AttributeValue3_New"},"Action":"PUT"}},
    "Expected":{"AttributeName3":{"Value":{"S":"AttributeValue3_Current"}}},
    "ReturnValues":"ReturnValuesConstant"
}
```

Name	Description	Required
`TableName`	The name of the table containing the item to update. Type: String	Yes
`Key`	The primary key that defines the item. For more informati on about primary keys, see Primary key. Type: Map of `HashKeyEl ement` to its value and `RangeKeyElement` to its value.	Yes
`AttributeUpdates`	Map of attribute name to the new value and action for the update. The attribute names specify the attributes to modify, and cannot contain any primary key attributes. Type: Map of attribute name, value, and an action for the attribute update.	
`Attribute Updates :Action`	Specifies how to perform the update. Possible values: `PUT` (default), `ADD` or `DELETE`. The semantics are explained in the UpdateItem descripti on. Type: String	No

Name	Description	Required
	Default: PUT	
`Expected`	Designates an attribute for a conditional update. The `Expected` parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute value already exists; or if the attribute value exists and has a particular value before changing it. Type: Map of attribute names.	No
`Expected:AttributeName`	The name of the attribute for the conditional put. Type: String	No

Name	Description	Required

`Expected:AttributeName: ExpectedAttributeValue`	Use this parameter to specify whether or not a value already exists for the attribute name-value pair.
	
	The following JSON notation updates the item if the "Color" attribute doesn't already exist for that item:
	
	`"Expected" : {"Color":{"Exists":false}}`
	
	The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before updating the item:
	
	`"Expected" : {"Color":{"Exists":true},{"Value":{"S":"Yellow"}}}`
	
	By default, if you use the `Expected` parameter and provide a `Value`, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify `{"Exists":true}`, because it is implied. You can shorten the request to:
	
	`"Expected" :`
		No

Name	Description	Required
	`{"Color":{"Value":{"S":"Yellow"}}}` **Note** If you specify `{"Exists":true}` without an attribute value to check, DynamoDB returns an error.	

Name	Description	Required
ReturnValues	Use this parameter if you want to get the attribute name-value pairs before they were updated with the UpdateItem request. Possible parameter values are NONE (default) or ALL_OLD, UPDATED_OLD , ALL_NEW or UPDATED_NEW . If ALL_OLD is specified, and UpdateItem overwrote an attribute name-value pair, the content of the old item is returned. If this parame ter is not provided or is NONE, nothing is returned . If ALL_NEW is specified, then all the attributes of the new version of the item are returned. If UPDATED_NEW is specified, then the new versions of only the updated attributes are returned. Type: String	No

Responses

Syntax

The following syntax example assumes the request specified a ReturnValues parameter of ALL_OLD; otherwise, the response has only the ConsumedCapacityUnits element.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
```

```
content-type: application/x-amz-json-1.0
content-length: 140

{"Attributes":{
 "AttributeName1":{"S":"AttributeValue1"},
 "AttributeName2":{"S":"AttributeValue2"},
 "AttributeName3":{"S":"AttributeValue3"},
 "AttributeName5":{"B":"dmFsdWU="}
 },
"ConsumedCapacityUnits":1
}
```

Name	Description
`Attributes`	A map of attribute name-value pairs, but only if the `ReturnValues` parameter is specified as something other than `NONE` in the request. Type: Map of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of write capacity units consumed by the operation. This value shows the number applied toward your provision ed throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ConditionalCheckFailedException`	Conditional check failed. Attribute ("+ name +") value is ("+ value +") but was expected ("+ expValue +")
`ResourceNotFoundExceptions`	The specified item or attribute was not found.

Examples

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

UpdateTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

Updates the provisioned throughput for the given table. Setting the throughput for a table helps you manage performance and is part of the provisioned throughput feature of DynamoDB. For more information, see DynamoDB provisioned capacity mode.

The provisioned throughput values can be upgraded or downgraded based on the maximums and minimums listed in Quotas in Amazon DynamoDB.

The table must be in the `ACTIVE` state for this operation to succeed. UpdateTable is an asynchronous operation; while executing the operation, the table is in the `UPDATING` state. While the table is in the `UPDATING` state, the table still has the provisioned throughput from before the call. The new provisioned throughput setting is in effect only when the table returns to the `ACTIVE` state after the UpdateTable operation.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.UpdateTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "ProvisionedThroughput":{"ReadCapacityUnits":5,"WriteCapacityUnits":15}
}
```

Name	Description	Required
TableName	The name of the table to update. Type: String	Yes
ProvisionedThroughput	New throughput for the specified table, consisting of values for ReadCapacityUnits and WriteCapacityUnits. See DynamoDB provisioned capacity mode. Type: Array	Yes
ProvisionedThroughput :ReadCapacityUnits	Sets the minimum number of consistent ReadCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations. Eventually consistent read operations require less effort than a consistent read operation, so a setting of 50 consistent ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second. Type: Number	Yes

Name	Description	Required
`ProvisionedThroughput :WriteCapacityUnits`	Sets the minimum number of `WriteCapacityUnits` consumed per second for the specified table before DynamoDB balances the load with other operations. Type: Number	Yes

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: CSOC7TJPLR0OOKIRLGOHVAICUFVV4KQNSO5AEMVJF66Q9ASUAAJG
Content-Type: application/json
Content-Length: 311
Date: Tue, 12 Jul 2011 21:31:03 GMT

{"TableDescription":
    {"CreationDateTime":1.321657838135E9,
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"AttributeValue1","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"AttributeValue2","AttributeType":"N"}},
    "ProvisionedThroughput":
        {"LastDecreaseDateTime":1.321661704489E9,
        "LastIncreaseDateTime":1.321663607695E9,
        "ReadCapacityUnits":5,
        "WriteCapacityUnits":10},
    "TableName":"Table1",
    "TableStatus":"UPDATING"}}
```

Name	Description
`CreationDateTime`	Date when the table was created.

Name	Description
	Type: Number
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). The maximum hash key size is 2048 bytes. The maximum range key size is 1024 bytes. Both limits are enforced separatel y (i.e. you can have a combined hash + range 2048 + 1024 key). For more information about primary keys, see Primary key. Type: Map of HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.
ProvisionedThroughput	Current throughput settings for the specified table, including values for LastIncre aseDateTime (if applicable), LastDecre aseDateTime (if applicable), Type: Array
TableName	The name of the updated table. Type: String
TableStatus	The current state of the table (CREATING, ACTIVE, DELETING or UPDATING), which should be UPDATING. Use the DescribeTables operationto check the status of the table. Type: String

Special errors

Error	Description
ResourceNotFoundException	The specified table was not found.
ResourceInUseException	The table is not in the ACTIVE state.

Examples

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.

Legacy DynamoDB conditional parameters

This document provides an overview of legacy conditional parameters in DynamoDB and recommends using the new expression parameters instead. It covers details on parameters like AttributesToGet, AttributeUpdates, ConditionalOperator, Expected, KeyConditions, QueryFilter, and ScanFilter, and provides examples of how to use the new expression parameters as replacements.

> **Important**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. Additionally, DynamoDB does not allow mixing legacy conditional parameters and expression parameters in a single call. For example, calling the `Query` operation with `AttributesToGet` and `ConditionExpression` will result in an error.

The following table shows the DynamoDB API operations that still support these legacy parameters, and which expression parameter to use instead. This table can be helpful if you are considering updating your applications so that they use expression parameters instead.

If you use this API operation ...	With these legacy parameters...	Use this expression parameter instead
`BatchGetItem`	`AttributesToGet`	`ProjectionExpression`
`DeleteItem`	`Expected`	`ConditionExpression`
`GetItem`	`AttributesToGet`	`ProjectionExpression`

If you use this API operation ...	With these legacy parameters...	Use this expression parameter instead
PutItem	Expected	ConditionExpression
Query	AttributesToGet	ProjectionExpression
	KeyConditions	KeyConditionExpression
	QueryFilter	FilterExpression
Scan	AttributesToGet	ProjectionExpression
	ScanFilter	FilterExpression
UpdateItem	AttributeUpdates	UpdateExpression
	Expected	ConditionExpression

The following sections provide more information about legacy conditional parameters.

Topics

- AttributesToGet (legacy)
- AttributeUpdates (legacy)
- ConditionalOperator (legacy)
- Expected (legacy)
- KeyConditions (legacy)
- QueryFilter (legacy)
- ScanFilter (legacy)
- Writing conditions with legacy parameters

AttributesToGet (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, Use *ProjectionExpression* instead.

The legacy conditional parameter `AttributesToGet` is an array of one or more attributes to retrieve from DynamoDB. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

`AttributesToGet` allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map.

Note that `AttributesToGet` has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

Use *ProjectionExpression* instead – Example

Suppose you wanted to retrieve an item from the *Music* table, but that you only wanted to return some of the attributes. You could use a `GetItem` request with an `AttributesToGet` parameter, as in this AWS CLI example:

```
aws dynamodb get-item \
    --table-name Music \
    --attributes-to-get '["Artist", "Genre"]' \
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }'
```

You can use a `ProjectionExpression` instead:

```
aws dynamodb get-item \
    --table-name Music \
    --projection-expression "Artist, Genre" \
```

```
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }'
```

AttributeUpdates (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *UpdateExpression* instead..

In an `UpdateItem` operation, the legacy conditional parameter `AttributeUpdates` contains the names of attributes to be modified, the action to perform on each, and the new value for each. If you are updating an attribute that is an index key attribute for any indexes on that table, the attribute type must match the index key type defined in the `AttributesDefinition` of the table description. You can use `UpdateItem` to update any non-key attributes.

Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException` exception.

Each `AttributeUpdates` element consists of an attribute name to modify, along with the following:

- `Value` - The new value, if applicable, for this attribute.
- `Action` - A value that specifies how to perform the update. This action is only valid for an existing attribute whose data type is Number or is a set; do not use ADD for other data types.

  If an item with the specified primary key is found in the table, the following values perform the following actions:

  - PUT - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.
  - `DELETE` - Removes the attribute and its value, if no value is specified for `DELETE`. The data type of the specified value must match the existing value's data type.

If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set `[a,b,c]` and the `DELETE` action specifies `[a,c]`, then the final attribute value is `[b]`. Specifying an empty set is an error.

- `ADD` - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of `ADD` depends on the data type of the attribute:
  - If the existing attribute is a number, and if `Value` is also a number, then `Value` is mathematically added to the existing attribute. If `Value` is a negative number, then it is subtracted from the existing attribute.

    > **Note**
    >
    > If you use `ADD` to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses 0 as the initial value.
    > Similarly, if you use `ADD` for an existing item to increment or decrement an attribute value that doesn't exist before the update, DynamoDB uses `0` as the initial value. For example, suppose that the item you want to update doesn't have an attribute named *itemcount*, but you decide to `ADD` the number `3` to this attribute anyway. DynamoDB will create the *itemcount* attribute, set its initial value to `0`, and finally add `3` to it. The result will be a new *itemcount* attribute, with a value of `3`.

  - If the existing data type is a set, and if `Value` is also a set, then `Value` is appended to the existing set. For example, if the attribute value is the set `[1,2]`, and the `ADD` action specified `[3]`, then the final attribute value is `[1,2,3]`. An error occurs if an `ADD` action is specified for a set attribute and the attribute type specified does not match the existing set type.

    Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, `Value` must also be a set of strings.

If no item with the specified key is found in the table, the following values perform the following actions:

- `PUT` - Causes DynamoDB to create a new item with the specified primary key, and then adds the attribute.
- `DELETE` - Nothing happens, because attributes cannot be deleted from a nonexistent item. The operation succeeds, but DynamoDB does not create a new item.
- `ADD` - Causes DynamoDB to create an item with the supplied primary key and number (or set of numbers) for the attribute value. The only data types allowed are Number and Number Set.

If you provide any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table's attribute definition.

Use *UpdateExpression* instead – Example

Suppose you wanted to modify an item in the *Music* table. You could use an `UpdateItem` request with an `AttributeUpdates` parameter, as in this AWS CLI example:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "SongTitle": {"S":"Call Me Today"},
        "Artist": {"S":"No One You Know"}
    }' \
    --attribute-updates '{
        "Genre": {
            "Action": "PUT",
            "Value": {"S":"Rock"}
        }
    }'
```

You can use a `UpdateExpression` instead:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "SongTitle": {"S":"Call Me Today"},
        "Artist": {"S":"No One You Know"}
    }' \
    --update-expression 'SET Genre = :g' \
    --expression-attribute-values '{
        ":g": {"S":"Rock"}
    }'
```

ConditionalOperator (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB.

The legacy conditional parameter `ConditionalOperator` is a logical operator used to apply to the conditions in a `Expected`, `QueryFilter` or `ScanFilter` map:

- AND - If all of the conditions evaluate to true, then the entire map evaluates to true.
- OR - If at least one of the conditions evaluates to true, then the entire map evaluates to true.

If you omit `ConditionalOperator`, then `AND` is the default.

The operation will succeed only if the entire map evaluates to true.

> **Note**
>
> This parameter does not support attributes of type List or Map.

Expected (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *ConditionExpression* instead..

The legacy conditional parameter `Expected` is a conditional block for an `UpdateItem` operation. `Expected` is a map of attribute/condition pairs. Each element of the map consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each `Expected` element, the result of the evaluation is either true or false.

If you specify more than one element in the `Expected` map, then by default all of the conditions must evaluate to true. In other words, the conditions are combined using `AND` operator. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the `Expected` map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

`Expected` contains the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, `a` is greater than `A`, and `a` is greater than `B`.

  For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- `ComparisonOperator` - A comparator for evaluating attributes in the `AttributeValueList`. When performing the comparison, DynamoDB uses strongly consistent reads.

  The following comparison operators are available:

  `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`

  The following are descriptions of each comparison operator.

  - `EQ` : Equal. `EQ` is supported for all data types, including lists and maps.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

  - `NE` : Not equal. `NE` is supported for all data types, including lists and maps.

    `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

  - `LE` : Less than or equal.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a

different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `LT` : Less than.

  `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `GE` : Greater than or equal.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `GT` : Greater than.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `NOT_NULL` : The attribute exists. `NOT_NULL` is supported for all data types, including lists and maps.

  > **Note**
  >
  > This operator tests for the existence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using `NOT_NULL`, the result is a Boolean `true`. This result is because the attribute "a" exists; its data type is not relevant to the `NOT_NULL` comparison operator.

- `NULL` : The attribute does not exist. `NULL` is supported for all data types, including lists and maps.

> **Note**
>
> This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using NULL, the result is a Boolean `false`. This is because the attribute "a" exists; its data type is not relevant to the NULL comparison operator.

- `CONTAINS` : Checks for a subsequence, or value in a set.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set.

  CONTAINS is supported for lists: When evaluating "a `CONTAINS` b", " a" can be a list; however, "b" cannot be a set, a map, or a list.

- `NOT_CONTAINS` : Checks for absence of a subsequence, or absence of a value in a set.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it `does not` find an exact match with any member of the set.

  NOT_CONTAINS is supported for lists: When evaluating "a `NOT CONTAINS` b", " a" can be a list; however, "b" cannot be a set, a map, or a list.

- `BEGINS_WITH` : Checks for a prefix.

  `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- `IN` : Checks for matching elements within two sets.

`AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- `BETWEEN` : Greater than or equal to the first value, and less than or equal to the second value.

  `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not compare to `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`

The following parameters can be used instead of `AttributeValueList` and `ComparisonOperator`:

- `Value` - A value for DynamoDB to compare with an attribute.
- `Exists` - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation:
  - If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluates to false.
  - If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

  Note that the default value for `Exists` is `true`.

The `Value` and `Exists` parameters are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

> **Note**
>
> This parameter does not support attributes of type List or Map.

Use *ConditionExpression* instead – Example

Suppose you wanted to modify an item in the *Music* table, but only if a certain condition was true. You could use an `UpdateItem` request with an `Expected` parameter, as in this AWS CLI example:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }' \
    --attribute-updates '{
        "Price": {
            "Action": "PUT",
            "Value": {"N":"1.98"}
        }
    }' \
    --expected '{
        "Price": {
            "ComparisonOperator": "LE",
            "AttributeValueList": [ {"N":"2.00"} ]
        }
    }'
```

You can use a `ConditionExpression` instead:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }' \
    --update-expression 'SET Price = :p1' \
    --condition-expression 'Price <= :p2' \
    --expression-attribute-values '{
        ":p1": {"N":"1.98"},
        ":p2": {"N":"2.00"}
```

```
    }'
```

KeyConditions (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *KeyConditionExpression* instead..

The legacy conditional parameter `KeyConditions` contains selection criteria for a `Query` operation. For a query on a table, you can have conditions only on the table primary key attributes. You must provide the partition key name and value as an `EQ` condition. You can optionally provide a second condition, referring to the sort key.

> **Note**
>
> If you don't provide a sort key condition, all of the items that match the partition key will be retrieved. If a `FilterExpression` or `QueryFilter` is present, it will be applied after the items are retrieved.

For a query on an index, you can have conditions only on the index key attributes. You must provide the index partition key name and value as an `EQ` condition. You can optionally provide a second condition, referring to the index sort key.

Each `KeyConditions` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- `ComparisonOperator` - A comparator for evaluating attributes. For example: equals, greater than, and less than.

  For `KeyConditions`, only the following comparison operators are supported:

  `EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN`

  The following are descriptions of these comparison operators.

  - `EQ` : Equal.

    `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

  - `LE` : Less than or equal.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

  - `LT` : Less than.

    `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

  - `GE` : Greater than or equal.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

  - `GT` : Greater than.

`AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `BEGINS_WITH` : Checks for a prefix.

  `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- `BETWEEN` : Greater than or equal to the first value, and less than or equal to the second value.

  `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not compare to `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

Use *KeyConditionExpression* instead – Example

Suppose you wanted to retrieve several items with the same partition key from the *Music* table. You could use a `Query` request with a `KeyConditions` parameter, as in this AWS CLI example:

```
aws dynamodb query \
    --table-name Music \
    --key-conditions '{
        "Artist":{
            "ComparisonOperator":"EQ",
            "AttributeValueList": [ {"S": "No One You Know"} ]
        },
        "SongTitle":{
            "ComparisonOperator":"BETWEEN",
            "AttributeValueList": [ {"S": "A"}, {"S": "M"} ]
        }
    }'
```

You can use a `KeyConditionExpression` instead:

```
aws dynamodb query \
    --table-name Music \
    --key-condition-expression 'Artist = :a AND SongTitle BETWEEN :t1 AND :t2' \
    --expression-attribute-values '{
        ":a": {"S": "No One You Know"},
        ":t1": {"S": "A"},
        ":t2": {"S": "M"}
    }'
```

QueryFilter (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *FilterExpression* instead..

In a `Query` operation, the legacy conditional parameter `QueryFilter` is a condition that evaluates the query results after the items are read and returns only the desired values.

This parameter does not support attributes of type List or Map.

> **Note**
>
> A `QueryFilter` is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

If you provide more than one condition in the `QueryFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are combined using the `AND` operator. (You can use the ConditionalOperator (legacy) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Note that `QueryFilter` does not allow key attributes. You cannot define a filter condition on a partition key or a sort key.

Each `QueryFilter` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator`.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

  For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

  For information on specifying data types in JSON, see DynamoDB low-level API.
- `ComparisonOperator` - A comparator for evaluating attributes. For example: equals, greater than, and less than.

  The following comparison operators are available:

  `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`

Use *FilterExpression* instead – Example

Suppose you wanted to query the *Music* table and apply a condition to the matching items. You could use a `Query` request with a `QueryFilter` parameter, as in this AWS CLI example:

```
aws dynamodb query \
    --table-name Music \
    --key-conditions '{
        "Artist": {
            "ComparisonOperator": "EQ",
            "AttributeValueList": [ {"S": "No One You Know"} ]
        }
    }' \
    --query-filter '{
        "Price": {
            "ComparisonOperator": "GT",
            "AttributeValueList": [ {"N": "1.00"} ]
        }
    }'
```

You can use a `FilterExpression` instead:

```
aws dynamodb query \
    --table-name Music \
    --key-condition-expression 'Artist = :a' \
    --filter-expression 'Price > :p' \
    --expression-attribute-values '{
        ":p": {"N":"1.00"},
        ":a": {"S":"No One You Know"}
    }'
```

ScanFilter (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *FilterExpression* instead..

In a `Scan` operation, the legacy conditional parameter `ScanFilter` is a condition that evaluates the scan results and returns only the desired values.

> **Note**
>
> This parameter does not support attributes of type List or Map.

If you specify more than one condition in the `ScanFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the ConditionalOperator (legacy) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Each `ScanFilter` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator` .

  For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

For information on specifying data types in JSON, see DynamoDB low-level API.

- `ComparisonOperator` - A comparator for evaluating attributes. For example: equals, greater than, and less than.

  The following comparison operators are available:

  `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`

Use *FilterExpression* instead – Example

Suppose you wanted to scan the *Music* table and apply a condition to the matching items. You could use a `Scan` request with a `ScanFilter` parameter, as in this AWS CLI example:

```
aws dynamodb scan \
    --table-name Music \
    --scan-filter '{
        "Genre":{
            "AttributeValueList":[ {"S":"Rock"} ],
            "ComparisonOperator": "EQ"
        }
    }'
```

You can use a `FilterExpression` instead:

```
aws dynamodb scan \
    --table-name Music \
    --filter-expression 'Genre = :g' \
    --expression-attribute-values '{
        ":g": {"S":"Rock"}
    }'
```

Writing conditions with legacy parameters

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB.

The following section describes how to write conditions for use with legacy parameters, such as `Expected`, `QueryFilter`, and `ScanFilter`.

> **Note**
>
> New applications should use expression parameters instead. For more information, see Using expressions in DynamoDB.

Simple conditions

With attribute values, you can write conditions for comparisons against table attributes. A condition always evaluates to true or false, and consists of:

- `ComparisonOperator` — greater than, less than, equal to, and so on.
- `AttributeValueList` (optional) — attribute value(s) to compare against. Depending on the `ComparisonOperator` being used, the `AttributeValueList` might contain one, two, or more values; or it might not be present at all.

The following sections describe the various comparison operators, along with examples of how to use them in conditions.

Comparison operators with no attribute values

- `NOT_NULL` - true if an attribute exists.
- `NULL` - true if an attribute does not exist.

Use these operators to check whether an attribute exists, or doesn't exist. Because there is no value to compare against, do not specify `AttributeValueList`.

Example

The following expression evaluates to true if the *Dimensions* attribute exists.

```
...
    "Dimensions": {
         ComparisonOperator: "NOT_NULL"
    }
...
```

Comparison operators with one attribute value

- `EQ` - true if an attribute is equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match. For example, the string `"3"` is not equal to the number `3`. Also, the number `3` is not equal to the number set `[3, 2, 1]`.
- `NE` - true if an attribute is not equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match.
- `LE` - true if an attribute is less than or equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match.
- `LT` - true if an attribute is less than a value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.
- `GE` - true if an attribute is greater than or equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.
- `GT` - true if an attribute is greater than a value.

`AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- `CONTAINS` - true if a value is present within a set, or if one value contains another.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for a substring match. If the target attribute of the comparison is Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it finds an exact match with any member of the set.

- `NOT_CONTAINS` - true if a value is *not* present within a set, or if one value does not contain another value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it *does not* find an exact match with any member of the set.

- `BEGINS_WITH` - true if the first few characters of an attribute match the provided value. Do not use this operator for comparing numbers.

  `AttributeValueList` can contain only one value of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).

Use these operators to compare an attribute with a value. You must specify an `AttributeValueList` consisting of a single value. For most of the operators, this value must be a scalar; however, the `EQ` and `NE` operators also support sets.

Examples

The following expressions evaluate to true if:

- A product's price is greater than 100.

```
...
    "Price": {
```

```
        ComparisonOperator: "GT",
        AttributeValueList: [ {"N":"100"} ]
    }
...
```

- A product category begins with "Bo".

```
...
    "ProductCategory": {
        ComparisonOperator: "BEGINS_WITH",
        AttributeValueList: [ {"S":"Bo"} ]
    }
...
```

- A product is available in either red, green, or black:

```
...
    "Color": {
        ComparisonOperator: "EQ",
        AttributeValueList: [
            [ {"S":"Black"}, {"S":"Red"}, {"S":"Green"} ]
        ]
    }
...
```

> **Note**
>
> When comparing set data types, the order of the elements does not matter. DynamoDB will return only the items with the same set of values, regardless of the order in which you specify them in your request.

Comparison operators with two attribute values

- `BETWEEN` - true if a value is between a lower bound and an upper bound, endpoints inclusive.

  `AttributeValueList` must contain two elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains a value of a different type than the one specified in the request, the value does not match.

Use this operator to determine if an attribute value is within a range. The `AttributeValueList` must contain two scalar elements of the same type - String, Number, or Binary.

Example

The following expression evaluates to true if a product's price is between 100 and 200.

```
...
    "Price": {
        ComparisonOperator: "BETWEEN",
        AttributeValueList: [ {"N":"100"}, {"N":"200"} ]
    }
...
```

Comparison operators with *n* attribute values

- `IN` - true if a value is equal to any of the values in an enumerated list. Only scalar values are supported in the list, not sets. The target attribute must be of the same type and exact value in order to match.

  `AttributeValueList` can contain one or more elements of type String, Number, or Binary (not a set). These attributes are compared against an existing non-set type attribute of an item. If *any* elements of the input set are present in the item attribute, the expression evaluates to true.

  `AttributeValueList` can contain one or more values of type String, Number, or Binary (not a set). The target attribute of the comparison must be of the same type and exact value to match. A String never matches a String set.

Use this operator to determine whether the supplied value is within an enumerated list. You can specify any number of scalar values in `AttributeValueList`, but they all must be of the same data type.

Example

The following expression evaluates to true if the value for *Id* is 201, 203, or 205.

```
...
    "Id": {
        ComparisonOperator: "IN",
        AttributeValueList: [ {"N":"201"}, {"N":"203"}, {"N":"205"} ]
```

```
    }
...
```

Using multiple conditions

DynamoDB lets you combine multiple conditions to form complex expressions. You do this by providing at least two expressions, with an optional ConditionalOperator (legacy).

By default, when you specify more than one condition, *all* of the conditions must evaluate to true in order for the entire expression to evaluate to true. In other words, an implicit *AND* operation takes place.

Example

The following expression evaluates to true if a product is a book that has at least 600 pages. Both of the conditions must evaluate to true, since they are implicitly *AND*ed together.

```
...
    "ProductCategory": {
        ComparisonOperator: "EQ",
        AttributeValueList: [ {"S":"Book"} ]
    },
    "PageCount": {
        ComparisonOperator: "GE",
        AttributeValueList: [ {"N":600} ]
    }
...
```

You can use ConditionalOperator (legacy) to clarify that an *AND* operation will take place. The following example behaves in the same manner as the previous one.

```
...
    "ConditionalOperator" : "AND",
    "ProductCategory": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"N":"Book"} ]
    },
    "PageCount": {
        "ComparisonOperator": "GE",
        "AttributeValueList": [ {"N":600} ]
    }
```

```
...
```

You can also set `ConditionalOperator` to *OR*, which means that *at least one* of the conditions must evaluate to true.

Example

The following expression evaluates to true if a product is a mountain bike, if it is a particular brand name, or if its price is greater than 100.

```
...
    ConditionalOperator : "OR",
    "BicycleType": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"S":"Mountain" ]
    },
    "Brand": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"S":"Brand-Company A" ]
    },
    "Price": {
        "ComparisonOperator": "GT",
        "AttributeValueList": [ {"N":"100"} ]
    }
...
```

Note

In a complex expression, the conditions are processed in order, from the first condition to the last.
You cannot use both AND and OR in a single expression.

Other conditional operators

In previous releases of DynamoDB, the `Expected` parameter behaved differently for conditional writes. Each item in the `Expected` map represented an attribute name for DynamoDB to check, along with the following:

- `Value` — a value to compare against the attribute.
- `Exists` — determine whether the value exists prior to attempting the operation.

The `Value` and `Exists` options continue to be supported in DynamoDB; however, they only let you test for an equality condition, or whether an attribute exists. We recommend that you use `ComparisonOperator` and `AttributeValueList` instead, because these options let you construct a much wider range of conditions.

Example

A `DeleteItem` can check to see whether a book is no longer in publication, and only delete it if this condition is true. Here is an AWS CLI example using a legacy condition:

```
aws dynamodb delete-item \
    --table-name ProductCatalog \
    --key '{
        "Id": {"N":"600"}
    }' \
    --expected '{
        "InPublication": {
            "Exists": true,
            "Value": {"BOOL":false}
        }
    }'
```

The following example does the same thing, but does not use a legacy condition:

```
aws dynamodb delete-item \
    --table-name ProductCatalog \
    --key '{
        "Id": {"N":"600"}
    }' \
    --expected '{
        "InPublication": {
            "ComparisonOperator": "EQ",
            "AttributeValueList": [ {"BOOL":false} ]
        }
    }'
```

Example

A `PutItem` operation can protect against overwriting an existing item with the same primary key attributes. Here is an example using a legacy condition:

```
aws dynamodb put-item \
    --table-name ProductCatalog \
    --item '{
      "Id": {"N":"500"},
        "Title": {"S":"Book 500 Title"}
    }' \
    --expected '{
        "Id": { "Exists": false }
    }'
```

The following example does the same thing, but does not use a legacy condition:

```
aws dynamodb put-item \
    --table-name ProductCatalog \
    --item '{
      "Id": {"N":"500"},
        "Title": {"S":"Book 500 Title"}
    }' \
    --expected '{
        "Id": { "ComparisonOperator": "NULL" }
    }'
```

Note

For conditions in the `Expected` map, do not use the legacy `Value` and `Exists` options together with `ComparisonOperator` and `AttributeValueList`. If you do this, your conditional write will fail.
