For example, suppose that you issue a `GetItem` request from the DAX client to read an item from the `ProductCatalog` table. (The partition key is `Id`, and there is no sort key.) You retrieve the item whose `Id` is `101`. The `QuantityOnHand` value for that item is `42`. DAX stores the item in its item cache with a specific TTL. For this example, assume that the TTL is 10 minutes. Then, 3 minutes later, another application uses the DAX client to update the same item so that its `QuantityOnHand` value is now `41`. Assuming that the item is not updated again, any subsequent reads of the same item during the next 10 minutes return the cached value for `QuantityOnHand` (`41`).

How DAX processes writes

DAX is intended for applications that require high-performance reads. As a write-through cache, DAX passes your writes through to DynamoDB synchronously, then automatically and asynchronously replicates resulting updates to your item cache across all nodes in the cluster. You don't need to manage cache invalidation logic because DAX handles it for you.

DAX supports the following write operations: `PutItem`, `UpdateItem`, `DeleteItem`, `BatchWriteItem`, and `TransactWriteItems`.

When you send a `PutItem`, `UpdateItem`, `DeleteItem`, or `BatchWriteItem` request to DAX, the following occurs:

- DAX sends the request to DynamoDB.
- DynamoDB replies to DAX, confirming that the write succeeded.
- DAX writes the item to its item cache.
- DAX returns success to the requester.

When you send a `TransactWriteItems` request to DAX, the following occurs:

- DAX sends the request to DynamoDB.
- DynamoDB replies to DAX, confirming that the transaction completed.
- DAX returns success to the requester.
- In the background, DAX makes a `TransactGetItems` request for each item in the `TransactWriteItems` request to store the item in the item cache. `TransactGetItems` is used to ensure serializable isolation.

If a write to DynamoDB fails for any reason, including throttling, the item is not cached in DAX. The exception for the failure is returned to the requester. This ensures that data is not written to the DAX cache unless it is first written successfully to DynamoDB.

> **Note**
>
> Every write to DAX alters the state of the item cache. However, writes to the item cache don't affect the query cache. (The DAX item cache and query cache serve different purposes, and operate independently from one another.)

DAX query cache behavior

DAX caches the results from `Query` and `Scan` requests in its query cache. However, these results don't affect the item cache at all. When your application issues a `Query` or `Scan` request with DAX, the result set is saved in the query cache—not in the item cache. You can't "warm up" the item cache by performing a `Scan` operation because the item cache and query cache are separate entities.

Consistency of query-update-query

Updates to the item cache, or to the underlying DynamoDB table, do not invalidate or modify the results stored in the query cache.

To illustrate, consider the following scenario. An application is working with the `DocumentRevisions` table, which has `DocId` as its partition key and `RevisionNumber` as its sort key.

1. A client issues a `Query` for `DocId` `101`, for all items with `RevisionNumber` greater than or equal to 5. DAX stores the result set in the query cache and returns the result set to the user.
2. The client issues a `PutItem` request for `DocId` `101` with a `RevisionNumber` value of `20`.
3. The client issues the same `Query` as described in step 1 (`DocId` `101` and `RevisionNumber` >= 5).

In this scenario, the cached result set for the `Query` issued in step 3 is identical to the result set that was cached in step 1. The reason is that DAX does not invalidate `Query` or `Scan` result sets based on updates to individual items. The `PutItem` operation from step 2 is only reflected in the DAX query cache when the TTL for the `Query` expires.

Your application should consider the TTL value for the query cache and how long your application can tolerate inconsistent results between the query cache and the item cache.

Strongly consistent and transactional reads

To perform a strongly consistent `GetItem`, `BatchGetItem`, `Query`, or `Scan` request, you set the `ConsistentRead` parameter to true. DAX passes strongly consistent read requests to DynamoDB. When it receives a response from DynamoDB, DAX returns the results to the client, but it does not cache the results. DAX can't serve strongly consistent reads by itself because it's not

tightly coupled to DynamoDB. For this reason, any subsequent reads from DAX would have to be eventually consistent reads. And any subsequent strongly consistent reads would have to be passed through to DynamoDB.

DAX handles `TransactGetItems` requests the same way it handles strongly consistent reads. DAX passes all `TransactGetItems` requests to DynamoDB. When it receives a response from DynamoDB, DAX returns the results to the client, but it doesn't cache the results.

Negative caching

DAX supports negative cache entries in both the item cache and the query cache. A *negative cache entry* occurs when DAX can't find requested items in an underlying DynamoDB table. Instead of generating an error, DAX caches an empty result and returns that result to the user.

For example, suppose that an application sends a `GetItem` request to a DAX cluster, and that there is no matching item in the DAX item cache. This causes DAX to read the corresponding item from the underlying DynamoDB table. If the item doesn't exist in DynamoDB, DAX stores an empty item in its item cache and returns the empty item to the application. Now suppose that the application sends another `GetItem` request for the same item. DAX finds the empty item in the item cache and returns it to the application immediately. It does not consult DynamoDB at all.

A negative cache entry remains in the DAX item cache until its item TTL has expired, its LRU is invoked, or the item is modified using `PutItem`, `UpdateItem`, or `DeleteItem`.

The DAX query cache handles negative cache results in a similar way. If an application performs a `Query` or `Scan`, and the DAX query cache doesn't contain a cached result, DAX sends the request to DynamoDB. If there are no matching items in the result set, DAX stores an empty result set in the query cache and returns the empty result set to the application. Subsequent `Query` or `Scan` requests yield the same (empty) result set, until the TTL for that result set has expired.

Strategies for writes

The write-through behavior of DAX is appropriate for many application patterns. However, there are some application patterns where a write-through model might not be appropriate.

For applications that are sensitive to latency, writing through DAX incurs an extra network hop. So a write to DAX is a little slower than a write directly to DynamoDB. If your application is sensitive to write latency, you can reduce the latency by writing directly to DynamoDB instead. For more information, see Write-around.

For write-intensive applications (such as those that perform bulk data loading), you might not want to write all of the data through DAX because only a small percentage of that data is ever read by the application. When you write large amounts of data through DAX, it must invoke its LRU algorithm to make room in the cache for the new items to be read. This diminishes the effectiveness of DAX as a read cache.

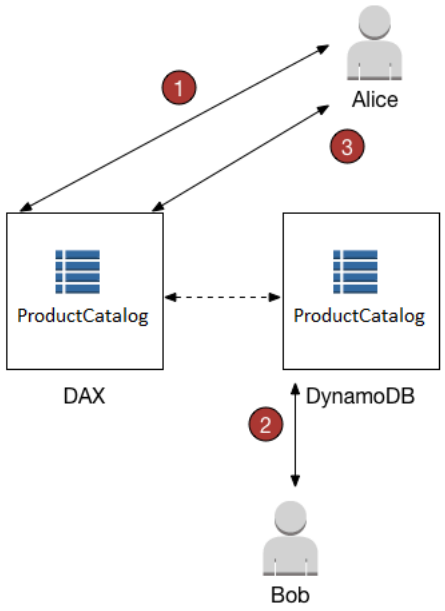
When you write an item to DAX, the item cache state is altered to accommodate the new item. (For example, DAX might need to evict older data from the item cache to make room for the new item.) The new item remains in the item cache, subject to the cache's LRU algorithm and the TTL setting for the cache. As long as the item persists in the item cache, DAX doesn't re-read the item from DynamoDB.

Write-through

The DAX item cache implements a write-through policy. For more information, see How DAX processes writes.

When you write an item, DAX ensures that the cached item is synchronized with the item as it exists in DynamoDB. This is helpful for applications that need to re-read an item immediately after writing it. However, if other applications write directly to a DynamoDB table, the item in the DAX item cache is no longer in sync with DynamoDB.

To illustrate, consider two users (Alice and Bob), who are working with the `ProductCatalog` table. Alice accesses the table using DAX, but Bob bypasses DAX and accesses the table directly in DynamoDB.



1. Alice updates an item in the `ProductCatalog` table. DAX forwards the request to DynamoDB, and the update succeeds. DAX then writes the item to its item cache and returns a successful response to Alice. From that point on, until the item is ultimately evicted from the cache, any user who reads the item from DAX sees the item with Alice's update.
2. A short time later, Bob updates the same `ProductCatalog` item that Alice wrote. However, Bob updates the item directly in DynamoDB. DAX does not automatically refresh its item cache in response to updates through DynamoDB. Therefore, DAX users don't see Bob's update.
3. Alice reads the item from DAX again. The item is in the item cache, so DAX returns it to Alice without accessing the DynamoDB table.

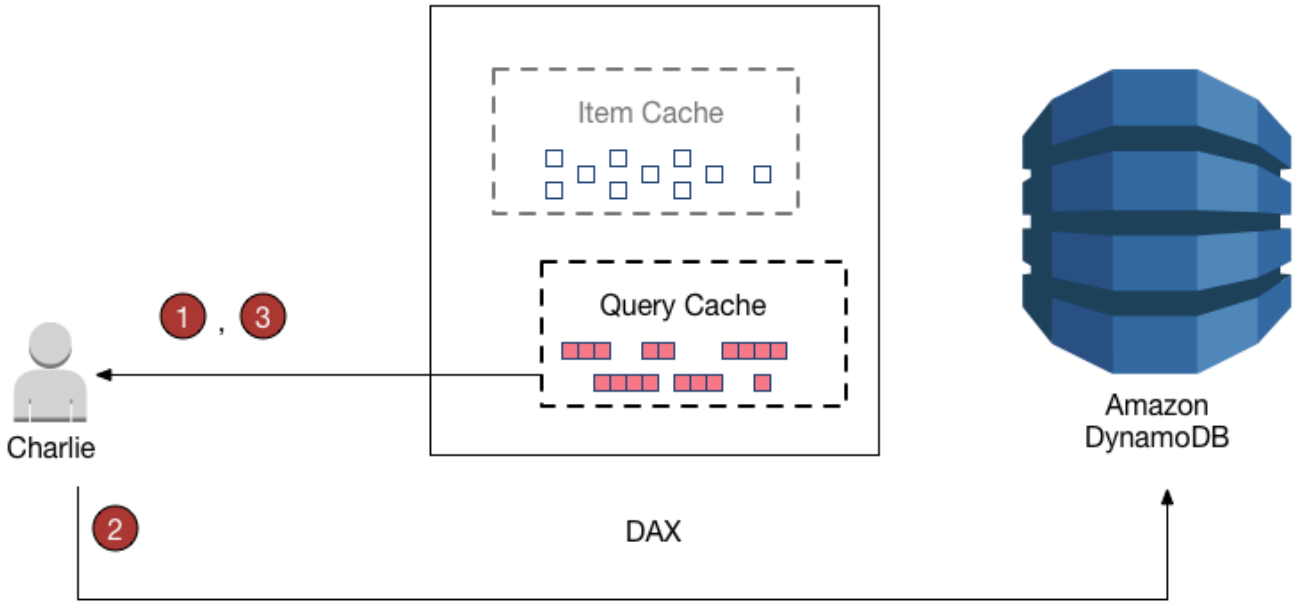
In this scenario, Alice and Bob see different representations of the same `ProductCatalog` item. This is the case until DAX evicts the item from the item cache, or until another user updates the same item again using DAX.

Write-around

If your application needs to write large quantities of data (such as a bulk data load), it might make sense to bypass DAX and write the data directly to DynamoDB. Such a *write-around* strategy reduces write latency. However, the item cache doesn't remain in sync with the data in DynamoDB.

If you decide to use a write-around strategy, remember that DAX populates its item cache whenever applications use the DAX client to read data. This can be advantageous in some cases because it ensures that only the most frequently read data is cached (as opposed to the most frequently written data).

For example, consider a user (Charlie) who wants to work with a different table, the `GameScores` table, using DAX. The partition key for `GameScores` is `UserId`, so all of Charlie's scores would have the same `UserId`.



1. Charlie wants to retrieve all of his scores, so he sends a `Query` to DAX. Assuming that this query has not been issued before, DAX forwards the query to DynamoDB for processing. It stores the results in the DAX query cache, and then returns the results to Charlie. The result set remains available in the query cache until it is evicted.
2. Now suppose that Charlie plays the Meteor Blasters game and achieves a high score. Charlie sends an `UpdateItem` request to DynamoDB, modifying an item in the `GameScores` table.
3. Finally, Charlie decides to rerun his earlier `Query` to retrieve all of his data from `GameScores`. Charlie does not see his high score for Meteor Blasters in the results. This is because the query results come from the query cache, not the item cache. The two caches are independent from one another, so a change in one cache does not affect the other cache.

DAX does not refresh result sets in the query cache with the most current data from DynamoDB. Each result set in the query cache is current as of the time that the `Query` or `Scan` operation was performed. Thus, Charlie's `Query` results don't reflect his `PutItem` operation. This is the case until DAX evicts the result set from the query cache.

Developing with the DynamoDB Accelerator (DAX) client

To use DAX from an application, you use the DAX client for your programming language. The DAX client is designed for minimal disruption to your existing Amazon DynamoDB applications—with only a few simple code modifications needed.

> **Note**
>
> DAX clients for various programming languages are available on the following site:
>
> - http://dax-sdk.s3-website-us-west-2.amazonaws.com

This section demonstrates how to launch an Amazon EC2 instance in your default Amazon VPC, connect to the instance, and run a sample application. It also provides information about how to modify your existing application so that it can use your DAX cluster.

Topics

- Tutorial: Running a sample application using DynamoDB Accelerator (DAX)
- Modifying an existing application to use DAX

Tutorial: Running a sample application using DynamoDB Accelerator (DAX)

This tutorial demonstrates how to launch an Amazon EC2 instance in your default virtual private cloud (VPC), connect to the instance, and run a sample application that uses Amazon DynamoDB Accelerator (DAX).

> **Note**
>
> To complete this tutorial, you must have a DAX cluster running in your default VPC. If you haven't created a DAX cluster, see Creating a DAX cluster for instructions.

Topics

- Step 1: Launch an Amazon EC2 instance
- Step 2: Create a user and policy
- Step 3: Configure an Amazon EC2 instance
- Step 4: Run a sample application

Step 1: Launch an Amazon EC2 instance

When your Amazon DynamoDB Accelerator (DAX) cluster is available, you can launch an Amazon EC2 instance in your default Amazon Virtual Private Cloud (Amazon VPC). You can then install and run DAX client software on that instance.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance**, and do the following:

   Step 1: Choose an Amazon Machine Image (AMI)

   1. In the list of AMIs, find the **Amazon Linux AMI**, and choose **Select**.

   Step 2: Choose an Instance Type

   1. In the list of instance types, choose **t2.micro**.
   2. Choose **Next: Configure Instance Details**.

   Step 3: Configure Instance Details

   1. For **Network**, choose your default VPC.
   2. Choose **Next: Add Storage**.

   Step 4: Add Storage

   1. Skip this step by choosing **Next: Add Tags**.

Step 5: Add Tags

1. Skip this step by choosing **Next: Configure Security Group**.

Step 6: Configure Security Group

1. Choose **Select an existing security group**.
2. In the list of security groups, choose **default**. This is the default security group for your VPC.
3. Choose **Next: Review and Launch**.

Step 7: Review Instance Launch

1. Choose **Launch**.

3. In the **Select an existing key pair or create a new key pair** window, do one of the following:

   - If you don't have an Amazon EC2 key pair, choose **Create a new key pair** and follow the instructions. You are asked to download a private key file (`.pem` file). You need this file later when you log in to your Amazon EC2 instance.
   - If you already have an existing Amazon EC2 key pair, go to **Select a key pair** and choose your key pair from the list. You must already have the private key file (`.pem` file) available in order to log in to your Amazon EC2 instance.

4. After configuring your key pair, choose **Launch Instances**.
5. In the console navigation pane, choose **EC2 Dashboard**, and then choose the instance that you launched. In the lower pane, on the **Description** tab, find the **Public DNS** for your instance, for example: `ec2-11-22-33-44.us-west-2.compute.amazonaws.com`. Make a note of this public DNS name because you need it for Step 3: Configure an Amazon EC2 instance.

> **Note**
>
> It takes a few minutes for your Amazon EC2 instance to become available. In the meantime, proceed to Step 2: Create a user and policy and follow the instructions there.

Step 2: Create a user and policy

In this step, you create a user with a policy that grants access to your Amazon DynamoDB Accelerator (DAX) cluster and to DynamoDB using AWS Identity and Access Management. You can then run applications that interact with your DAX cluster.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose **Policies**.

   If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.
3. At the top of the page, choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Enter or paste a JSON policy document. For details about the IAM policy language, see IAM JSON policy reference.
6. Resolve any security warnings, errors, or general warnings generated during policy validation, and then choose **Next**.

> **Note**
>
> You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see Policy restructuring in the *IAM User Guide*.

7. (Optional) When you create or edit a policy in the AWS Management Console, you can generate a JSON or YAML policy template that you can use in CloudFormation templates.

   To do this, in the **Policy editor** choose **Actions**, and then choose **Generate CloudFormation template**. To learn more about CloudFormation, see AWS Identity and Access Management resource type reference in the *AWS CloudFormation User Guide*.
8. When you are finished adding permissions to the policy, choose **Next**.
9. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
10. (Optional) Add metadata to the policy by attaching tags as key-value pairs. For more information about using tags in IAM, see Tags for AWS Identity and Access Management resources in the *IAM User Guide*.
11. Choose **Create policy** to save your new policy.

Policy document – Copy and paste the following document to create the JSON policy.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "dax:*"
            ],
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
```

```
        },
        {
            "Action": [
                "dynamodb:*"
            ],
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
        }
    ]
}
```

Step 3: Configure an Amazon EC2 instance

When your Amazon EC2 instance is available, you can log in to the instance and prepare it for use.

> **Note**
>
> The following steps assume that you are connecting to your Amazon EC2 instance from a computer running Linux. For other ways to connect, see Connect to Your Linux Instance in the *Amazon EC2 User Guide*.

To configure the EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Use the `ssh` command to log in to your Amazon EC2 instance, as shown in the following example.

   ```
   ssh -i my-keypair.pem ec2-user@public-dns-name
   ```

   You need to specify your private key file (`.pem` file) and the public DNS name of your instance. (See Step 1: Launch an Amazon EC2 instance.)

   The login ID is `ec2-user`. No password is required.
3. After you log in to your EC2 instance, configure your AWS credentials as shown following. Enter your AWS access key ID and secret key (from Step 2: Create a user and policy), and set

the default Region name to your current Region. (In the following example, the default Region name is `us-west-2`.)

```
aws configure

AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]:
```

After launching and configuring your Amazon EC2 instance, you can test the functionality of DAX using one of the available sample applications. For more information, see Step 4: Run a sample application.

Step 4: Run a sample application

To help you test Amazon DynamoDB Accelerator (DAX) functionality, you can run one of the available sample applications on your Amazon EC2 instance.

- .NET and DAX
- Python and DAX

Node.js and DAX

Default client configuration for Node.js

When configuring the DAX JavaScript SDK client, you can customize various parameters to optimize performance, connection handling, and error resilience. The following table outlines the default configuration settings that control how your client interacts with the DAX cluster, including timeout values, retry mechanisms, credential management, and health monitoring options. For more information, see DynamoDBClient Operations.

DAX JS SDK client defaults

Parameter	Type	Description
`region` optional	`string`	The AWS Region to use for the DAX client (example - 'us-east-1'). This is a required parameter if not provided through the environment variable.
`endpoint` required	`string`	The endpoint of the Cluster to which the SDK connects. Examples: Non-encrypted – dax-cluster-name.region.amazonaws.com Encrypted – daxs://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
`requestTimeout` default 6000 ms	`number`	This defines the maximum time the client will wait for a response from DAX.
`writeRetries` default 1	`number`	The number of retries to attempt for write requests that fail.
`readRetries` default 1	`number`	The number of retries to attempt for read requests that fail.
`maxRetries` default 1	`number`	The maximum number of retries to attempt on failed requests.

Parameter	Type	Description
		If readRetries/writeRetries are set, then the configuration set in readRetries and writeRetries take priority over maxRetries.
`connectTimeout` default 10000 ms	`number`	The timeout (in milliseconds) for establishing a connection to any of the cluster nodes.
`maxConcurrentConnections` default 100	`number`	Limits the total number of concurrent connections that a client instance can create per node in a DAX cluster.

Parameter	Type	Description
`maxRetryDelay` default 7000 ms	`number`	When the DAX server indicates recover is needed by setting `waitForRecoveryBeforeRetrying` flag to true, the client will pause before retry attempts. During these recovery periods, the `maxRetryDelay` parameter determines the maximum waiting time between retries. This recovery-specific configuration only applies when the DAX server is in recovery mode. For all other scenarios, retry behavior follows one of two patterns: either an exponential delay based on the retry count (governed by `writeRetries`, `readRetries`, or `maxRetries` parameters), or an immediate retry depending on the exception type.

Parameter	Type	Description
`credentials` optional	AwsCredentialIdentity | AwsCredentialIdentityProvider	The AWS credentials to use for authenticating requests. This can be provided as an AwsCredentialIdentity or an AwsCredentialIdentityProvider. If not provided, the AWS SDK will automatically use the default credentials provider chain. Example: `{ accessKeyId: 'AKIA...', secretAccessKey: '...', sessionToken: '...' }` * @default Uses default AWS credentials provider chain.
`healthCheckInterval` default 5000 ms	`number`	The interval (in milliseconds) between cluster health checks. A lower interval will check more frequently.
`healthCheckTimeout` default 1000 ms	`number`	The timeout (in milliseconds) for the health check to complete.

Parameter	Type	Description
`skipHostnameVerification` default false	`boolean`	Skip hostname verification of TLS connections. This has no impact on un-encrypted clusters. The default is to perform hostname verification, setting this to True will skip verification. Be sure you understand the implication of turning it off, which is the inability to authenticate the cluster that you are connecting to.
`unhealthyConsecutiveErrorCount` default 5	`number`	Sets the number of consecutive errors required to signal node unhealthy within health check interval.
`clusterUpdateInterval` default 4000 ms	`number`	Returns the interval between polling of cluster members for membership changes.
`clusterUpdateThreshold` default 125	`number`	Returns the threshold below which the cluster will not be polled for membership changes.
`credentailProvider` optional | default null	AwsCredentialIdentityProvider	User Defined Provider for AWS credentials used to authenticate requests to DAX.

Pagination configuration for DaxDocument

Name	Type	Detail
`client`	DaxDocument	Instance of DaxDocument type.
`pageSize`	number	Determines the number of items per page.
`startingToken` Optional	any	LastEvaluatedKey from previous response can be used for subsequent requests.

For usage of pagination, see the section called “TryDax.js”.

Migrating to DAX Node.js SDK V3

This migration guide will help you transition your existing DAX Node.js applications. The new SDK requires Node.js 18 or higher and introduces several important changes in how you'll structure your DynamoDB Accelerator code. This guide will walk you through the key differences, including syntax changes, new import methods, and updated asynchronous programming patterns.

V2 Node.js DAX usage

```
const AmazonDaxClient = require('amazon-dax-client');
const AWS = require('aws-sdk');

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var client = new AWS.DynamoDB.DocumentClient();

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
```

```
  client = new AWS.DynamoDB.DocumentClient({ service: dax });
}

// Make Get Call using Dax
var params = {
    TableName: 'TryDaxTable',
    pk: 1,
    sk: 1
}
client.get(params, function (err, data) {
    if (err) {
        console.error(
            "Unable to read item. Error JSON:",
            JSON.stringify(err, null, 2)
          );
    } else {
        console.log(data);
    }
});
```

V3 Node.js DAX usage

For Using DAX Node.js V3 Node version 18 or above is the preferred version. To move to Node 18, use the following:

```
import { DaxDocument } from '@amazon-dax-sdk/lib-dax';
import { DynamoDBDocument } from '@aws-sdk/lib-dynamodb';
import { DynamoDBClient } from '@aws-sdk/client-dynamodb';

let client: DynamoDBDocument | DaxDocument = DynamoDBDocument.from(
  new DynamoDBClient({ region: 'us-west-2' })
);

if (process.argv.length > 2) {
  client = new DaxDocument({
    endpoints: [process.argv[2]],
    region: 'us-west-2',
  });
}

const params = {
  TableName: 'TryDaxTable',
  Key: { pk: 1, sk: 1 },
```

```
};

try {
  const results = await client.get(params);
  console.log(results);
} catch (err) {
  console.error(err);
}
```

The DAX SDK for Node.js v3.x is compatible with AWS SDK for Node.js v3.x. The DAX SDK for Node.js v3.x supports the use of aggregated clients. Note that DAX doesn't support the creation of bare-bones clients. For more information about unsupported features, see the section called "Features not in parity with AWS SDK V3".

Follow these steps to run the Node.js sample application on your Amazon EC2 instance.

To run the Node.js sample for DAX

1. Set up Node.js on your Amazon EC2 instance, as follows:

   a. Install node version manager (nvm).

   ```
   curl -o- https://raw.githubusercontent.com/nvm-sh/nvm/v0.40.1/install.sh | bash
   ```

   b. Use nvm to install Node.js.

   ```
   nvm install 18
   ```

   c. Use nvm to use Node 18

   ```
   nvm use 18
   ```

   d. Test that Node.js is installed and running correctly.

   ```
   node -e "console.log('Running Node.js ' + process.version)"
   ```

   This should display the following message.

   ```
   Running Node.js v18.x.x
   ```

2. Install the DaxDocument Node.js client using the node package manager (npm).

```
npm install @amazon-dax-sdk/lib-dax
```

TryDax sample code

To evaluate the performance benefits of DynamoDB Accelerator (DAX), follow these steps to run a sample test that compares read operation times between standard DynamoDB and a DAX cluster.

1. After you've set up your workspace and installed the `lib-dax` as a dependency, copy the section called “TryDax.js” into your project.
2. Run the program against your DAX cluster. To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

     ```
     dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
     ```

   - **Using the AWS CLI** — Enter the following command.

     ```
     aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
     ```

     The cluster endpoint is shown in the output, as in the following example.

     ```
     {
         "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
         "Port": 8111,
         "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
     }
     ```

3. Now run the program by specifying the cluster endpoint as a command line parameter.

   ```
   node TryDax.js dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
   ```

   You should see output similar to the following:

   ```
   Attempting to create table; please wait...
   Successfully created table. Table status: ACTIVE
   ```

```
Writing data to the table...
Writing 20 items for partition key:  1

  { pk: 1, sk: 6, someData: 'XXXXXXXXXX' }
]
...
Attempting to delete table; please wait...
Successfully deleted table.
```

Take note of the timing information. The number of microseconds required for the `GetItem`,`Query`,`Scan` tests.

4. In this case, you ran the programs against the DAX cluster. Now, you'll run the program again, this time against DynamoDB.
5. Now run the program again, but this time, without the cluster endpoint URL as a command line parameter.

```
node TryDax.js
```

Look at the output and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX as compared to DynamoDB.

Features not in parity with AWS SDK V3

- Bare-bones clients – Dax Node.js V3 doesn't support bare-bones clients.

```
const dynamoDBClient = new DynamoDBClient({ region: 'us-west-2' });
const regularParams = {
    TableName: 'TryDaxTable',
    Key: {
        pk: 1,
        sk: 1
    }
};
// The DynamoDB client supports the send operation.
const dynamoResult = await dynamoDBClient.send(new GetCommand(regularParams));

// However, the DaxDocument client does not support the send operation.
const daxClient = new DaxDocument({
    endpoints: ['your-dax-endpoint'],
    region: 'us-west-2',
});
```

```
const params = {
    TableName: 'TryDaxTable',
    Key: {
        pk: 1,
        sk: 1
    }
};

// This will throw an error - send operation is not supported for DAX. Please refer
 to documentation.
const result = await daxClient.send(new GetCommand(params));
console.log(result);
```

- Middleware Stack – Dax Node.js V3 doesn't support using Middleware functions.

```
const dynamoDBClient = new DynamoDBClient({ region: 'us-west-2' });
// The DynamoDB client supports the middlewareStack.
dynamoDBClient.middlewareStack.add(
  (next, context) =>> async (args) => {
    console.log("Before operation:", args);
    const result = await next(args);
    console.log("After operation:", result);
    return result;
  },
  {
    step: "initialize", // or "build", "finalizeRequest", "deserialize"
    name: "loggingMiddleware",
  }
);

// However, the DaxDocument client does not support the middlewareStack.
const daxClient = new DaxDocument({
    endpoints: ['your-dax-endpoint'],
    region: 'us-west-2',
});

// This will throw an error - custom middleware and middlewareStacks are not
 supported for DAX. Please refer to documentation.
daxClient.middlewareStack.add(
  (next, context) => async (args) => {
    console.log("Before operation:", args);
    const result = await next(args);
```

```
    console.log("After operation:", result);
    return result;
  },
  {
    step: "initialize", // or "build", "finalizeRequest", "deserialize"
    name: "loggingMiddleware",
  }
);
```

TryDax.js

```
import { DynamoDB, waitUntilTableExists, waitUntilTableNotExists } from "@aws-sdk/
client-dynamodb";
import { DaxDocument, daxPaginateScan, daxPaginateQuery } from "@amazon-dax-sdk/lib-
dax";
import { DynamoDBDocument, paginateQuery, paginateScan } from "@aws-sdk/lib-dynamodb";

const region = "us-east-1";

}

// Execute functions sequentially
```

```
(async function () {
  await createTable();
  await writeData();
  await getItemTest();
  await queryTest();
  await scanTest();
  await paginationTest();
  await deleteTable();
})();
```

DAX SDK for Go

Follow this procedure to run the Amazon DynamoDB Accelerator (DAX) SDK for Go sample application on your Amazon EC2 instance.

To run the SDK for Go sample for DAX

1. Set up the SDK for Go on your Amazon EC2 instance:

   a. Install the Go programming language (`Golang`).

   ```
   sudo yum install -y golang
   ```

   b. Test that Golang is installed and running correctly.

   ```
   go version
   ```

   A message like this should appear.

   ```
   go version go1.23.4 linux/amd64
   ```

2. Install the sample Golang application.

   ```
   go get github.com/aws-samples/sample-aws-dax-go-v2
   ```

3. Run the following Golang programs. The first program creates a DynamoDB table named `TryDaxGoTable`. The second program writes data to the table.

   ```
   go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go -
   service dynamodb -command create-table
   ```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go -
service dynamodb -command put-item
```

4. Run the following Golang programs.

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go -
service dynamodb -command get-item
```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go -
service dynamodb -command query
```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go -
service dynamodb -command scan
```

   Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

5. In the previous step, you ran the programs against the DynamoDB endpoint. Now, run the programs again, but this time, the `GetItem`, `Query`, and `Scan` operations are processed by your DAX cluster.

   To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

     ```
     dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
     ```

   - **Using the AWS CLI** — Enter the following command.

     ```
     aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
     ```

     The cluster endpoint is shown in the output, as in the following example.

     ```
     {
         "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
         "Port": 8111,
         "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
     ```

```
}
```

Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go
 -service dax -command get-item -endpoint my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com:8111
```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go
 -service dax -command query -endpoint my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com:8111
```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go
 -service dax -command scan -endpoint my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com:8111
```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go
 -service dax -command paginated-scan -endpoint my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com:8111
```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go
 -service dax -command paginated-query -endpoint my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com:8111
```

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go
 -service dax -command paginated-batch-get -endpoint my-cluster.l6fzcv.dax-
clusters.us-east-1.amazonaws.com:8111
```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

6. Run the following Golang program to delete `TryDaxGoTable`.

```
go run ~/go/pkg/mod/github.com/aws-samples/sample-aws-dax-go-v2@v1.0.0/try_dax.go -
service dynamodb -command delete-table
```

Features not in parity with AWS SDK for Go V2

Middleware Stack – DAX Go V2 doesn't support the use of Middleware Stacks through APIoptions. For more information, see Customizing the AWS SDK for Go v2 Client Requests with Middleware.

Example:

```
// Custom middleware implementation
type customSerializeMiddleware struct{}
// ID returns the identifier for the middleware
func (m *customSerializeMiddleware) ID() string {
    return "CustomMiddleware"
}
// HandleSerialize implements the serialize middleware handler
func (m *customSerializeMiddleware) HandleSerialize(
    ctx context.Context,
    in middleware.SerializeInput,
    next middleware.SerializeHandler,
) (
    out middleware.SerializeOutput,
    metadata middleware.Metadata,
    err error,
) {
    // Add your custom logic here before the request is serialized
    fmt.Printf("Executing custom middleware for request: %v\n", in)
    // Call the next handler in the middleware chain
    return next.HandleSerialize(ctx, in)
}

func executeGetItem(ctx context.Context) error {
    client, err := initItemClient(ctx)
    if err != nil {
        os.Stderr.WriteString(fmt.Sprintf("failed to initialize client: %v\n", err))
        return err
    }

    st := time.Now()
    for c := 0; c < iterations; c++ {
        for i := 0; i < pkMax; i++ {
            for j := 0; j < skMax; j++ {
                // Create key using attributevalue.Marshal for type safety
                pk, err := attributevalue.Marshal(fmt.Sprintf("%s_%d", keyPrefix, i))
                if err != nil {
                    return fmt.Errorf("error marshaling pk: %v", err)
```

```
                }
                sk, err := attributevalue.Marshal(fmt.Sprintf("%d", j))
                if err != nil {
                    return fmt.Errorf("error marshaling sk: %v", err)
                }
                key := map[string]types.AttributeValue{
                    "pk": pk,
                    "sk": sk,
                }
                in := &dynamodb.GetItemInput{
                    TableName: aws.String(table),
                    Key:       key,
                }

                // Custom middleware option
                customMiddleware := func(o *dynamodb.Options) {
                    o.APIOptions = append(o.APIOptions, func(stack *middleware.Stack)
 error {
                        // Add custom middleware to the stack
                        return stack.Serialize.Add(&customSerializeMiddleware{},
 middleware.After)
                    })
                }

                // Apply options to the GetItem call
                out, err := client.GetItem(ctx, in, customMiddleware)
                if err != nil {
                    return err
                }
                writeVerbose(out)
            }
        }
    }
    d := time.Since(st)
    os.Stdout.WriteString(fmt.Sprintf("Total Time: %v, Avg Time: %v\n", d, d/
iterations))
    return nil
}
```

Output:

```
failed to execute command: custom middleware through APIOptions is not supported in DAX
 client
```

```
exit status 1
```

Default client configuration for Go

This guide will walk you through the configuration options that allow you to fine-tune your DAX client's performance, connection management, and logging behavior. By understanding the default settings and how to customize them, you can optimize your Go application's interaction with DAX.

In this section

- DAX Go SDK Client Defaults
- Client creation

DAX Go SDK Client Defaults

Parameter	Type	Description
`Region` required	`string`	The AWS Region to use for the DAX client (example- 'us-east-1'). This is a required parameter if not provided through the environment.
`HostPorts` required	`[] string`	List of DAX cluster endpoints to which SDK connects. For example: Non-Encrypted – dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com Encrypted – daxs://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
`MaxPendingConnectionsPerHost` default 10	`number`	Number of concurrent connection attempts. (Connections can be in the

Parameter	Type	Description
		process of being established concurrently.)
`ClusterUpdateThreshold` default 125 * time.Millisecond	`time.Duration`	The minimum time that must elapse between cluster refreshes.
`ClusterUpdateInterval` default 4 * time.Second	`time.Duration`	The interval at which the client will automatically refresh the DAX cluster information.
`IdleConnectionsReapDelay` default 30 * time.Second	`time.Duration`	The interval at which the client will close idle connections in the DAX client.
`ClientHealthCheckInterval` default 5 * time.Second	`time.Duration`	The interval at which the client will perform health checks on the DAX cluster endpoints.
`Credentials` default	`aws.CredentialsProvider`	The AWS credentials used by the DAX client to authenticate requests to the DAX service. See Credentials and Credential Providers.
`DialContext` default	`func`	A custom function used by the DAX client to establish connections to the DAX cluster.

Parameter	Type	Description
`SkipHostnameVerification` default false	bool	Skip hostname verification of TLS connections. This setting only affects encrypted clusters. When set to True, it disables hostname verification. Disabling verification means you can't authenticate the identity of the cluster you're connecting to, which poses security risks. By default, hostname verification is enabled.
`RouteManagerEnabled` default false	`bool`	This flag is used to remove routes facing network errors.
`RequestTimeout` default 60 * time.Second	`time.Duration`	This defines the maximum time the client will wait for a response from DAX. Priority: Context timeout (if set) > `RequestTimmeout` (if set) > Default 60s `RequestTimeout` .
`WriteRetries` default 2	`number`	The number of retries to attempt for write requests that fail.
`ReadRetries` default 2	`number`	The number of retries to attempt for read requests that fail.

Parameter	Type	Description
`RetryDelay` default 0	`time.Duration`	The delay for non-throttled errors (in seconds) for retry attempts when a request fails.
`Logger` optional	`logging.Logger`	Logger is an interface for logging entries at certain classifications.
`LogLevel` default utils.LogOff	`number`	This loglevel is defined for DAX only. It can be imported using github.com/aws/aws-dax-go-v2/tree/main/dax/utils. `const ( LogOff LogLevelType = 0 LogDebug LogLevelType = 1 LogDebugWithRequestRetries LogLevelType = 2 )`

Note

For `time.Duration`, the default unit is nanosecond. If we don't specify any unit for any parameter then it will consider that as nano seconds: `daxCfg.ClusterUpdateInterval = 10` means 10 nano seconds. (`daxCfg.ClusterUpdateInterval = 10 * time.Millisecond` means 10 milliseconds).

Client creation

To create a DAX client:

- Create DAX config, then create DAX client using DAX config. Using this, you can overwrite a DAX configuration if required.

```
import (
"github.com/aws/aws-dax-go-v2/dax/utils"
"github.com/aws/aws-dax-go-v2/dax"
)

// Non - Encrypted : 'dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com'.
// Encrypted : daxs://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com'.

config := dax.DefaultConfig()
config.HostPorts = []string{endpoint}
config.Region = region
config.LogLevel = utils.LogDebug
daxClient, err := dax.New(config)
```

Migrating to DAX Go SDK V2

This migration guide will help you transition your existing DAX Go applications.

V1 DAX Go SDK usage

```
package main

import (
    "fmt"
    "os"

    "github.com/aws/aws-dax-go/dax"
    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/dynamodb"
)

func main() {
    region := "us-west-2"
    endpoint := "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
```

```
    // Create session
    sess, err := session.NewSession(&aws.Config{
        Region: aws.String(region),
    })
    if err != nil {
        fmt.Printf("Failed to create session: %v\n", err)
        os.Exit(1)
    }

    // Configure DAX client
    cfg := dax.DefaultConfig()
    cfg.HostPorts = []string{endpoint}
    cfg.Region = region

    // Create DAX client
    daxClient, err := dax.New(cfg)
    if err != nil {
        fmt.Printf("Failed to create DAX client: %v\n", err)
        os.Exit(1)
    }
    defer daxClient.Close() // Don't forget to close the client

    // Create GetItem input
    input := &dynamodb.GetItemInput{
        TableName: aws.String("TryDaxTable"),
        Key: map[string]*dynamodb.AttributeValue{
            "pk": {
                N: aws.String("1"),
            },
            "sk": {
                N: aws.String("1"),
            },
        },
    }

    // Make the GetItem call
    result, err := daxClient.GetItem(input)
    if err != nil {
        fmt.Printf("Failed to get item: %v\n", err)
        os.Exit(1)
    }

    // Print the result
```

```
    fmt.Printf("GetItem succeeded: %+v\n", result)
}
```

V2 DAX Go SDK usage

```
package main

import (
    "context"
    "fmt"
    "os"

    "github.com/aws/aws-dax-go-v2/dax"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/dynamodb"
    "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
    "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
    "github.com/aws/aws-sdk-go-v2/aws"
)

func main() {
    ctx := context.Background()
    region := "us-west-2"
    endpoint := "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"

    // Create DAX config
    config := dax.DefaultConfig()
    // Specify Endpoint and Region
    config.HostPorts = []string{endpoint}
    config.Region = region
    // Enabling logging
    config.LogLevel = utils.LogDebug
    // Create DAX client
    daxClient, err := dax.New(config)
    if err != nil {
        fmt.Printf("Failed to create DAX client: %v\n", err)
        os.Exit(1)
    }
    defer daxClient.Close() // Don't forget to close the client

    // Create key using attributevalue.Marshal for type safety
    pk, err := attributevalue.Marshal(fmt.Sprintf("%s_%d", keyPrefix, i))
    if err != nil {
```

```
        return fmt.Errorf("error marshaling pk: %v", err)
    }
    sk, err := attributevalue.Marshal(fmt.Sprintf("%d", j))
    if err != nil {
        return fmt.Errorf("error marshaling sk: %v", err)
    }

    // Create GetItem input
    input := &dynamodb.GetItemInput{
        TableName: aws.String("TryDaxTable"),
        Key: map[string]types.AttributeValue{
             "pk": pk,
             "sk": sk,
        },
    }

    // Make the GetItem call
    result, err := daxClient.GetItem(ctx, input)
    if err != nil {
        fmt.Printf("Failed to get item: %v\n", err)
        os.Exit(1)
    }

    // Print the result
    fmt.Printf("GetItem succeeded: %+v\n", result)
}
```

For more API usage details, see AWS samples.

Java and DAX

DAX SDK for Java 2.x is compatible with AWS SDK for Java 2.x. It's built on top of Java 8+ and includes support for non-blocking I/O. For information about using DAX with AWS SDK for Java 1.x, see Using DAX with AWS SDK for Java 1.x.

Using the client as a Maven dependency

Follow these steps to use the client for the DAX SDK for Java in your application as a dependency.

1. Download and install Apache Maven. For more information, see Downloading Apache Maven and Installing Apache Maven.
2. Add the client Maven dependency to your application's Project Object Model (POM) file. In this example, replace *x.x.x* with the actual version number of the client.

```
<!--Dependency:-->
<dependencies>
    <dependency>
        <groupId>software.amazon.dax</groupId>
        <artifactId>amazon-dax-client</artifactId>
        <version>x.x.x</version>
    </dependency>
</dependencies>
```

TryDax sample code

After you've set up your workspace and added the DAX SDK as a dependency, copy TryDax.java into your project.

Run the code using this command.

```
java -cp classpath TryDax
```

You should see output similar to the following.

```
Creating a DynamoDB client

Attempting to create table; please wait...
Successfully created table.  Table status: ACTIVE
Writing data to the table...
Writing 10 items for partition key: 1
Writing 10 items for partition key: 2
Writing 10 items for partition key: 3
...

Running GetItem and Query tests...
First iteration of each test will result in cache misses
Next iterations are cache hits

GetItem test - partition key 1-100 and sort keys 1-10
  Total time: 4390.240 ms - Avg time: 4.390 ms
  Total time: 3097.089 ms - Avg time: 3.097 ms
  Total time: 3273.463 ms - Avg time: 3.273 ms
  Total time: 3353.739 ms - Avg time: 3.354 ms
  Total time: 3533.314 ms - Avg time: 3.533 ms
```

```
Query test - partition key 1-100 and sort keys between 2 and 9
  Total time: 475.868 ms - Avg time: 4.759 ms
  Total time: 423.333 ms - Avg time: 4.233 ms
  Total time: 460.271 ms - Avg time: 4.603 ms
  Total time: 397.859 ms - Avg time: 3.979 ms
  Total time: 466.644 ms - Avg time: 4.666 ms

Attempting to delete table; please wait...
Successfully deleted table.
```

Take note of the timing information—the number of milliseconds required for the `GetItem` and `Query` tests. In this case, you ran the program against the DynamoDB endpoint. Now you'll run the program again, this time against your DAX cluster.

To determine the endpoint of your DAX cluster, choose one of the following:

- In the DynamoDB console, select your DAX cluster. The cluster endpoint is shown in the console, as in the following example.

  ```
  dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
  ```

- Using the AWS CLI, enter the following command:

  ```
  aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
  ```

  The cluster endpoint address, port, and URL are shown in the output, as in the following example.

  ```
  {
      "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
      "Port": 8111,
      "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
  }
  ```

Now run the program again, but this time, specify the cluster endpoint URL as a command line parameter.

```
java -cp classpath TryDax dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
```

Look at the output and take note of the timing information. The elapsed times for `GetItem`and `Query` should be significantly lower with DAX than with DynamoDB.

SDK metrics

With DAX SDK for Java 2.x, you can collect metrics about the service clients in your application and analyze the output in Amazon CloudWatch. See Enabling SDK metrics for more information.

> **Note**
>
> The DAX SDK for Java only collects `ApiCallSuccessful` and `ApiCallDuration` metrics.

        System.out.println("Query test - partition key 1-" + pk + " and sort keys
between " + sk1 + " and " + sk2);

        for (int i = 0; i < iterations; i++) {
            startTime = System.nanoTime();
            for (int ipk = 1; ipk <= pk; ipk++) {
                try {
                    // Pagination API for Query.
                    client.queryPaginator(QueryRequest.builder()
                            .tableName(tableName)
                            .keyConditionExpression("pk = :pkval and sk between :skval1
and :skval2")
                            .expressionAttributeValues(Map.of(":pkval", attr(ipk),
":skval1", attr(sk1), ":skval2", attr(sk2)))
                            .build()).items().subscribe((item) -> {
                    }).get();
                } catch (Exception e) {
                    System.err.println("Unable to query table:");
                    e.printStackTrace();
                }
            }
            endTime = System.nanoTime();
            printTime(startTime, endTime, pk);
        }
    }
```

```
    private static void printTime(long startTime, long endTime, int iterations) {
        System.out.format("\tTotal time: %.3f ms - ", (endTime - startTime) /
 (1000000.0));
        System.out.format("Avg time: %.3f ms\n", (endTime - startTime) / (iterations *
 1000000.0));
    }
}
```

.NET and DAX

Follow these steps to run the .NET sample on your Amazon EC2 instance.

> **Note**
>
> This tutorial uses the .NET 9 SDK. It shows how you can run a program in your default Amazon VPC to access your Amazon DynamoDB Accelerator (DAX) cluster. It works with the AWS SDK v4 for .NET . For details about changes in V4 and information about migrating, see Migrating to version 4 of the AWS SDK for .NET. If you prefer, you can use the AWS Toolkit for Visual Studio to write a .NET application and deploy it into your VPC. For more information, see Creating and Deploying Elastic Beanstalk Applications in .NET Using AWS Toolkit for Visual Studio in the *AWS Elastic Beanstalk Developer Guide*.

To run the .NET sample for DAX

1. Go to the Microsoft Downloads page and download the latest .NET 9 SDK for Linux. The downloaded file is `dotnet-sdk-N.N.N-linux-x64.tar.gz`.
2. Extract the SDK files.

   ```
   mkdir dotnet
   tar zxvf dotnet-sdk-N.N.N-linux-x64.tar.gz -C dotnet
   ```

   Replace *N.N.N* with the actual version number of the .NET SDK (for example: `9.0.305`).
3. Verify the installation.

   ```
   alias dotnet=$HOME/dotnet/dotnet
   dotnet --version
   ```

This should print the version number of the .NET SDK.

> **Note**
>
> Instead of the version number, you might receive the following error:
> error: libunwind.so.8: cannot open shared object file: No such file or directory
> To resolve the error, install the `libunwind` package.
>
> ```
> sudo yum install -y libunwind
> ```
>
> After you do this, you should be able to run the `dotnet --version` command without any errors.

4. Create a new .NET project.

```
dotnet new console -o myApp
```

This requires a few minutes to perform a one-time-only setup. When it is complete, run the sample project.

```
dotnet run --project myApp
```

You should receive the following message: `Hello World!`

5. The `myApp/myApp.csproj` file contains metadata about your project. To use the DAX client in your application, modify the file so that it looks like the following.

```
<Project Sdk="Microsoft.NET.Sdk">
    <PropertyGroup>
        <OutputType>Exe</OutputType>
        <TargetFramework>net9.0</TargetFramework>
    </PropertyGroup>
    <ItemGroup>
        <PackageReference Include="AWSSDK.DAX.Client" Version="*" />
    </ItemGroup>
</Project>
```

6. Download the sample program source code (`.zip` file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

7. Now run the sample programs of *dotNet*, one at a time. For each program, copy its contents into the `myApp/Program.cs`, and then run the `MyApp` project.

   Run the following .NET programs. The first program creates a DynamoDB table named `TryDaxTable`. The second program writes data to the table.

```
cp TryDax/dotNet/01-CreateTable.cs myApp/Program.cs
dotnet run --project myApp

cp TryDax/dotNet/02-Write-Data.cs myApp/Program.cs
dotnet run --project myApp
```

8. Next, run some programs to perform `GetItem`, `Query`, and `Scan` operations on your DAX cluster. To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
```

   - **Using the AWS CLI** — Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

     The cluster endpoint is shown in the output, as in the following example.

```
{
    "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
    "Port": 8111,
    "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
}
```

Now run the following programs, specifying your cluster endpoint as a command line parameter. (Replace the sample endpoint with your actual DAX cluster endpoint.)

```
cp TryDax/dotNet/03-GetItem-Test.cs myApp/Program.cs
dotnet run --project myApp dax://my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com

cp TryDax/dotNet/04-Query-Test.cs myApp/Program.cs
dotnet run --project myApp dax://my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com

cp TryDax/dotNet/05-Scan-Test.cs myApp/Program.cs
dotnet run --project myApp dax://my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

9. Run the following .NET program to delete `TryDaxTable`.

```
cp TryDax/dotNet/06-DeleteTable.cs myApp/Program.cs
dotnet run --project myApp
```

For more information about these programs, see the following sections:

- 01-CreateTable.cs
- 02-Write-Data.cs
- 03-GetItem-Test.cs
- 04-Query-Test.cs
- 05-Scan-Test.cs
- 06-DeleteTable.cs

01-CreateTable.cs

The `01-CreateTable.cs` program creates a table (`TryDaxTable`). The remaining .NET programs in this section depend on this table.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            AmazonDynamoDBClient client = new AmazonDynamoDBClient();

            var tableName = "TryDaxTable";

            var request = new CreateTableRequest()
            {
                TableName = tableName,
                KeySchema = new List<KeySchemaElement>()
                {
                    new KeySchemaElement{ AttributeName = "pk",KeyType = "HASH"},
                    new KeySchemaElement{ AttributeName = "sk",KeyType = "RANGE"}
                },
                AttributeDefinitions = new List<AttributeDefinition>() {
                    new AttributeDefinition{ AttributeName = "pk",AttributeType = "N"},
                    new AttributeDefinition{ AttributeName = "sk",AttributeType  = "N"}
                },
                ProvisionedThroughput = new ProvisionedThroughput()
                {
                    ReadCapacityUnits = 10,
                    WriteCapacityUnits = 10
                }
            };

            var response = await client.CreateTableAsync(request);

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

02-Write-Data.cs

The `02-Write-Data.cs` program writes test data to `TryDaxTable`.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            AmazonDynamoDBClient client = new AmazonDynamoDBClient();

            var tableName = "TryDaxTable";

            string someData = new string('X', 1000);
            var pkmax = 10;
            var skmax = 10;

            for (var ipk = 1; ipk <= pkmax; ipk++)
            {
                Console.WriteLine($"Writing {skmax} items for partition key: {ipk}");
                for (var isk = 1; isk <= skmax; isk++)
                {
                    var request = new PutItemRequest()
                    {
                        TableName = tableName,
                        Item = new Dictionary<string, AttributeValue>()
                       {
                            { "pk", new AttributeValue{N = ipk.ToString() } },
                            { "sk", new AttributeValue{N = isk.ToString() } },
                            { "someData", new AttributeValue{S = someData } }
                       }
                    };

                    var response = await client.PutItemAsync(request);
```

```
                }
            }

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

03-GetItem-Test.cs

The `03-GetItem-Test.cs` program performs `GetItem` operations on `TryDaxTable`.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.DAX;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            string endpointUri = args[0];
            Console.WriteLine($"Using DAX client - endpointUri={endpointUri}");

            var clientConfig = new DaxClientConfig(endpointUri)
            {
                AwsCredentials = FallbackCredentialsFactory.GetCredentials()
            };
            var client = new ClusterDaxClient(clientConfig);

            var tableName = "TryDaxTable";

            var pk = 1;
            var sk = 10;
            var iterations = 5;

            var startTime = System.DateTime.Now;
```

```
            for (var i = 0; i < iterations; i++)
            {
                for (var ipk = 1; ipk <= pk; ipk++)
                {
                    for (var isk = 1; isk <= sk; isk++)
                    {
                        var request = new GetItemRequest()
                        {
                            TableName = tableName,
                            Key = new Dictionary<string, AttributeValue>() {
                            {"pk", new AttributeValue {N = ipk.ToString()} },
                            {"sk", new AttributeValue {N = isk.ToString() } }
                        }
                        };
                        var response = await client.GetItemAsync(request);
                        Console.WriteLine($"GetItem succeeded for pk: {ipk},sk:
 {isk}");
                    }
                }
            }

            var endTime = DateTime.Now;
            TimeSpan timeSpan = endTime - startTime;
            Console.WriteLine($"Total time: {timeSpan.TotalMilliseconds}
 milliseconds");

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

04-Query-Test.cs

The `04-Query-Test.cs` program performs `Query` operations on `TryDaxTable`.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.Runtime;
using Amazon.DAX;
```

```
using Amazon.DynamoDBv2.Model;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            string endpointUri = args[0];
            Console.WriteLine($"Using DAX client - endpointUri={endpointUri}");

            var clientConfig = new DaxClientConfig(endpointUri)
            {
                AwsCredentials = FallbackCredentialsFactory.GetCredentials()
            };
            var client = new ClusterDaxClient(clientConfig);

            var tableName = "TryDaxTable";

            var pk = 5;
            var sk1 = 2;
            var sk2 = 9;
            var iterations = 5;

            var startTime = DateTime.Now;

            for (var i = 0; i < iterations; i++)
            {
                var request = new QueryRequest()
                {
                    TableName = tableName,
                    KeyConditionExpression = "pk = :pkval and sk between :skval1
 and :skval2",
                    ExpressionAttributeValues = new Dictionary<string,
 AttributeValue>() {
                            {":pkval", new AttributeValue {N = pk.ToString()} },
                            {":skval1", new AttributeValue {N = sk1.ToString()} },
                            {":skval2", new AttributeValue {N = sk2.ToString()} }
                    }
                };
                var response = await client.QueryAsync(request);
                Console.WriteLine($"{i}: Query succeeded");
```

```
            }

            var endTime = DateTime.Now;
            TimeSpan timeSpan = endTime - startTime;
            Console.WriteLine($"Total time: {timeSpan.TotalMilliseconds}
 milliseconds");

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

05-Scan-Test.cs

The `05-Scan-Test.cs` program performs `Scan` operations on `TryDaxTable`.

```
using System;
using System.Threading.Tasks;
using Amazon.Runtime;
using Amazon.DAX;
using Amazon.DynamoDBv2.Model;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            string endpointUri = args[0];
            Console.WriteLine($"Using DAX client - endpointUri={endpointUri}");

            var clientConfig = new DaxClientConfig(endpointUri)
            {
                AwsCredentials = FallbackCredentialsFactory.GetCredentials()
            };
            var client = new ClusterDaxClient(clientConfig);

            var tableName = "TryDaxTable";

            var iterations = 5;
```

```
            var startTime = DateTime.Now;

            for (var i = 0; i < iterations; i++)
            {
                var request = new ScanRequest()
                {
                    TableName = tableName
                };
                var response = await client.ScanAsync(request);
                Console.WriteLine($"{i}: Scan succeeded");
            }

            var endTime = DateTime.Now;
            TimeSpan timeSpan = endTime - startTime;
            Console.WriteLine($"Total time: {timeSpan.TotalMilliseconds}
 milliseconds");

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

06-DeleteTable.cs

The `06-DeleteTable.cs` program deletes `TryDaxTable`. Run this program after you have finished testing.

```
using System;
using System.Threading.Tasks;
using Amazon.DynamoDBv2.Model;
using Amazon.DynamoDBv2;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            AmazonDynamoDBClient client = new AmazonDynamoDBClient();
```

```
            var tableName = "TryDaxTable";

            var request = new DeleteTableRequest()
            {
                TableName = tableName
            };

            var response = await client.DeleteTableAsync(request);

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

Python and DAX

Follow this procedure to run the Python sample application on your Amazon EC2 instance.

To run the Python sample for DAX

1. Install the DAX Python client using the `pip` utility.

   ```
   pip install amazon-dax-client
   ```

2. Download the sample program source code (`.zip` file).

   ```
   wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
   TryDax.zip
   ```

   When the download is complete, extract the source files.

   ```
   unzip TryDax.zip
   ```

3. Run the following Python programs. The first program creates an Amazon DynamoDB table named `TryDaxTable`. The second program writes data to the table.

   ```
   python 01-create-table.py
   python 02-write-data.py
   ```

4. Run the following Python programs.

```
python 03-getitem-test.py
python 04-query-test.py
python 05-scan-test.py
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

5. In the previous step, you ran the programs against the DynamoDB endpoint. Now run the programs again, but this time, the `GetItem`, `Query`, and `Scan` operations are processed by your DAX cluster.

   To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

     ```
     dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
     ```

   - **Using the AWS CLI** — Enter the following command.

     ```
     aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
     ```

     The cluster endpoint is shown in the output, as in this example.

     ```
     {
         "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
         "Port": 8111,
         "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
     }
     ```

   Run the programs again, but this time, specify the cluster endpoint as a command line parameter.

   ```
   python 03-getitem-test.py dax://my-cluster.l6fzcv.dax-clusters.us-
   east-1.amazonaws.com
   python 04-query-test.py dax://my-cluster.l6fzcv.dax-clusters.us-
   east-1.amazonaws.com
   python 05-scan-test.py dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
   ```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

6. Run the following Python program to delete `TryDaxTable`.

```
python 06-delete-table.py
```

For more information about these programs, see the following sections:

- 01-create-table.py
- 02-write-data.py
- 03-getitem-test.py
- 04-query-test.py
- 05-scan-test.py
- 06-delete-table.py

01-create-table.py

The `01-create-table.py` program creates a table (`TryDaxTable`). The remaining Python programs in this section depend on this table.

```
import boto3

def create_dax_table(dyn_resource=None):
    """
    Creates a DynamoDB table.

    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The newly created table.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table_name = "TryDaxTable"
    params = {
        "TableName": table_name,
        "KeySchema": [
```

```
            {"AttributeName": "partition_key", "KeyType": "HASH"},
            {"AttributeName": "sort_key", "KeyType": "RANGE"},
        ],
        "AttributeDefinitions": [
            {"AttributeName": "partition_key", "AttributeType": "N"},
            {"AttributeName": "sort_key", "AttributeType": "N"},
        ],
        "BillingMode": "PAY_PER_REQUEST",
    }
    table = dyn_resource.create_table(**params)
    print(f"Creating {table_name}...")
    table.wait_until_exists()
    return table

if __name__ == "__main__":
    dax_table = create_dax_table()
    print(f"Created table.")
```

02-write-data.py

The `02-write-data.py` program writes test data to `TryDaxTable`.

```
import boto3

def write_data_to_dax_table(key_count, item_size, dyn_resource=None):
    """
    Writes test data to the demonstration table.

    :param key_count: The number of partition and sort keys to use to populate the
                      table. The total number of items is key_count * key_count.
    :param item_size: The size of non-key data for each test item.
    :param dyn_resource: Either a Boto3 or DAX resource.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    some_data = "X" * item_size

    for partition_key in range(1, key_count + 1):
        for sort_key in range(1, key_count + 1):
            table.put_item(
```

```
                Item={
                    "partition_key": partition_key,
                    "sort_key": sort_key,
                    "some_data": some_data,
                }
            )
            print(f"Put item ({partition_key}, {sort_key}) succeeded.")

if __name__ == "__main__":
    write_key_count = 10
    write_item_size = 1000
    print(
        f"Writing {write_key_count*write_key_count} items to the table. "
        f"Each item is {write_item_size} characters."
    )
    write_data_to_dax_table(write_key_count, write_item_size)
```

03-getitem-test.py

The `03-getitem-test.py` program performs `GetItem` operations on `TryDaxTable`. This example is given for the Region eu-west-1.

```
import argparse
import sys
import time
import amazondax
import boto3

def get_item_test(key_count, iterations, dyn_resource=None):
    """
    Gets items from the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param key_count: The number of items to get from the table in each iteration.
    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.
    """
    if dyn_resource is None:
```

```
        dyn_resource = boto3.resource('dynamodb')

    table = dyn_resource.Table('TryDaxTable')
    start = time.perf_counter()
    for _ in range(iterations):
        for partition_key in range(1, key_count + 1):
            for sort_key in range(1, key_count + 1):
                table.get_item(Key={
                    'partition_key': partition_key,
                    'sort_key': sort_key
                })
                print('.', end='')
                sys.stdout.flush()
    print()
    end = time.perf_counter()
    return start, end

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument(
        'endpoint_url', nargs='?',
        help="When specified, the DAX cluster endpoint. Otherwise, DAX is not used.")
    args = parser.parse_args()

    test_key_count = 10
    test_iterations = 50
    if args.endpoint_url:
        print(f"Getting each item from the table {test_iterations} times, "
              f"using the DAX client.")
        # Use a with statement so the DAX client closes the cluster after completion.
        with amazondax.AmazonDaxClient.resource(endpoint_url=args.endpoint_url,
 region_name='eu-west-1') as dax:
            test_start, test_end = get_item_test(
                test_key_count, test_iterations, dyn_resource=dax)
    else:
        print(f"Getting each item from the table {test_iterations} times, "
              f"using the Boto3 client.")
        test_start, test_end = get_item_test(
            test_key_count, test_iterations)
    print(f"Total time: {test_end - test_start:.4f} sec. Average time: "
          f"{(test_end - test_start)/ test_iterations}.")
```

04-query-test.py

The `04-query-test.py` program performs `Query` operations on `TryDaxTable`.

```
import argparse
import time
import sys
import amazondax
import boto3
from boto3.dynamodb.conditions import Key

def query_test(partition_key, sort_keys, iterations, dyn_resource=None):
    """
    Queries the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param partition_key: The partition key value to use in the query. The query
                          returns items that have partition keys equal to this value.
    :param sort_keys: The range of sort key values for the query. The query returns
                      items that have sort key values between these two values.
    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    key_condition_expression = Key("partition_key").eq(partition_key) & Key(
        "sort_key"
    ).between(*sort_keys)

    start = time.perf_counter()
    for _ in range(iterations):
        table.query(KeyConditionExpression=key_condition_expression)
        print(".", end="")
        sys.stdout.flush()
    print()
    end = time.perf_counter()
    return start, end
```

```
if __name__ == "__main__":
    # pylint: disable=not-context-manager
    parser = argparse.ArgumentParser()
    parser.add_argument(
        "endpoint_url",
        nargs="?",
        help="When specified, the DAX cluster endpoint. Otherwise, DAX is not used.",
    )
    args = parser.parse_args()

    test_partition_key = 5
    test_sort_keys = (2, 9)
    test_iterations = 100
    if args.endpoint_url:
        print(f"Querying the table {test_iterations} times, using the DAX client.")
        # Use a with statement so the DAX client closes the cluster after completion.
        with amazondax.AmazonDaxClient.resource(endpoint_url=args.endpoint_url) as dax:
            test_start, test_end = query_test(
                test_partition_key, test_sort_keys, test_iterations, dyn_resource=dax
            )
    else:
        print(f"Querying the table {test_iterations} times, using the Boto3 client.")
        test_start, test_end = query_test(
            test_partition_key, test_sort_keys, test_iterations
        )

    print(
        f"Total time: {test_end - test_start:.4f} sec. Average time: "
        f"{(test_end - test_start)/test_iterations}."
    )
```

05-scan-test.py

The `05-scan-test.py` program performs `Scan` operations on `TryDaxTable`.

```
import argparse
import time
import sys
import amazondax
import boto3

def scan_test(iterations, dyn_resource=None):
    """
```

```
    Scans the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    start = time.perf_counter()
    for _ in range(iterations):
        table.scan()
        print(".", end="")
        sys.stdout.flush()
    print()
    end = time.perf_counter()
    return start, end

if __name__ == "__main__":
    # pylint: disable=not-context-manager
    parser = argparse.ArgumentParser()
    parser.add_argument(
        "endpoint_url",
        nargs="?",
        help="When specified, the DAX cluster endpoint. Otherwise, DAX is not used.",
    )
    args = parser.parse_args()

    test_iterations = 100
    if args.endpoint_url:
        print(f"Scanning the table {test_iterations} times, using the DAX client.")
        # Use a with statement so the DAX client closes the cluster after completion.
        with amazondax.AmazonDaxClient.resource(endpoint_url=args.endpoint_url) as dax:
            test_start, test_end = scan_test(test_iterations, dyn_resource=dax)
    else:
        print(f"Scanning the table {test_iterations} times, using the Boto3 client.")
        test_start, test_end = scan_test(test_iterations)
    print(
        f"Total time: {test_end - test_start:.4f} sec. Average time: "
        f"{(test_end - test_start)/test_iterations}."
```

```
    )
```

06-delete-table.py

The `06-delete-table.py` program deletes `TryDaxTable`. Run this program after you have finished testing Amazon DynamoDB Accelerator (DAX) functionality.

```
import boto3

def delete_dax_table(dyn_resource=None):
    """
    Deletes the demonstration table.

    :param dyn_resource: Either a Boto3 or DAX resource.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    table.delete()

    print(f"Deleting {table.name}...")
    table.wait_until_not_exists()

if __name__ == "__main__":
    delete_dax_table()
    print("Table deleted!")
```

Modifying an existing application to use DAX

If you already have a Java application that uses Amazon DynamoDB, you can modify it so that it can access your DynamoDB Accelerator (DAX) cluster. You don't have to rewrite the entire application because the DAX Java client is similar to the DynamoDB low-level client included in the AWS SDK for Java 2.x. See Working with items in DynamoDB for details.

> **Note**
>
> This example uses AWS SDK for Java 2.x. For the legacy SDK for Java 1.x version, see Modifying an existing SDK for Java 1.x application to use DAX.

To modify your program, replace the DynamoDB client with a DAX client.

```
Region region = Region.US_EAST_1;

// Create an asynchronous DynamoDB client
DynamoDbAsyncClient client = DynamoDbAsyncClient.builder()
                .region(region)
                .build();

// Create an asynchronous DAX client
DynamoDbAsyncClient client = ClusterDaxAsyncClient.builder()
                .overrideConfiguration(Configuration.builder()
                    .url(<cluster url>) // for example, "dax://my-cluster.l6fzcv.dax-
clusters.us-east-1.amazonaws.com"
                    .region(region)
                    .addMetricPublisher(cloudWatchMetricsPub) // optionally enable SDK
 metric collection
                    .build())
                .build();
```

You can also use the high-level library that is part of the AWS SDK for Java 2.x, replacing the DynamoDB client with a DAX client.

```
Region region = Region.US_EAST_1;
DynamoDbAsyncClient dax = ClusterDaxAsyncClient.builder()
        .overrideConfiguration(Configuration.builder()
            .url(<cluster url>) // for example, "dax://my-cluster.l6fzcv.dax-
clusters.us-east-1.amazonaws.com"
            .region(region)
            .build())
        .build();

DynamoDbEnhancedAsyncClient enhancedClient = DynamoDbEnhancedAsyncClient.builder()
        .dynamoDbClient(dax)
        .build();
```

For more information, see Mapping items in DynamoDB tables.

Managing DAX clusters

This section addresses some of the common management tasks for Amazon DynamoDB Accelerator (DAX) clusters.

Topics

- IAM permissions for managing a DAX cluster
- Scaling a DAX cluster
- Customizing DAX cluster settings
- Configuring TTL settings
- Tagging support for DAX
- AWS CloudTrail integration
- Deleting a DAX cluster

IAM permissions for managing a DAX cluster

When you administer a DAX cluster using the AWS Management Console or the AWS Command Line Interface (AWS CLI), we strongly recommend that you narrow the scope of actions that users can perform. By doing so, you help mitigate risk while following the principle of least privilege.

The following discussion focuses on access control for the DAX management APIs. For more information, see Amazon DynamoDB accelerator in the *Amazon DynamoDB API Reference*.

> **Note**
>
> For more detailed information about managing AWS Identity and Access Management (IAM) permissions, see the following:
>
> - IAM and creating DAX clusters: Creating a DAX cluster.
> - IAM and DAX data plane operations: DAX access control.

For the DAX management APIs, you can't scope API actions to a specific resource. The `Resource` element must be set to `"*"`. This is different from DAX data plane API operations, such as `GetItem`, `Query`, and `Scan`. Data plane operations are exposed through the DAX client, and those operations *can* be scoped to specific resources.

To illustrate, consider the following IAM policy document.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "dax:*"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
            ]
        }
    ]
}
```

Suppose that the intent of this policy is to allow DAX management API calls for the cluster `DAXCluster01`— and only that cluster.

Now suppose that a user issues the following AWS CLI command.

```
aws dax describe-clusters
```

This command fails with a Not Authorized exception because the underlying `DescribeClusters` API call can't be scoped to a specific cluster. Even though the policy is syntactically valid, the command fails because the `Resource` element must be set to `"*"`. However, if the user runs a program that sends DAX data plane calls (such as `GetItem` or `Query`) to `DAXCluster01`, those calls *do* succeed. This is because DAX data plane APIs can be scoped to specific resources (in this case, `DAXCluster01`).

If you want to write a single comprehensive IAM policy to encompass both DAX management APIs and DAX data plane APIs, we suggest that you include two distinct statements in the policy document. One of these statements should address the DAX data plane APIs, while the other statement addresses the DAX management APIs.

The following example policy shows this approach. Note how the `DAXDataAPIs` statement is scoped to the `DAXCluster01` resource, but the resource for `DAXManagementAPIs` must be `"*"`.

The actions shown in each statement are for illustration only. You can customize them as needed for your application.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DAXDataAPIs",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan",
                "dax:PutItem",
                "dax:UpdateItem",
                "dax:DeleteItem",
                "dax:BatchWriteItem"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
            ]},
            {
            "Sid": "DAXManagementAPIs",
            "Action": [
                "dax:CreateParameterGroup",
                "dax:CreateSubnetGroup",
                "dax:DecreaseReplicationFactor",
                "dax:DeleteCluster",
                "dax:DeleteParameterGroup",
                "dax:DeleteSubnetGroup",
                "dax:DescribeClusters",
                "dax:DescribeDefaultParameters",
                "dax:DescribeEvents",
                "dax:DescribeParameterGroups",
                "dax:DescribeParameters",
                "dax:DescribeSubnetGroups",
                "dax:IncreaseReplicationFactor",
                "dax:ListTags",
                "dax:RebootNode",
                "dax:TagResource",
```

```
                "dax:UntagResource",
                "dax:UpdateCluster",
                "dax:UpdateParameterGroup",
                "dax:UpdateSubnetGroup"
                ],
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
        }
    ]
}
```

Scaling a DAX cluster

There are two options available for scaling a DAX cluster. The first option is *horizontal scaling*, where you add read replicas to the cluster. The second option is *vertical scaling*, where you select different node types. For advice on how to approach choosing an appropriate cluster size and node type for your application, see DAX cluster sizing guide.

Horizontal scaling

With horizontal scaling, you can improve throughput for read operations by adding more read replicas to the cluster. A single DAX cluster supports up to 10 read replicas, and you can add or remove replicas while the cluster is running.

When you add a new node, you must synchronize the cache data from a peer node. Therefore, the addition time varies based on cache size and your application workload. As a best practice, we recommend that you pre-scale your cluster to meet expected traffic peaks. For information about right-sizing guidelines and monitoring recommendations, see DAX cluster sizing guide.

The following AWS CLI examples show how to increase or decrease the number of nodes. The `--new-replication-factor` argument specifies the total number of nodes in the cluster. One of the nodes is the primary node, and the other nodes are read replicas.

```
aws dax increase-replication-factor \
    --cluster-name MyNewCluster  \
    --new-replication-factor 5
```

```
aws dax decrease-replication-factor \
```

```
    --cluster-name MyNewCluster  \
    --new-replication-factor 3
```

> **Note**
>
> The cluster status changes to `modifying` when you modify the replication factor. The status changes to `available` when the modification is complete.

Vertical scaling

If you have a large working set of data, your application might benefit from using larger node types. Larger nodes can enable the cluster to store more data in memory, reducing cache misses and improving overall application performance of the application. (All of the nodes in a DAX cluster must be of the same type.)

If your DAX cluster has a high rate of write operations or cache misses, your application might also benefit from using larger node types. Write operations and cache misses consume resources on the cluster's primary node. Therefore, using larger node types might increase the performance of the primary node and thereby allow a higher throughput for these types of operations.

You can't modify the node types on a running DAX cluster. Instead, you must create a new cluster with the desired node type. For a list of supported node types, see Nodes.

You can create a new DAX cluster using the AWS Management Console, CloudFormation, the AWS CLI, or the AWS SDK. (For the AWS CLI, use the `--node-type` parameter to specify the node type.)

Customizing DAX cluster settings

When you create a DAX cluster, the following default settings are used:

- Automatic cache eviction enabled with Time to Live (TTL) of 5 minutes
- No preference for Availability Zones
- No preference for maintenance windows
- Notifications disabled

For new clusters, you can customize the settings at creation time. To do this in the AWS Management Console, clear **Use default settings** to modify the following settings:

- **Network and Security**—Allows you to run individual DAX cluster nodes in different Availability Zones within the current AWS Region. If you choose **No Preference**, the nodes are distributed among Availability Zones automatically.
- **Parameter Group**—A named set of parameters that are applied to every node in the cluster. You can use a parameter group to specify cache TTL behavior. You can change the value of any given parameter within a parameter group (except default parameter group `default.dax.1.0`) at any time.
- **Maintenance Window**—A weekly time period during which software upgrades and patches are applied to the nodes in the cluster. You can choose the start day, start time, and duration of the maintenance window. If you choose **No Preference**, the maintenance window is selected at random from an 8-hour block of time per Region. For more information, see Maintenance window.

> **Note**
>
> **Parameter Group** and **Maintenance Window** can also be changed at any time on a running cluster.

When a maintenance event occurs, DAX can notify you using Amazon Simple Notification Service (Amazon SNS). To configure notifications, choose an option from the **Topic for SNS notification** selector. You can create a new Amazon SNS topic, or use an existing topic.

For more information about setting up and subscribing to an Amazon SNS topic, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*.

Configuring TTL settings

DAX maintains two caches for data that it reads from DynamoDB:

- **Item cache**—For items retrieved using `GetItem` or `BatchGetItem`.
- **Query cache**—For result sets retrieved using `Query` or `Scan`.

For more information, see Item cache and Query cache.

The default TTL for each of these caches is 5 minutes. If you want to use different TTL settings, you can launch a DAX cluster using a custom parameter group. To do this on the console, choose **DAX | Parameter groups** in the navigation pane.

You can also perform these tasks using the AWS CLI. The following example shows how to launch a new DAX cluster using a custom parameter group. In this example, the item cache TTL is set to 10 minutes, and the query cache TTL is set to 3 minutes.

1. Create a new parameter group.

```
aws dax create-parameter-group \
    --parameter-group-name custom-ttl
```

2. Set the item cache TTL to 10 minutes (600000 milliseconds).

```
aws dax update-parameter-group \
    --parameter-group-name custom-ttl \
    --parameter-name-values "ParameterName=record-ttl-millis,ParameterValue=600000"
```

3. Set the query cache TTL to 3 minutes (180000 milliseconds).

```
aws dax update-parameter-group \
    --parameter-group-name custom-ttl \
    --parameter-name-values "ParameterName=query-ttl-millis,ParameterValue=180000"
```

4. Verify that the parameters have been set correctly.

```
aws dax describe-parameters --parameter-group-name custom-ttl \
    --query "Parameters[*].[ParameterName,Description,ParameterValue]"
```

You can now launch a new DAX cluster with this parameter group.

```
aws dax create-cluster \
    --cluster-name MyNewCluster \
    --node-type dax.r3.large \
    --replication-factor 3 \
    --iam-role-arn arn:aws:iam::123456789012:role/DAXServiceRole \
    --parameter-group custom-ttl
```

> **Note**
>
> You can modify a parameter group attached to a running DAX cluster. Parameter changes apply only to items written after the modification. Existing cached items retain the TTL and settings from when they were originally written.

Tagging support for DAX

Many AWS services, including DynamoDB, support *tagging*—the ability to label resources with user-defined names. You can assign tags to DAX clusters, allowing you to quickly identify all of your AWS resources that have the same tag, or to categorize your AWS bills by the tags you assign.

For more information, see Adding tags and labels to resources in DynamoDB.

Using the AWS Management Console

To manage DAX cluster tags

1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane, under **DAX**, choose **Clusters**.
3. Choose the cluster that you want to work with.
4. Choose the **Tags** tab. You can add, list, edit, or delete your tags here.

   When the settings are as you want them, choose **Apply Changes**.

Using the AWS CLI

When you use the AWS CLI to manage DAX cluster tags, you must first determine the Amazon Resource Name (ARN) for the cluster. The following example shows how to determine the ARN for a cluster named `MyDAXCluster`.

```
aws dax describe-clusters \
    --cluster-name MyDAXCluster \
    --query "Clusters[*].ClusterArn"
```

In the output, the ARN will look similar to this: `arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster`

The following example shows how to tag the cluster.

```
aws dax tag-resource  \
    --resource-name arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster \
    --tags="Key=ClusterUsage,Value=prod"
```

List all the tags for a cluster.

```
aws dax list-tags \
    --resource-name arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster
```

To remove a tag, specify its key.

```
aws dax untag-resource  \
    --resource-name arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster \
    --tag-keys ClusterUsage
```

AWS CloudTrail integration

DAX is integrated with AWS CloudTrail, allowing you to audit DAX cluster activities. You can use CloudTrail logs to view all the changes that have been made at the cluster level. You can also see changes to cluster components such as nodes, subnet groups, and parameter groups. For more information, see Logging DynamoDB operations by using AWS CloudTrail.

Deleting a DAX cluster

If you are no longer using a DAX cluster, you should delete it to avoid being charged for unused resources.

You can delete a DAX cluster using the console or the AWS CLI. The following is an example.

```
aws dax delete-cluster --cluster-name mydaxcluster
```

Monitoring DynamoDB Accelerator

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon DynamoDB Accelerator (DAX) and your AWS solutions. You should collect monitoring data

from all parts of your AWS solution so that you can more easily debug a multi-point failure, if one occurs.

Before you start monitoring DAX, you should create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

Topics

- Monitoring tools for DynamoDB Accelerator
- Monitoring with Amazon CloudWatch
- Logging DAX operations using AWS CloudTrail

Monitoring tools for DynamoDB Accelerator

AWS provides tools that you can use to monitor Amazon DynamoDB Accelerator (DAX). You can configure some of these tools to do the monitoring for you, and some require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Topics

- Automated monitoring tools
- Manual monitoring tools

Automated monitoring tools

You can use the following automated monitoring tools to watch DAX and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over

a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring metrics in DynamoDB with Amazon CloudWatch.

- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see Monitoring Log Files in the *Amazon CloudWatch User Guide*.
- **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see What is Amazon CloudWatch Events in the *Amazon CloudWatch User Guide*.
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Working with CloudTrail Log Files in the *AWS CloudTrail User Guide*.

Manual monitoring tools

Another important part of monitoring DAX involves manually monitoring those items that the CloudWatch alarms don't cover. The DAX, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on DAX.

- The DAX dashboard shows the following:
  - Service health
- The CloudWatch home page shows the following:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

  In addition, you can use CloudWatch to do the following:
  - Create customized dashboards to monitor the services that you care about.
  - Graph metric data to troubleshoot issues and discover trends.
  - Search and browse all of your AWS resource metrics.
  - Create and edit alarms to be notified of problems.

Monitoring with Amazon CloudWatch

You can monitor DynamoDB Accelerator (DAX) using Amazon CloudWatch, which collects and processes raw data from DAX into readable, near real-time metrics. These statistics are recorded for a period of two weeks. You can then access historical information for a better perspective on how your web application or service is performing. By default, DAX metric data is sent to CloudWatch automatically. For more information, see What Is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*.

Topics

- How do I use DAX metrics?
- Viewing DAX metrics and dimensions
- Creating CloudWatch alarms to monitor DAX
- Production monitoring

How do I use DAX metrics?

The metrics reported by DAX provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, and not a comprehensive list.

How Can I?	Relevant Metrics
Determine if any system errors occurred	Monitor `FaultRequestCount` to determine if any requests resulted in an HTTP 500 (server error) code. This can indicate a DAX internal service error or an HTTP 500 in the underlying table's SystemErrors metric.
Determine if any user errors occurred	Monitor `ErrorRequestCount` to determine if any requests resulted in an HTTP 400 (client error) code. If you see the error count growing, you might want to investigate and make sure you are sending correct client requests.
Determine if any cache misses occurred	Monitor `ItemCacheMisses` to determine the number of times an item was not found in the cache, and `QueryCach`

How Can I?	Relevant Metrics
	`eMisses` and `ScanCacheMisses` to determine the number of times a query or scan result was not found in the cache.
Monitor cache hit rates	Use CloudWatch Metric Math to define a cache hit rate metric using math expressions. For example, for the item cache, you can use the expression m1/SUM([m1, m2])*100, where m1 is the `ItemCacheHits` metric and m2 is the `ItemCacheMisses` metric for your cluster. For the query and scan caches, you can follow the same pattern using the corresponding query and scan cache metric.

Viewing DAX metrics and dimensions

When you interact with Amazon DynamoDB, it sends metrics and dimensions to Amazon CloudWatch. You can use the following procedures to view the metrics for DynamoDB Accelerator (DAX).

To view metrics (console)

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Select the **DAX** namespace.

To view metrics (AWS CLI)

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/DAX"
```

DAX metrics and dimensions

The following sections contain the metrics and dimensions that DAX sends to CloudWatch.

DAX Metrics

The following metrics are available from DAX. DAX sends metrics to CloudWatch only when they have a non-zero value.

> **Note**
>
> CloudWatch aggregates the following DAX metrics at one-minute intervals:
>
> - CPUUtilization
> - CacheMemoryUtilization
> - NetworkBytesIn
> - NetworkBytesOut
> - BaselineNetworkBytesInUtilization
> - BaselineNetworkBytesOutUtilization
> - NetworkPacketsIn
> - NetworkPacketsOut
> - GetItemRequestCount
> - BatchGetItemRequestCount
> - BatchWriteItemRequestCount
> - DeleteItemRequestCount
> - PutItemRequestCount
> - UpdateItemRequestCount
> - TransactWriteItemsCount
> - TransactGetItemsCount
> - ItemCacheHits
> - ItemCacheMisses
> - QueryCacheHits
> - QueryCacheMisses
> - ScanCacheHits
> - ScanCacheMisses
> - TotalRequestCount
> - ErrorRequestCount

- FaultRequestCount
- FailedRequestCount
- QueryRequestCount
- ScanRequestCount
- ClientConnections
- EstimatedDbSize
- EvictedSize
- CPUCreditUsage
- CPUCreditBalance
- CPUSurplusCreditBalance
- CPUSurplusCreditsCharged

Not all statistics, such as Average or Sum, are applicable for every metric. However, all of these values are available through the DAX console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics. In the following table, each metric has a list of valid statistics that are applicable to that metric.

Metric	Description
CPUUtilization	The percentage of CPU utilization of the node or cluster. Units: Percent Valid Statistics: • Minimum • Maximum • Average
CacheMemoryUtilization	The percentage of available cache memory that is in use by the item cache and query cache on the node or cluster. Cached data starts to be evicted prior to memory utilization reaching 100% (see EvictedSize metric). If CacheMemoryUtilization reaches 100% on any node, write

Metric	Description
	requests will be throttled and you should consider switching to a cluster with a larger node type. Units: `Percent` Valid Statistics: • `Minimum` • `Maximum` • `Average`
`NetworkBytesIn`	The number of bytes received on all network interfaces by the node or cluster. Units: `Bytes` Valid Statistics: • `Minimum` • `Maximum` • `Average`
`NetworkBytesOut`	The number of bytes sent out on all network interfaces by the node or cluster. This metric identifies the volume of outgoing traffic in terms of the number of bytes on a single node or cluster. Units: `Bytes` Valid Statistics: • `Minimum` • `Maximum` • `Average`

Metric	Description
BaselineNetworkBytesInUtilization	The percentage of the consumed baseline network bandwidth at a given time for ingress traffic. For reference, 50% means half of the available network bandwidth for ingress traffic is being used. Units: Percent Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
BaselineNetworkBytesOutUtilization	The percentage of the consumed baseline network bandwidth at a given time for egress traffic. For reference, 50% means half of the available network bandwidth for egress traffic is being used. Units: Percent Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
NetworkPacketsIn	The number of packets received on all network interfaces by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average
NetworkPacketsOut	The number of packets sent out on all network interfaces by the node or cluster. This metric identifies the volume of outgoing traffic in terms of the number of packets on a single node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average
GetItemRequestCount	The number of GetItem requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
BatchGetItemRequestCount	The number of BatchGetItem requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
BatchWriteItemRequestCount	The number of BatchWriteItem requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
DeleteItemRequestCount	The number of DeleteItem requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
PutItemRequestCount	The number of PutItem requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
UpdateItemRequestCount	The number of UpdateItem requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
TransactWriteItemsCount	The number of TransactWriteItems requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
TransactGetItemsCount	The number of TransactGetItems requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
ItemCacheHits	The number of times an item was returned from the cache by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
ItemCacheMisses	The number of times an item was not in the node or cluster cache, and had to be retrieved from DynamoDB. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
QueryCacheHits	The number of times a query result was returned from the node or cluster cache. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
QueryCacheMisses	The number of times a query result was not in the node or cluster cache, and had to be retrieved from DynamoDB. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
ScanCacheHits	The number of times a scan result was returned from the node or cluster cache. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
ScanCacheMisses	The number of times a scan result was not in the node or cluster cache, and had to be retrieved from DynamoDB. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
TotalRequestCount	Total number of requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
ErrorRequestCount	Total number of requests that resulted in a user error reported by the node or cluster. Requests that were throttled by the node or cluster are included. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
ThrottledRequestCount	Total number of requests throttled by the node or cluster. Requests that were throttled by DynamoDB are not included, and can be monitored using DynamoDB Metrics. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
FaultRequestCount	Total number of requests that resulted in an internal error reported by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
FailedRequestCount	Total number of requests that resulted in an error reported by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
QueryRequestCount	The number of query requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
ScanRequestCount	The number of scan requests handled by the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
ClientConnections	The number of simultaneous connections made by clients to the node or cluster. Units: Count Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum
EstimatedDbSize	An approximation of the amount of data cached in the item cache and the query cache by the node or cluster. Units: Bytes Valid Statistics: • Minimum • Maximum • Average

Metric	Description
EvictedSize	The amount of data that was evicted by the node or cluster to make room for newly requested data. If the miss rate goes up, and you see this metric also growing, it probably means that your working set has increased. You should consider switching to a cluster with a larger node type. Units: Bytes Valid Statistics: • Minimum • Maximum • Average • Sum
CPUCreditUsage	The number of CPU credits spent by the node for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes). CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average. Units: Credits (vCPU-minutes) Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
CPUCreditBalance	The number of earned CPU credits that a node has accrued since it was launched or started. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the DAX node size. After the limit is reached, any new credits that are earned are discarded. The credits in the CPUCreditBalance are available for the node to spend to burst beyond its baseline CPU utilization. Units: Credits (vCPU-minutes) Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
CPUSurplusCreditBalance	The number of surplus credits that have been spent by a DAX node when its CPUCreditBalance value is zero. The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the node can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. Units: Credits (vCPU-minutes) Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Metric	Description
CPUSurplusCreditsCharged	The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge. Spent surplus credits are charged when the spent surplus credits exceed the maximum number of credits that the node can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour or when the node is terminated. Units: Credits (vCPU-minutes) Valid Statistics: • Minimum • Maximum • Average • SampleCount • Sum

Note

The CPUCreditUsage, CPUCreditBalance, CPUSurplusCreditBalance, and CPUSurplusCreditsCharged metrics are available only for T3 nodes.

Dimensions for DAX Metrics

The metrics for DAX are qualified by the values for the account, cluster ID, or cluster ID and node ID combination. You can use the CloudWatch console to retrieve DAX data along any of the dimensions in the following table.

Dimension	Description
`Account`	Provides aggregated statistics across all nodes in an account.
`ClusterId`	Limits the data to a cluster.
`ClusterId, NodeId`	Limits the data to a node within a cluster.

Creating CloudWatch alarms to monitor DAX

You can create an Amazon CloudWatch alarm that sends an Amazon Simple Notification Service (Amazon SNS) message when the alarm changes state. An alarm watches a single metric over a time period that you specify. It performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification that is sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods.

How can I be notified of query cache misses?

1. Create an Amazon SNS topic, `arn:aws:sns:us-west-2:522194210714:QueryMissAlarm`.

   For more information, see Set Up Amazon Simple Notification Service in the *Amazon CloudWatch User Guide*.

2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
    --alarm-name QueryCacheMissesAlarm  \
    --alarm-description "Alarm over query cache misses" \
    --namespace AWS/DAX \
```

```
    --metric-name QueryCacheMisses  \
    --dimensions Name=ClusterID,Value=myCluster \
    --statistic Sum \
    --threshold 8 \
    --comparison-operator GreaterThanOrEqualToThreshold \
    --period 60 \
    --evaluation-periods 1 \
    --alarm-actions arn:aws:sns:us-west-2:522194210714:QueryMissAlarm
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name QueryCacheMissesAlarm --state-reason
 "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name QueryCacheMissesAlarm --state-reason
 "initializing" --state-value ALARM
```

Note

You can increase or decrease the threshold to one that makes sense for your application. You can also use CloudWatch Metric Math to define a cache miss rate metric and set an alarm over that metric.

How can I be notified if requests cause an internal error in the cluster?

1. Create an Amazon SNS topic, `arn:aws:sns:us-west-2:123456789012:notify-on-system-errors`.

   For more information, see Set Up Amazon Simple Notification Service in the *Amazon CloudWatch User Guide*.

2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
    --alarm-name FaultRequestCountAlarm \
    --alarm-description "Alarm when a request causes an internal error" \
    --namespace AWS/DAX \
    --metric-name FaultRequestCount \
    --dimensions Name=ClusterID,Value=myCluster \
```

```
    --statistic Sum \
    --threshold 0 \
    --comparison-operator GreaterThanThreshold \
    --period 60 \
    --unit Count \
    --evaluation-periods 1 \
    --alarm-actions arn:aws:sns:us-east-1:123456789012:notify-on-system-errors
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name FaultRequestCountAlarm --state-reason
 "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name FaultRequestCountAlarm --state-reason
 "initializing" --state-value ALARM
```

Production monitoring

You should establish a baseline for normal DAX performance in your environment, by measuring performance at various times and under different load conditions. As you monitor DAX, you should consider storing historical monitoring data. This stored data gives you a baseline from which to compare current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

To establish a baseline, you should, at minimum, monitor the following items both during load testing and in production.

- CPU utilization and throttled requests, so that you can determine whether you might need to use a larger node type in your cluster. The CPU utilization of your cluster is available through the `CPUUtilization` CloudWatch metric. The average stat on this metric provides an average CPU utilization view across all the nodes in your cluster. For cluster scaling decisions, we recommend that you use the maximum stat which is the maximum utilization across all the nodes.

> **Note**
>
> AWS has improved the `CPUUtilization` metric's granularity. You might observe changes to the metric starting from 2024-05-17 to 2024-06-22.

- Operation latency (as measure on the client side) should remain consistent within your application's latency requirements.
- Error rates should remain low, as seen from the `ErrorRequestCount`, `FaultRequestCount`, and `FailedRequestCount` CloudWatch metrics.
- Network bytes consumption, so that you can determine if you should use more nodes or a larger node type in your cluster. To monitor consumption, you can set alerts on `BaselineNetworkBytesInUtilization` and `BaselineNetworkBytesOutUtilization` metrics available in CloudWatch, which indicates percentage consumption of available network bandwidth for your instance type, for ingress and egress traffic respectively.
- Cache memory utilization and evicted size, so that you can determine whether the cluster's node type has sufficient memory to hold your working set, and if not, switch to a larger node type.

  > **Note**
  >
  > In case of a large number of cache misses and writes, cache memory utilization can increase up to 100% and might cause availability downtime.

- Client connections, so that you can monitor for any unexplained spikes in connections to the cluster.

Logging DAX operations using AWS CloudTrail

Amazon DynamoDB Accelerator (DAX) is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in DAX.

To learn more about DAX and CloudTrail, see the DynamoDB Accelerator (DAX) section in Logging DynamoDB operations by using AWS CloudTrail.

DAX T3/T2 burstable instances

DAX allows you to choose between fixed performance instances (such as R4, R5, and R7) and burstable performance instances (such as T2 and T3). Burstable performance instances provide a baseline level of CPU performance with the ability to burst above the baseline when needed.

Baseline performance and the ability to burst above it are governed by CPU credits. Burstable performance instances accumulate CPU credits continuously, at a rate determined by the instance size, when the workload is below the baseline threshold. These credits might then be consumed

when the workload increases. A CPU credit provides the performance of a full CPU core for one minute.

Many workloads don't need consistently high levels of CPU, but benefit significantly from having full access to very fast CPUs when they need them. Burstable performance instances are engineered specifically for these use cases. If you need consistently high CPU performance for your database, we recommend you use fixed performance instances.

DAX T2 instance family

DAX T2 instances are burstable general-purpose performance instances that provide a baseline level of CPU performance with the ability to burst above the baseline. T2 instances are a good choice for test and development workloads which need price predictability. DAX T2 instances are configured for standard mode, which means that if the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level. For more information on standard mode, refer to Standard mode for burstable performance instances in the Amazon EC2 User Guide.

DAX T3 instance family

DAX T3 instances are the next generation burstable general-purpose instance type, providing a baseline level of CPU performance with the ability to burst CPU usage at any time for as long as required. T3 instances offer a balance of compute, memory, and network resources and are ideal for workloads with moderate CPU usage that experience temporary spikes in use. DAX T3 instances are configured for unlimited mode, which means they can burst beyond the baseline over a 24-hour window for an additional charge. For more information on unlimited mode, refer to Unlimited mode for burstable performance instances in the Amazon EC2 User Guide.

DAX T3 instances can sustain high CPU performance for as long as a workload requires it. For most general-purpose workloads, T3 instances will provide ample performance without any additional charges. The hourly T3 instance price automatically covers all interim spikes in usage when the average CPU utilization of a T3 instance is at or less than the baseline over a 24-hour window.

For example, a `dax.t3.small` instance receives credits continuously at a rate of 24 CPU credits per hour. This capability provides baseline performance equivalent to 20% of a CPU core (20% × 60 minutes = 12 minutes). If the instance does not use the credits it receives, they are stored in its CPU credit balance up to a maximum of 576 CPU credits. When the `t3.small` instance needs to burst to more than 20% of a core, it draws from its CPU credit balance to handle this surge automatically.

While DAX T2 instances are restricted to baseline performance after the CPU credit balance is drawn down to zero, DAX T3 instances can burst above the baseline even when their CPU credit balance is zero. For the vast majority of workloads, where the average CPU utilization is at or below the baseline performance, the basic hourly price for `t3.small` covers all CPU bursts. If the instance happens to run at an average 25% CPU utilization (5% above baseline) over a period of 24 hours after its CPU credit balance is drawn to zero, it will be charged an additional 11.52 cents (9.6 cents/vCPU-hour × 1 vCPU × 5% × 24 hours). See Amazon DynamoDB Pricing for pricing details.

DAX access control

DynamoDB Accelerator (DAX) is designed to work together with DynamoDB, to seamlessly add a caching layer to your applications. However, DAX and DynamoDB have separate access control mechanisms. Both services use AWS Identity and Access Management (IAM) to implement their respective security policies, but the security models for DAX and DynamoDB are different.

We highly recommend that you understand both security models, so that you can implement proper security measures for your applications that use DAX.

This section describes the access control mechanisms provided by DAX and provides sample IAM policies that you can tailor to your needs.

> **Protect sensitive data in cluster names**
>
> When you create a DAX cluster, do not include sensitive identifying information, such as your customers' account numbers, in the cluster name. Cluster names can be visible outside your account. When you enable encryption in transit, DAX uses AWS Certificate Manager (ACM) to provision a Transport Layer Security (TLS) certificate for the cluster endpoint, and that certificate includes your cluster name.
> ACM automatically records every public certificate that it issues in public Certificate Transparency (CT) logs, and browser policy requirements prevent you from opting out. As a result, public CT logs contain the names of TLS-enabled DAX clusters after ACM issues or renews the certificate. For general guidance on resource naming, see Data protection in DynamoDB. For more information about CT logging, see Certificate transparency logging in the *AWS Certificate Manager User Guide*.

With DynamoDB, you can create IAM policies that limit the actions a user can perform on individual DynamoDB resources. For example, you can create a user role that only allows the user to perform

read-only actions on a particular DynamoDB table. (For more information, see Identity and Access Management for Amazon DynamoDB.) By comparison, the DAX security model focuses on cluster security, and the ability of the cluster to perform DynamoDB API actions on your behalf.

> **Warning**
>
> If you are currently using IAM roles and policies to restrict access to DynamoDB tables data, then the use of DAX can **subvert** those policies. For example, a user could have access to a DynamoDB table through DAX but not have explicit access to the same table accessing DynamoDB directly. For more information, see Identity and Access Management for Amazon DynamoDB.
>
> DAX does not enforce user-level separation on data in DynamoDB. Instead, users inherit the permissions of the DAX cluster's IAM policy when they access that cluster. Thus, when accessing DynamoDB tables through DAX, the only access controls that are in effect are the permissions in the DAX cluster's IAM policy. No other permissions are recognized.
>
> If you require isolation, we recommend that you create additional DAX clusters and scope the IAM policy for each cluster accordingly. For example, you could create multiple DAX clusters and allow each cluster to access only a single table.

IAM service role for DAX

When you create a DAX cluster, you must associate the cluster with an IAM role. This is known as the *service role* for the cluster.

Suppose that you wanted to create a new DAX cluster named *DAXCluster01*. You could create a service role named *DAXServiceRole*, and associate the role with *DAXCluster01*. The policy for *DAXServiceRole* would define the DynamoDB actions that *DAXCluster01* could perform, on behalf of the users who interact with *DAXCluster01*.

When you create a service role, you must specify a trust relationship between *DAXServiceRole* and the DAX service itself. A trust relationship determines which entities can assume a role and make use of its permissions. The following is an example trust relationship document for *DAXServiceRole*:

JSON

```
{
    "Version":"2012-10-17",
```

```
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "dax.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

This trust relationship allows a DAX cluster to assume *DAXServiceRole* and perform DynamoDB API calls on your behalf.

The DynamoDB API actions that are allowed are described in an IAM policy document, which you attach to *DAXServiceRole*. The following is an example policy document.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DaxAccessPolicy",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeTable",
                "dynamodb:PutItem",
                "dynamodb:GetItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:BatchGetItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
            ]
        }
```

```
    ]
}
```

This policy allows DAX to perform necessary DynamoDB API actions on a DynamoDB table. The `dynamodb:DescribeTable` action is required for DAX to maintain metadata about the table, and the others are read and write actions performed on items in the table. The table, named `Books`, is in the us-west-2 Region and is owned by AWS account ID `123456789012`.

> **Note**
>
> DAX supports mechanisms to prevent the confused deputy problem during cross-Service access. For more information, see The confused deputy problem in the *IAM User Guide*.

IAM policy to allow DAX cluster access

After you create a DAX cluster, you need to grant permissions to a user so that the user can access the DAX cluster.

For example, suppose that you want to grant access to *DAXCluster01* to a user named Alice. You would first create an IAM policy (*AliceAccessPolicy*) that defines the DAX clusters and DAX API actions that the recipient can access. You would then confer access by attaching this policy to user Alice.

The following policy document gives the recipient full access on *DAXCluster01*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "dax:*"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
            ]
```

```
        }
    ]
}
```

The policy document allows access to the DAX cluster, but it does not grant any DynamoDB permissions. (The DynamoDB permissions are conferred by the DAX service role.)

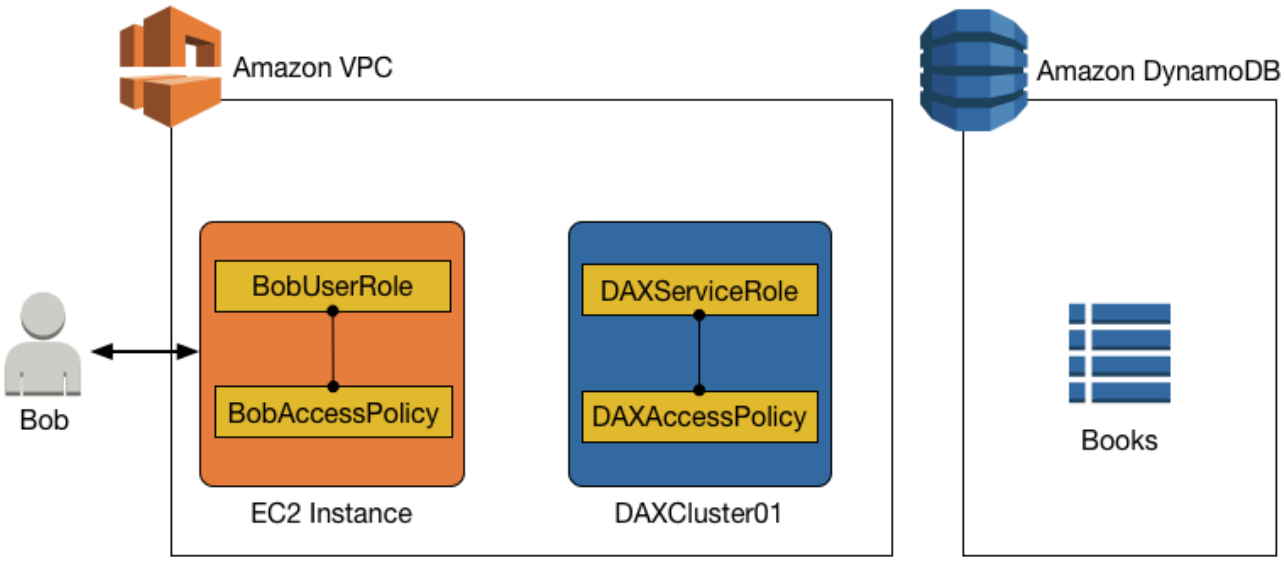
For user Alice, you would first create `AliceAccessPolicy` with the policy document shown previously. You would then attach the policy to Alice.

> **Note**
>
> Instead of attaching the policy to a user, you could attach it to an IAM role. That way, all of the users who assume that role would have the permissions that you defined in the policy.

The user policy, together with the DAX service role, determine the DynamoDB resources and API actions that the recipient can access through DAX.

Case study: Accessing DynamoDB and DAX

The following scenario can help further your understanding of IAM policies for use with DAX. (This scenario is referred to throughout the rest of this section.) The following diagram shows a high-level overview of the scenario.

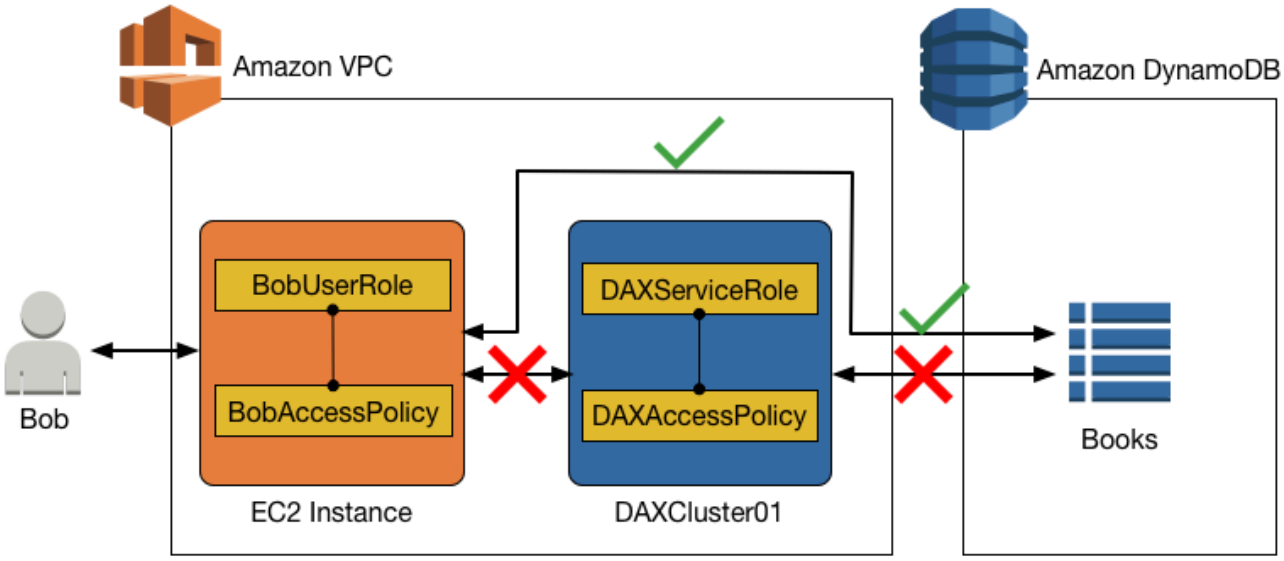


In this scenario, there are the following entities:

- A user (Bob).
- An IAM role (`BobUserRole`). Bob assumes this role at runtime.
- An IAM policy (`BobAccessPolicy`). This policy is attached to `BobUserRole`. `BobAccessPolicy` defines the DynamoDB and DAX resources that `BobUserRole` is allowed to access.
- A DAX cluster (`DAXCluster01`).
- An IAM service role (`DAXServiceRole`). This role allows `DAXCluster01` to access DynamoDB.
- An IAM policy (`DAXAccessPolicy`). This policy is attached to `DAXServiceRole`. `DAXAccessPolicy` defines the DynamoDB APIs and resources that `DAXCluster01` is allowed to access.
- A DynamoDB table (`Books`).

The combination of policy statements in `BobAccessPolicy` and `DAXAccessPolicy` determine what Bob can do with the `Books` table. For example, Bob might be able to access `Books` directly (using the DynamoDB endpoint), indirectly (using the DAX cluster), or both. Bob might also be able to read data from `Books`, write data to `Books`, or both.

Access to DynamoDB, but no access with DAX



It is possible to allow direct access to a DynamoDB table, while preventing indirect access using a DAX cluster. For direct access to DynamoDB, the permissions for `BobUserRole` are determined by `BobAccessPolicy` (which is attached to the role).

Read-only access to DynamoDB (only)

Bob can access DynamoDB with `BobUserRole`. The IAM policy attached to this role (`BobAccessPolicy`) determines the DynamoDB tables that `BobUserRole` can access, and what APIs that `BobUserRole` can invoke.

Consider the following policy document for `BobAccessPolicy`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
```

```
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

When this document is attached to `BobAccessPolicy`, it allows `BobUserRole` to access the DynamoDB endpoint and perform read-only operations on the `Books` table.

DAX does not appear in this policy, so access through DAX is denied.

Read/write access to DynamoDB (only)

If `BobUserRole` requires read/write access to DynamoDB, the following policy would work.

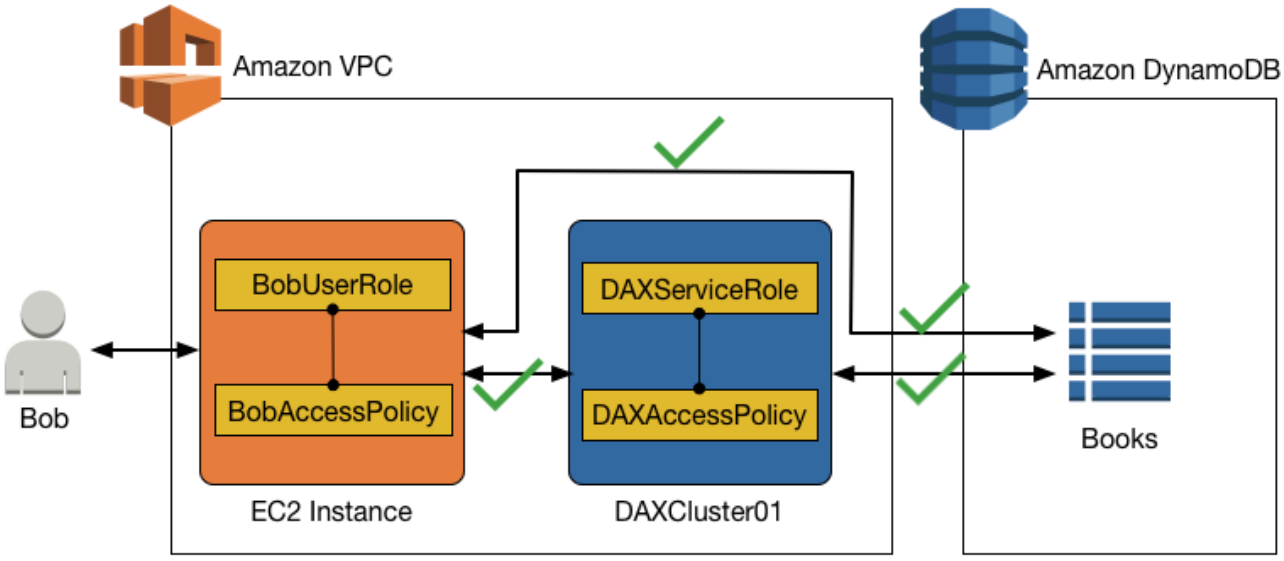
JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
```

```
}
```

Again, DAX does not appear in this policy, so access through DAX is denied.

Access to DynamoDB and to DAX



To allow access to a DAX cluster, you must include DAX-specific actions in an IAM policy.

The following DAX-specific actions correspond to their similarly named counterparts in the DynamoDB API:

- `dax:GetItem`
- `dax:BatchGetItem`
- `dax:Query`
- `dax:Scan`
- `dax:PutItem`
- `dax:UpdateItem`
- `dax:DeleteItem`
- `dax:BatchWriteItem`
- `dax:ConditionCheckItem`

The same is true for the `dax:EnclosingOperation` condition key.

Read-only access to DynamoDB and read-only access to DAX

Suppose that Bob requires read-only access to the `Books` table, from DynamoDB and from DAX. The following policy (attached to `BobUserRole`) confers this access.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DAXAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan"
            ],
            "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
        },
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

The policy has a statement for DAX access (`DAXAccessStmt`) and another statement for DynamoDBaccess (`DynamoDBAccessStmt`). These statements allow Bob to send `GetItem`, `BatchGetItem`, `Query`, and `Scan` requests to `DAXCluster01`.

However, the service role for `DAXCluster01` would also require read-only access to the `Books` table in DynamoDB. The following IAM policy, attached to `DAXServiceRole`, would fulfill this requirement.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

Read/write access to DynamoDB and read-only with DAX

For a given user role, you can provide read/write access to a DynamoDB table, while also allowing read-only access through DAX.

For Bob, the IAM policy for `BobUserRole` would need to allow DynamoDB read and write actions on the `Books` table, while also supporting read-only actions through `DAXCluster01`.

The following example policy document for `BobUserRole` confers this access.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DAXAccessStmt",
```

```
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan"
            ],
            "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
        },
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:DescribeTable",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

In addition, `DAXServiceRole` would require an IAM policy that allows `DAXCluster01` to perform read-only actions on the `Books` table.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
```

```
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:DescribeTable"
            ],
             "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

Read/write access to DynamoDB and read/write access to DAX

Now suppose that Bob required read/write access to the `Books` table, directly from DynamoDB or indirectly from `DAXCluster01`. The following policy document, attached to `BobAccessPolicy`, confers this access.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DAXAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan",
                "dax:PutItem",
                "dax:UpdateItem",
                "dax:DeleteItem",
                "dax:BatchWriteItem",
                "dax:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
        },
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
```

```
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:DescribeTable",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

In addition, `DAXServiceRole` would require an IAM policy that allows `DAXCluster01` to perform read/write actions on the `Books` table.

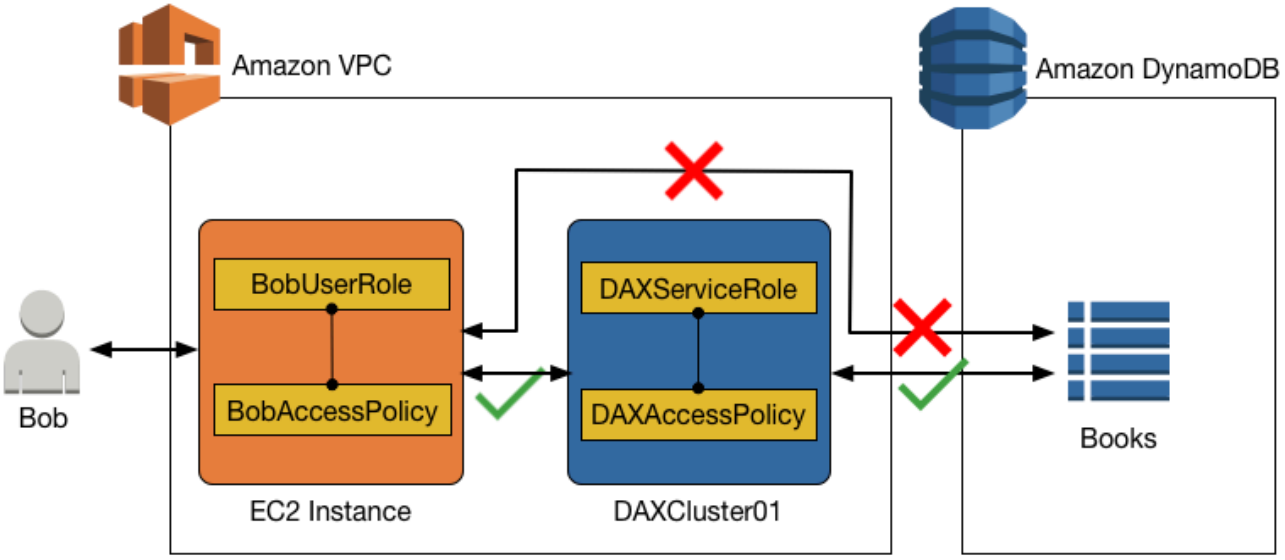
JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:DescribeTable"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
```

```
    ]
}
```

Access to DynamoDB through DAX, but no direct access to DynamoDB

In this scenario, Bob can access the `Books` table through DAX, but he does not have direct access to the `Books` table in DynamoDB. Thus, when Bob gains access to DAX, he also gains access to a DynamoDB table that he otherwise might not be able to access. When you configure an IAM policy for the DAX service role, remember that any user that is given access to the DAX cluster through the user access policy gains access to the tables specified in that policy. In this case, `BobAccessPolicy` gains access to the tables specified in `DAXAccessPolicy`.



If you are currently using IAM roles and policies to restrict access to DynamoDB tables and data, using DAX can subvert those policies. In the following policy, Bob has access to a DynamoDB table through DAX but does not have explicit direct access to the same table in DynamoDB.

The following policy document (`BobAccessPolicy`), attached to `BobUserRole`, would confer this access.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DAXAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan",
                "dax:PutItem",
                "dax:UpdateItem",
                "dax:DeleteItem",
                "dax:BatchWriteItem",
                "dax:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
        }
    ]
}
```

In this access policy, there are no permissions to access DynamoDB directly.

Together with `BobAccessPolicy`, the following `DAXAccessPolicy` gives `BobUserRole` access to the DynamoDB table `Books` even though `BobUserRole` cannot directly access the `Books` table.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
```

```
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:DescribeTable",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

As this example shows, when you configure access control for the user access policy and the DAX cluster access policy, you must fully understand the end-to-end access to make sure that the principle of least privilege is observed. Also make sure that giving a user access to a DAX cluster does not subvert previously established access control policies.

DAX encryption at rest

Amazon DynamoDB Accelerator (DAX) encryption at rest provides an additional layer of data protection by helping secure your data from unauthorized access to the underlying storage. Organizational policies, industry or government regulations, and compliance requirements might require the use of encryption at rest to protect your data. You can use encryption to increase the data security of your applications that are deployed in the cloud.

With encryption at rest, the data persisted by DAX on disk is encrypted using 256-bit Advanced Encryption Standard, also known as AES-256 encryption. DAX writes data to disk as part of propagating changes from the primary node to read replicas.

DAX encryption at rest automatically integrates with AWS Key Management Service (AWS KMS) for managing the single service default key that is used to encrypt your clusters. If a service default key doesn't exist when you create your encrypted DAX cluster, AWS KMS automatically creates a new AWS managed key for you. This key is used with encrypted clusters that are created in the future. AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud.

After your data is encrypted, DAX handles the decryption of your data transparently with minimal impact on performance. You don't need to modify your applications to use encryption.

> **Note**
>
> DAX does not call AWS KMS for every single DAX operation. DAX only uses the key at the cluster launch. Even if access is revoked, DAX can still access the data until the cluster is shut down. Customer-specified AWS KMS keys are not supported.

DAX encryption at rest is available for the following cluster node types.

Family	Node type
Memory-optimized (R4, R5, and R7)	dax.r4.large
	dax.r4.xlarge
	dax.r4.2xlarge
	dax.r4.4xlarge
	dax.r4.8xlarge
	dax.r4.16xlarge
	dax.r5.large
	dax.r5.xlarge
	dax.r5.2xlarge
	dax.r5.4xlarge
	dax.r5.8xlarge
	dax.r5.12xlarge
	dax.r5.16xlarge
	dax.r5.24xlarge

Family	Node type
	dax.r7i.large dax.r7i.xlarge dax.r7i.2xlarge dax.r7i.4xlarge dax.r7i.8xlarge dax.r7i.12xlarge dax.r7i.16xlarge dax.r7i.24xlarge
General purpose (T2)	dax.t2.small dax.t2.medium
General purpose (T3)	dax.t3.small dax.t3.medium

Important

DAX encryption at rest is not supported for `dax.r3.*` node types.

You cannot enable or disable encryption at rest after a cluster has been created. You must re-create the cluster to enable encryption at rest if it was not enabled at creation.

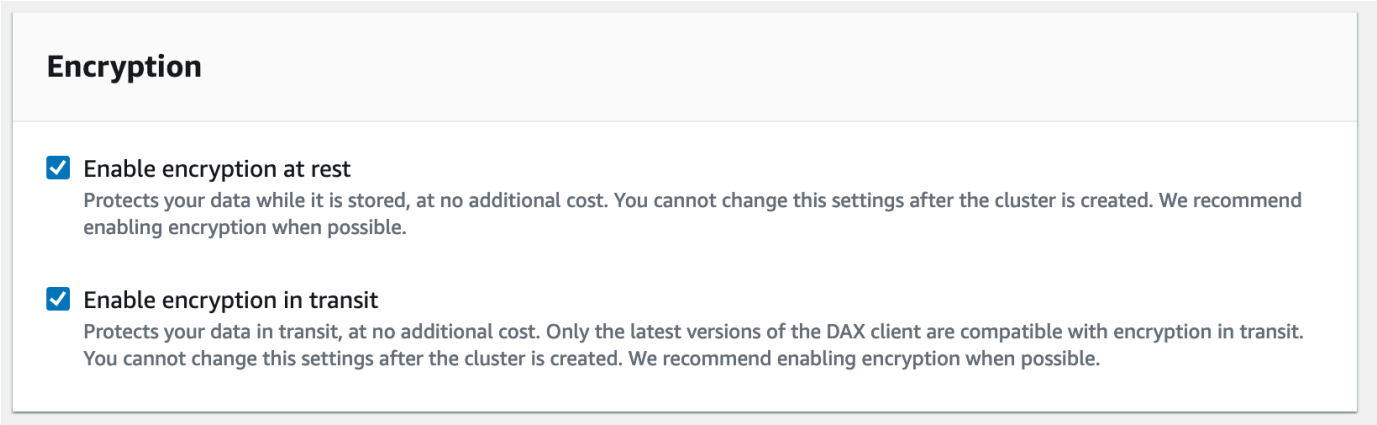
DAX encryption at rest is offered at no additional cost (AWS KMS encryption key usage charges apply). For information about pricing, see Amazon DynamoDB pricing.

Enabling encryption at rest using the AWS Management Console

Follow these steps to enable DAX encryption at rest on a table using the console.

To enable DAX encryption at rest

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, under **DAX**, choose **Clusters**.
3. Choose **Create cluster**.
4. For **Cluster name**, enter a short name for your cluster. Choose the **node type** for all of the nodes in the cluster, and for the cluster size, use **3** nodes.
5. In **Encryption**, make sure that **Enable encryption** is selected.



6. After choosing the IAM role, subnet group, security groups, and cluster settings, choose **Launch cluster**.

To confirm that the cluster is encrypted, check the cluster details under the **Clusters** pane. Encryption should be **ENABLED**.

DAX encryption in transit

Amazon DynamoDB Accelerator (DAX) supports encryption in transit of data between your application and your DAX cluster, enabling you to use DAX in applications with stringent encryption requirements.

Regardless of whether or not you choose encryption in transit, traffic between your application and your DAX cluster remains in your Amazon VPC. This traffic is routed to Elastic Network Interfaces with private IPs in your VPC that are attached to the nodes of your cluster. With your VPC as the trust boundary, you have significant control over the security of your data through the use of standard tools like security groups, subnet segmentation with Network ACLs, and VPC flow

tracing. DAX encryption in transit adds to this baseline level of confidentiality, ensuring that all requests and responses between the application and the cluster are encrypted by transport level security (TLS), and connections to the cluster can be authenticated by verification of a cluster x509 certificate. Data written to disk by DAX can also be encrypted if you choose encryption at rest when creating your DAX cluster.

Using encryption in transit with DAX is easy. Simply select this option when creating a new cluster, and use a recent version of any of the DAX clients in your application. Clusters that use encryption in transit do not support unencrypted traffic, so there is no chance to misconfigure your application and bypass encryption. The DAX client will use the cluster's x509 certificate to authenticate the identity of the cluster when it establishes connections, ensuring that your DAX requests go where intended. All methods of creating DAX clusters support encryption in transit: the AWS Management Console, AWS CLI, all SDKs, and CloudFormation.

Encryption in transit cannot be enabled on an existing DAX cluster. To use encryption in transit in an existing DAX application, create a new cluster with encryption in transit enabled, shift your application's traffic to it, then delete the old cluster.

Using service-linked IAM roles for DAX

Amazon DynamoDB Accelerator (DAX) uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to DAX. Service-linked roles are predefined by DAX and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up DAX easier because you don’t have to manually add the necessary permissions. DAX defines the permissions of its service-linked roles, and unless defined otherwise, only DAX can assume its roles. The defined permissions include the trust policy and the permissions policy. That permissions policy can't be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your DAX resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM in the *IAM User Guide*. Look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** link to view the service-linked role documentation for that service.

Topics

- Service-linked role permissions for DAX
- Creating a service-linked role for DAX
- Editing a service-linked role for DAX
- Deleting a service-linked role for DAX

Service-linked role permissions for DAX

DAX uses the service-linked role named `AWSServiceRoleForDAX`. This role allows DAX to call services on behalf of your DAX cluster.

> **Important**
>
> The `AWSServiceRoleForDAX` service-linked role makes it easier for you to set up and maintain a DAX cluster. However, you must still grant each cluster access to DynamoDB before you can use it. For more information, see DAX access control.

The `AWSServiceRoleForDAX` service-linked role trusts the following services to assume the role:

- `dax.amazonaws.com`

The role permissions policy allows DAX to complete the following actions on the specified resources:

- Actions on `ec2`:
  - `AuthorizeSecurityGroupIngress`
  - `CreateNetworkInterface`
  - `CreateSecurityGroup`
  - `DeleteNetworkInterface`
  - `DeleteSecurityGroup`
  - `DescribeAvailabilityZones`
  - `DescribeNetworkInterfaces`
  - `DescribeSecurityGroups`
  - `DescribeSubnets`

- `DescribeVpcs`
- `ModifyNetworkInterfaceAttribute`
- `RevokeSecurityGroupIngress`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the *IAM User Guide*.

To allow an IAM entity to create AWSServiceRoleForDAX service-linked roles

Add the following policy statement to the permissions for that IAM entity.

```
{
    "Effect": "Allow",
    "Action": [
        "iam:CreateServiceLinkedRole"
    ],
    "Resource": "*",
    "Condition": {"StringLike": {"iam:AWSServiceName": "dax.amazonaws.com"}}
}
```

Creating a service-linked role for DAX

You don't need to manually create a service-linked role. When you create a cluster, DAX creates the service-linked role for you.

> **Important**
>
> If you were using the DAX service before February 28, 2018, when it began supporting service-linked roles, DAX created the `AWSServiceRoleForDAX` role in your account. For more information, see A New Role Appeared in My AWS Account in the *IAM User Guide*.

If you delete this service-linked role and then need to create it again, you can use the same process to re-create the role in your account. When you create an instance or a cluster, DAX creates the service-linked role for you again.

Editing a service-linked role for DAX

DAX does not allow you to edit the `AWSServiceRoleForDAX` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the *IAM User Guide*.

Deleting a service-linked role for DAX

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DAX clusters before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the **AWSServiceRoleForDAX** role.
3. On the **Summary** page for the selected role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether DAX is using the `AWSServiceRoleForDAX` role, you can try to delete the role. If the service is using the role, the deletion fails, and you can view the Regions where the role is being used. If the role is being used, you must delete your DAX clusters before you can delete the role. You can't revoke the session for a service-linked role.

If you want to remove the `AWSServiceRoleForDAX` role, you must first delete all of your DAX clusters.

Deleting all of your DAX clusters

Use one of these procedures to delete each of your DAX clusters.

To delete a DAX cluster (console)

1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane, under **DAX**, choose **Clusters**.
3. Choose **Actions**, and then choose **Delete**.
4. In the **Delete cluster confirmation** box, choose **Delete**.

To delete a DAX cluster (AWS CLI)

See delete-cluster in the *AWS CLI Command Reference*.

To delete a DAX cluster (API)

See DeleteCluster in the *Amazon DynamoDB API Reference*.

Deleting the service-linked role

To manually delete the service-linked role using IAM

Use the IAM console, the IAM CLI, or the IAM API to delete the `AWSServiceRoleForDAX` service-linked role. For more information, see Deleting a Service-Linked Role in the *IAM User Guide*.

Accessing DAX across AWS accounts

Imagine that you have a DynamoDB Accelerator (DAX) cluster running in one AWS account (account A), and the DAX cluster needs to be accessible from an Amazon Elastic Compute Cloud (Amazon EC2) instance in another AWS account (account B). In this tutorial, you accomplish this by launching an EC2 instance in account B with an IAM role from account B. You then use temporary security credentials from the EC2 instance to assume an IAM role from account A. Finally, you use the temporary security credentials from assuming the IAM role in account A to make application calls over an Amazon VPC peering connection to the DAX cluster in account A. In order to perform these tasks you will need administrative access in both AWS accounts.

> **Important**
>
> It is not possible to have a DAX cluster access a DynamoDB table from a different account.

Topics

- Set up IAM
- Set up a VPC
- Modify the DAX client to allow cross-account access

Set up IAM

1. Create a text file named `AssumeDaxRoleTrust.json` with the following content, which allows Amazon EC2 to work on your behalf.

   JSON

   ```
   {
       "Version":"2012-10-17",
       "Statement": [
           {
               "Effect": "Allow",
               "Principal": {
                   "Service": "ec2.amazonaws.com"
               },
               "Action": "sts:AssumeRole"
           }
       ]
   }
   ```

2. In account B, create a role that Amazon EC2 can use when launching instances.

   ```
   aws iam create-role \
       --role-name AssumeDaxRole \
       --assume-role-policy-document file://AssumeDaxRoleTrust.json
   ```

3. Create a text file named `AssumeDaxRolePolicy.json` with the following content, which allows code running on the EC2 instance in account B to assume an IAM role in account A. Replace *accountA* with the actual ID of account A.

   JSON

   ```
   {
       "Version":"2012-10-17",
       "Statement": [
           {
               "Effect": "Allow",
               "Action": "sts:AssumeRole",
               "Resource": "arn:aws:iam::111122223333:role/DaxCrossAccountRole"
           }
       ]
   }
   ```

4. Add that policy to the role you just created.

   ```
   aws iam put-role-policy \
       --role-name AssumeDaxRole \
       --policy-name AssumeDaxRolePolicy \
       --policy-document file://AssumeDaxRolePolicy.json
   ```

5. Create an instance profile to allow instances to use the role.

   ```
   aws iam create-instance-profile \
       --instance-profile-name AssumeDaxInstanceProfile
   ```

6. Associate the role with the instance profile.

   ```
   aws iam add-role-to-instance-profile \
       --instance-profile-name AssumeDaxInstanceProfile \
       --role-name AssumeDaxRole
   ```

7. Create a text file named `DaxCrossAccountRoleTrust.json` with the following content, which allows account B to assume an account A role. Replace *accountB* with the actual ID of account B.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/AssumeDaxRole"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

8. In account A, create the role that account B can assume.

```
aws iam create-role \
    --role-name DaxCrossAccountRole \
    --assume-role-policy-document file://DaxCrossAccountRoleTrust.json
```

9. Create a text file named `DaxCrossAccountPolicy.json` that allows access to the DAX cluster. Replace *dax-cluster-arn* with the correct Amazon Resource Name (ARN) of your DAX cluster.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan",
                "dax:PutItem",
                "dax:UpdateItem",
                "dax:DeleteItem",
```

```
                "dax:BatchWriteItem",
                "dax:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dax:us-east-1:111122223333:cache/dax-
cluster-name"
        }
    ]
}
```

10. In account A, add the policy to the role.

```
aws iam put-role-policy \
    --role-name DaxCrossAccountRole \
    --policy-name DaxCrossAccountPolicy \
    --policy-document file://DaxCrossAccountPolicy.json
```

Set up a VPC

1. Find the subnet group of account A's DAX cluster. Replace *cluster-name* with the name of the DAX cluster that account B must access.

```
aws dax describe-clusters \
    --cluster-name cluster-name
    --query 'Clusters[0].SubnetGroup'
```

2. Using that *subnet-group*, find the cluster's VPC.

```
aws dax describe-subnet-groups \
    --subnet-group-name subnet-group \
    --query 'SubnetGroups[0].VpcId'
```

3. Using that *vpc-id*, find the VPC's CIDR.

```
aws ec2 describe-vpcs \
    --vpc vpc-id \
    --query 'Vpcs[0].CidrBlock'
```

4. From account B, create a VPC using a different, non-overlapping CIDR than the one found in the previous step. Then, create at least one subnet. You can use either the VPC creation wizard in the AWS Management Console or the AWS CLI.

5. From account B, request a peering connection to the account A VPC as described in Creating and accepting a VPC peering connection. From account A, accept the connection.
6. From account B, find the new VPC's routing table. Replace *vpc-id* with the ID of the VPC you created in account B.

```
aws ec2 describe-route-tables \
    --filters 'Name=vpc-id,Values=vpc-id' \
    --query 'RouteTables[0].RouteTableId'
```

7. Add a route to send traffic destined for account A's CIDR to the VPC peering connection. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
aws ec2 create-route \
    --route-table-id accountB-route-table-id \
    --destination-cidr accountA-vpc-cidr \
    --vpc-peering-connection-id peering-connection-id
```

8. From account A, find the DAX cluster's route table using the *vpc-id* you found previously.

```
aws ec2 describe-route-tables \
    --filters 'Name=vpc-id, Values=accountA-vpc-id' \
    --query 'RouteTables[0].RouteTableId'
```

9. From account A, add a route to send traffic destined for account B's CIDR to the VPC peering connection. Replace each *user input placeholder* with the correct values for your accounts.

```
aws ec2 create-route \
    --route-table-id accountA-route-table-id \
    --destination-cidr accountB-vpc-cidr \
    --vpc-peering-connection-id peering-connection-id
```

10. From account B, launch an EC2 instance in the VPC that you created earlier. Give it the `AssumeDaxInstanceProfile`. You can use either the launch wizard in the AWS Management Console or the AWS CLI. Take note of the instance's security group.
11. From account A, find the security group used by the DAX cluster. Remember to replace *cluster-name* with the name of your DAX cluster.

```
aws dax describe-clusters \
```

```
    --cluster-name cluster-name \
    --query 'Clusters[0].SecurityGroups[0].SecurityGroupIdentifier'
```

12. Update the DAX cluster's security group to allow inbound traffic from the security group of the EC2 instance you created in account B. Remember to replace the *user input placeholders* with the correct values for your accounts.

```
aws ec2 authorize-security-group-ingress \
    --group-id accountA-security-group-id \
    --protocol tcp \
    --port 8111 \
    --source-group accountB-security-group-id \
    --group-owner accountB-id
```

At this point, an application on account B's EC2 instance is able to use the instance profile to assume the `arn:aws:iam::`*accountA-id*`:role/DaxCrossAccountRole` role and use the DAX cluster.

Modify the DAX client to allow cross-account access

> **Note**
>
> AWS Security Token Service (AWS STS) credentials are temporary credentials. Some clients handle refreshing automatically, while others require additional logic to refresh the credentials. We recommend that you follow the guidance of the appropriate documentation.

Java

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the Java and DAX tutorial.

1. Add the following imports.

```
import com.amazonaws.auth.STSAssumeRoleSessionCredentialsProvider;
import com.amazonaws.services.securitytoken.AWSSecurityTokenService;
```

```
import
 com.amazonaws.services.securitytoken.AWSSecurityTokenServiceClientBuilder;
```

2. Get a credentials provider from AWS STS and create a DAX client object. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
AWSSecurityTokenService awsSecurityTokenService =
 AWSSecurityTokenServiceClientBuilder
     .standard()
     .withRegion(region)
     .build();

STSAssumeRoleSessionCredentialsProvider credentials =  new
 STSAssumeRoleSessionCredentialsProvider.Builder("arn:aws:iam::accountA:role/
RoleName", "TryDax")
     .withStsClient(awsSecurityTokenService)
     .build();

DynamoDB client = AmazonDaxClientBuilder.standard()
    .withRegion(region)
    .withEndpointConfiguration(dax_endpoint)
    .withCredentials(credentials)
    .build();
```

.NET

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the .NET and DAX tutorial.

1. Add the AWSSDK.SecurityToken NuGet package to the solution.

```
<PackageReference Include="AWSSDK.SecurityToken" Version="latest version" />
```

2. Use the `SecurityToken` and `SecurityToken.Model` packages.

```
using Amazon.SecurityToken;
using Amazon.SecurityToken.Model;
```

3. Get temporary credentials from `AmazonSimpleTokenService` and create a `ClusterDaxClient` object. Remember to replace each *`user input placeholder`* with the correct values for your accounts.

```
IAmazonSecurityTokenService sts = new AmazonSecurityTokenServiceClient();

var assumeRoleResponse = sts.AssumeRole(new AssumeRoleRequest
{
    RoleArn = "arn:aws:iam::accountA:role/RoleName",
                RoleSessionName = "TryDax"
});

Credentials credentials = assumeRoleResponse.Credentials;

var clientConfig = new DaxClientConfig(dax_endpoint, port)
{
    AwsCredentials = assumeRoleResponse.Credentials

};

var client = new ClusterDaxClient(clientConfig);
```

Go

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples on GitHub.

1. Import the AWS STS and session packages.

```
import (
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/sts"
    "github.com/aws/aws-sdk-go/aws/credentials/stscreds"
)
```

2. Get temporary credentials from `AmazonSimpleTokenService` and create a DAX client object. Remember to replace each *`user input placeholder`* with the correct values for your accounts.

```
sess, err := session.NewSession(&aws.Config{
    Region: aws.String(region)},
```

```
)
if err != nil {
    return nil, err
}

stsClient := sts.New(sess)
arp := &stscreds.AssumeRoleProvider{
                Duration:     900 * time.Second,
                ExpiryWindow: 10 * time.Second,
                RoleARN:      "arn:aws:iam::accountA:role/role_name",
                Client:       stsClient,
                RoleSessionName: "session_name",
        }cfg := dax.DefaultConfig()

cfg.HostPorts = []string{dax_endpoint}
cfg.Region = region
cfg.Credentials = credentials.NewCredentials(arp)
daxClient := dax.New(cfg)
```

Python

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the Python and DAX tutorial.

1. Import `boto3`.

```
import boto3
```

2. Get temporary credentials from `sts` and create an `AmazonDaxClient` object. Remember to replace each *`user input placeholder`* with the correct values for your accounts.

```
sts = boto3.client('sts')
stsresponse =
 sts.assume_role(RoleArn='arn:aws:iam::accountA:role/
RoleName',RoleSessionName='tryDax')
credentials = botocore.session.get_session()['Credentials']

dax = amazondax.AmazonDaxClient(session, region_name=region,
 endpoints=[dax_endpoint], aws_access_key_id=credentials['AccessKeyId'],
 aws_secret_access_key=credentials['SecretAccessKey'],
 aws_session_token=credentials['SessionToken'])
```

```
client = dax
```

Node.js

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the Node.js and DAX tutorial. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
const AmazonDaxClient = require('amazon-dax-client');
const AWS = require('aws-sdk');
const region = 'region';
const endpoints = [daxEndpoint1, ...];

const getCredentials = async() => {
  return new Promise((resolve, reject) => {
    const sts = new AWS.STS();
    const roleParams = {
      RoleArn: 'arn:aws:iam::accountA:role/RoleName',
      RoleSessionName: 'tryDax',
    };
    sts.assumeRole(roleParams, (err, session) => {
      if(err) {
        reject(err);
      } else {
        resolve({
          accessKeyId: session.Credentials.AccessKeyId,
          secretAccessKey: session.Credentials.SecretAccessKey,
          sessionToken: session.Credentials.SessionToken,
        });
      }
    });
  });
};

const createDaxClient = async() => {
  const credentials = await getCredentials();
  const daxClient = new AmazonDaxClient({endpoints: endpoints, region: region,
 accessKeyId: credentials.accessKeyId, secretAccessKey: credentials.secretAccessKey,
 sessionToken: credentials.sessionToken});
  return new AWS.DynamoDB.DocumentClient({service: daxClient});
};
```

```
createDaxClient().then((client) => {
  client.get(...);
  ...
}).catch((error) => {
  console.log('Caught an error: ' + error);
});
```

DAX cluster sizing guide

This guide provides advice for choosing an appropriate Amazon DynamoDB Accelerator (DAX) cluster size and node type for your application. These instructions guide you through the steps of estimating your application's DAX traffic, selecting a cluster configuration, and testing it.

If you have an existing DAX cluster and want to evaluate whether it has the appropriate number and size of nodes, please refer to Scaling a DAX cluster.

Topics

- Overview
- Estimating traffic
- Load testing

Overview

It's important to scale your DAX cluster appropriately for your workload, whether you're creating a new cluster or maintaining an existing cluster. As time goes on and your application's workload changes, you should periodically revisit your scaling decisions to make sure that they are still appropriate.

The process typically follows these steps:

1. **Estimating traffic.** In this step, you make predictions about the volume of traffic that your application will send to DAX, the nature of the traffic (read vs. write operations), and the expected cache hit rate.
2. **Load testing.** In this step, you create a cluster and send traffic to it mirroring your estimates from the previous step. Repeat this step until you find a suitable cluster configuration.

3. **Production monitoring.** While your application is using DAX in production, you should monitor the cluster to continuously validate that it is still scaled correctly as your workload changes over time.

Estimating traffic

There are three main factors that characterize a typical DAX workload:

- Cache hit rate
- Read capacity units (RCUs) per second
- Write capacity units (WCUs) per second

Estimating cache hit rate

If you already have a DAX cluster, you can use the `ItemCacheHits` and `ItemCacheMisses` Amazon CloudWatch metrics to determine the cache hit rate. The cache hit rate is equal to `ItemCacheHits` / (`ItemCacheHits` + `ItemCacheMisses`). If your workload includes `Query` or `Scan` operations, you should also look at the `QueryCacheHits`, `QueryCacheMisses`, `ScanCacheHits`, and `ScanCacheMisses` metrics. Cache hit rates vary from one application to another and are heavily influenced by the cluster's Time to Live (TTL) setting. Typical hit rates for applications using DAX are 85–95 percent.

Estimating read and write capacity units

If you already have DynamoDB tables for your application, look at the `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` CloudWatch metrics. Use the `Sum` statistic and divide by the number of seconds in the period.

If you also already have a DAX cluster, remember that the DynamoDB `ConsumedReadCapacityUnits` metric only accounts for cache misses. So, to get an idea of the read capacity units per second handled by your DAX cluster, divide the number by your cache miss rate (that is, 1 - cache hit rate).

If you don't already have a DynamoDB table, see the documentation about read and write capacity units to estimate your traffic based on your application's estimated request rate, items accessed per request, and item size.

When making traffic estimates, plan for future growth and for expected and unexpected peaks to make sure that your cluster has enough headroom for traffic increases.

Load testing

The next step after estimating traffic is to test the cluster configuration under load.

1. For your initial load test, we recommend that you start with the `dax.r4.large` node type, the lowest-cost fixed performance, memory-optimized node type.
2. A fault-tolerant cluster requires at least three nodes, spread across three Availability Zones. In this case, if an Availability Zone becomes unavailable, the effective number of Availability Zones is reduced by one-third. For your initial load test, we recommend that you start with a two-node cluster, which simulates the failure of one Availability Zone in a three-node cluster.
3. Drive sustained traffic (as estimated in the previous step) to your test cluster for the duration of the load test.
4. Monitor the performance of the cluster during the load test.

Ideally, the traffic profile that you drive during the load test should be as similar as possible to your application's real traffic. This includes the distribution of operations (for example, 70 percent `GetItem`, 25 percent `Query`, and 5 percent `PutItem`), the request rate for each operation, the number of items accessed per request, and the distribution of item sizes. To achieve a cache hit rate similar to your application's expected cache hit rate, pay close attention to the distribution of keys in your test traffic.

> **Note**
>
> Be careful when load testing T2 node types (`dax.t2.small` and `dax.t2.medium`). T2 node types provide burstable CPU performance that varies over time depending on the node's CPU credit balance. A DAX cluster running on T2 nodes might appear to be operating normally, but if any node is bursting above the baseline performance of its instance, the node is spending its accrued CPU credit balance. When the credit balance runs low, performance is gradually lowered to the baseline performance level.

Monitor your DAX cluster during the load test to determine whether the node type that you're using for the load test is the right node type for you. In addition, during a load test, you should

monitor your request rate and cache hit rate to make sure that your test infrastructure is actually driving the amount of traffic you intend.

You should pay attention to network bytes consumption of your selected cluster instance type. Exceeding the available baseline bandwidth for an Amazon EC2 instance indicates that your cluster might not sustain your application's workload, and needs to be scaled.

If load testing indicates that the selected cluster configuration can't sustain your application's workload, you should switch to a larger node type, especially if you see high CPU utilization on the primary node in the cluster, high eviction rates, or high cache memory utilization. If hit rates are consistently high, and the ratio of read to write traffic is high, you might want to consider adding more nodes to your cluster. Refer to Scaling a DAX cluster for additional guidance on when to use a larger node type (vertical scaling) or add more nodes (horizontal scaling).

You should repeat your load test after making changes to your cluster configuration.

Data modeling for DynamoDB tables

Before we dive into data modeling, it's important to understand some DynamoDB fundamentals. DynamoDB is a key-value NoSQL database which allows flexible schema. The set of data attributes apart from the key attributes for each item can be either uniform or discrete. The DynamoDB key schema is in the form of either a simple primary key where a partition key uniquely identifies an item, or in the form of a composite primary key where a combination of a partition key and sort key uniquely defines an item. The partition key is hashed to determine the physical location of data and retrieve it. Therefore, it is important to choose a high cardinality and horizontally scalable attribute as a partition key to ensure even distribution of data. The sort key attribute is optional in the key schema and having a sort key enables modelling one-to-many relationships and creating item collections in DynamoDB. Sort keys are also referred to as range keys—they are used to sort items in an item collection and also allow flexible range-based operations.

For more details and best practices on DynamoDB key schema, you can refer to the following:

- the section called “Partitions and data distribution in DynamoDB”
- the section called “Partition key design”
- the section called “Sort key design”
- Choosing the right DynamoDB partition key

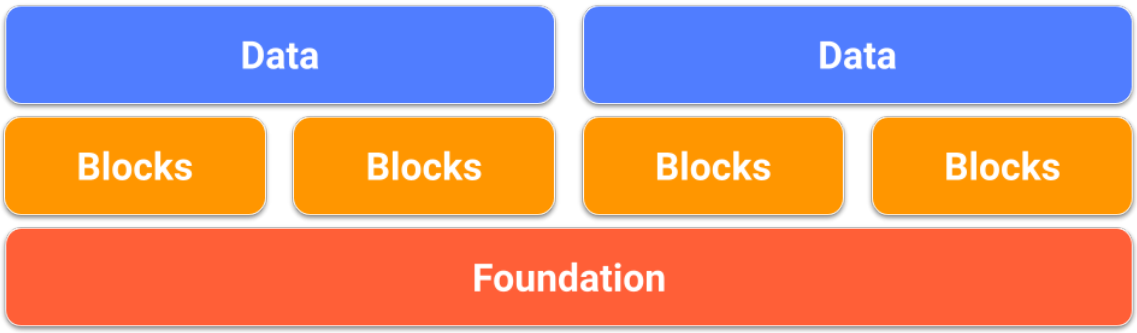
Secondary indexes are often needed to support additional query patterns in DynamoDB. Secondary indexes are shadow tables where the same data is organized through a different key schema compared to the base table. A local secondary index (LSI) shares the same partition key as the base table and allows having an alternate sort key allowing it to share the base table’s capacity. A global secondary index (GSI) can have a different partition key as well as a different sort key attribute than the base table which means throughput management for a GSI is independent of the base table.

For more details on secondary indexes and best practices, you can refer to the following:

- the section called “Working with secondary indexes”
- the section called “Secondary indexes”

Let's now look at data modeling a little closer. The process of designing a flexible and highly-optimized schema on DynamoDB, or any NoSQL database for that matter, can be a challenging

skill to learn. The goal of this module is to help you develop a mental flowchart for designing a schema that will take you from use case into production. We will start with an introduction to the foundational choice of any design, single table versus multiple table design. Then we will review the multitude of design patterns (building blocks) that can be used to achieve various organizational or performance results for your application. Finally, we are including a variety of complete schema design packages for different use cases and industries.



Topics

- Item collections - how to model one-to-many relationships in DynamoDB
- Data Modeling foundations in DynamoDB
- Data modeling building blocks in DynamoDB
- Data modeling schema design packages in DynamoDB
- Best practices for modeling relational data in DynamoDB

Item collections - how to model one-to-many relationships in DynamoDB

In DynamoDB, an *item collection* is a group of items that share the same partition key value, which means the items are related. Item collections are the primary mechanism to model one-to-many relationships in DynamoDB. Item collections can only exist on tables or indexes configured to use a composite primary key.

> **Note**
>
> Item collections can exist either in a base table or a secondary index. For more information specifically about how item collections interact with indexes, see Item collections in Local Secondary Indexes.

Consider the following table showing three different users and their in-game inventories:

Primary key		Attributes		
Partition key: PK	**Sort key: SK**			
account1234	inventory::armor	data		
		{"armor": [{"name" : "Pauldron of the Paladin", "type" : "chest", "gear score" : 545 }, { "name" : "Greaves of the Ranger", "type" : "sword", "gear score" : 382}]}		
	inventory::weapons	data

For some items in each collection, the sort key is a concatenation made up of information used to group data, such as `inventory::armor`, `inventory::weapon` or `info`. Each item collection can have a different combination of these attributes as the sort key. User `account1234` has an `inventory::weapons` item, while user `account1387` does not (because they have not found any yet). User `account1138` only uses two items for their sort key (since they have no inventory yet) while the other users use three.

DynamoDB lets you selectively retrieve items from these item collections to do the following:

- Retrieve all items from a particular user
- Retrieve only one item from a particular user
- Retrieve all the items of a specific type belonging to a particular user

Speed up queries by organizing your data with item collections

In this example, each of the items in these three item collections represents a player and the data model chosen for this example, based on the game's and player's access patterns. What data does the game need? When does it need it? How frequently does it need it? What's the cost of doing it this way? These data modeling decisions were made based on the answers to these questions.

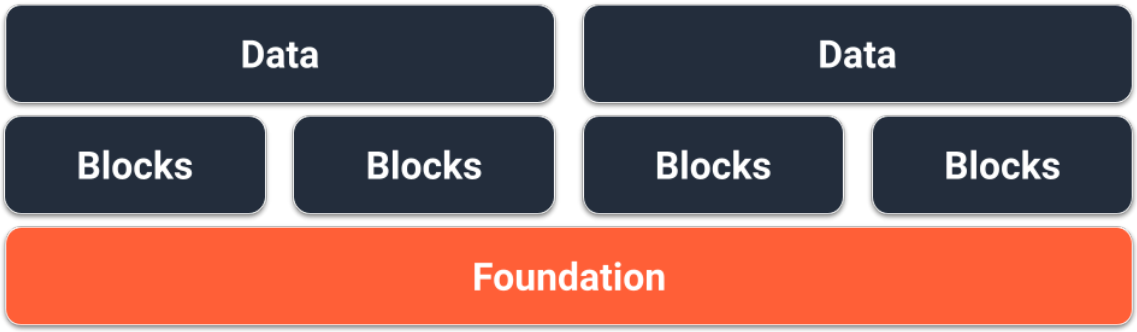
In this game, there is a different page presented to the player for their inventory for weapons and another page for armor. When the player opens their inventory, weapons are shown first because

that page needs to load extremely fast, while subsequent inventory pages can load after that. Since each of these item types can be quite large as the player acquires more in-game items, each inventory page is its own item in the player's item collection in the database.

The following section talks more about how you can interact with item collections through the `Query` operation.

Data Modeling foundations in DynamoDB

This section covers the foundation layer by examining the two types of table design: single table and multiple table.



Single table design foundation

One choice for the foundation of our DynamoDB schema is **single table design**. Single table design is a pattern that allows you to store multiple types (entities) of data in a single DynamoDB table. It aims to optimize data access patterns, improve performance, and reduce costs by eliminating the need for maintaining multiple tables and complex relationships between them. This is possible because DynamoDB stores items with the same partition key (known as an item collection) on the same partition(s) as each other. In this design, different types of data are stored as items in the same table, and each item is identified by a unique sort key.

Primary key		Attributes	
Partition key: PK	Sort key: SK		
UserID	Address#USA#CA#LA#90029	data	GSI-SK
		"Street Address"	Default
	Cart#ACTIVE#Coffee	data	GSI-SK
		CoffeeSKU	2019-11-27T103324
	Cart#ACTIVE#Spice	data	GSI-SK
		SpiceSKU	2019-11-28T091245
	Cart#SAVED#Cocoa	data	GSI-SK
		CocoaSKU	2019-11-28T125642
	OrderHistory#OrderUID	data	GSI-SK
		{Order:DataMap}	2019-10-08T132612
	ProfileName	data	
		"Paul Atreides"	
	Store#StoreUID	data	GSI-SK
		Los Angeles	Active

Advantages

- Data locality to support queries for multiple entity types in a single database call
- Reduces overall financial and latency costs of reads:
  - A single query for two items totalling less than 4KB is 0.5 RCU eventually consistent
  - Two queries for two items totalling less than 4KB is 1 RCU eventually consistent (0.5 RCU each)
  - The time to return two separate database calls will average higher than a single call
- Reduces the number of tables to manage:
  - Permissions do not need to be maintained across multiple IAM roles or policies
  - Capacity management for the table is averaged across all entities, usually resulting in a more predictable consumption pattern
  - Monitoring requires fewer alarms
  - Customer Managed Encryption Keys only need to be rotated on one table
- Smooths traffic to the table:
  - By aggregating multiple usage patterns to the same table, the overall usage tends to be smoother (the way a stock index's performance tends to be smoother than any individual stock) which works better for achieving higher utilization with provisioned mode tables

Disadvantages

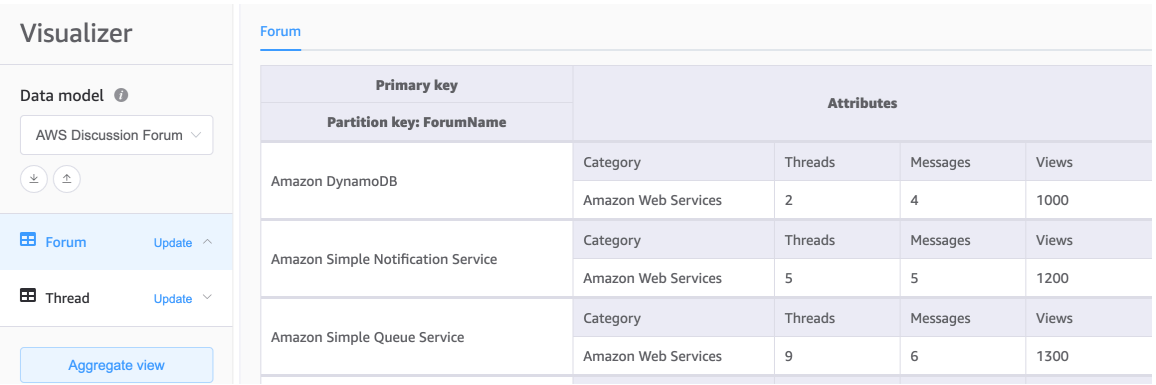
- Learning curve can be steep due to paradoxical design compared to relational databases
- Data requirements must be consistent across all entity types
  - Backups are all or nothing so if some data is not mission critical, consider keeping it in a separate table
  - Table encryption is shared across all items. For multi-tenant applications with individual tenant encryption requirements, client side encryption would be required
  - Tables with a mix of historical data and operational data will not see as much of a benefit from enabling the Infrequent Access Storage Class. For more information, see DynamoDB table classes
- All changed data will be propagated to DynamoDB Streams even if only a subset of entities need to be processed.
  - Thanks to Lambda event filters, this will not affect your bill when using Lambda, but will be an added cost when using the Kinesis Consumer Library
- When using GraphQL, single table design will be more difficult to implement
- When using higher-level SDK clients like Java's `DynamoDBMapper` or Enhanced Client, it can be more difficult to process results because items in the same response might be associated with different classes

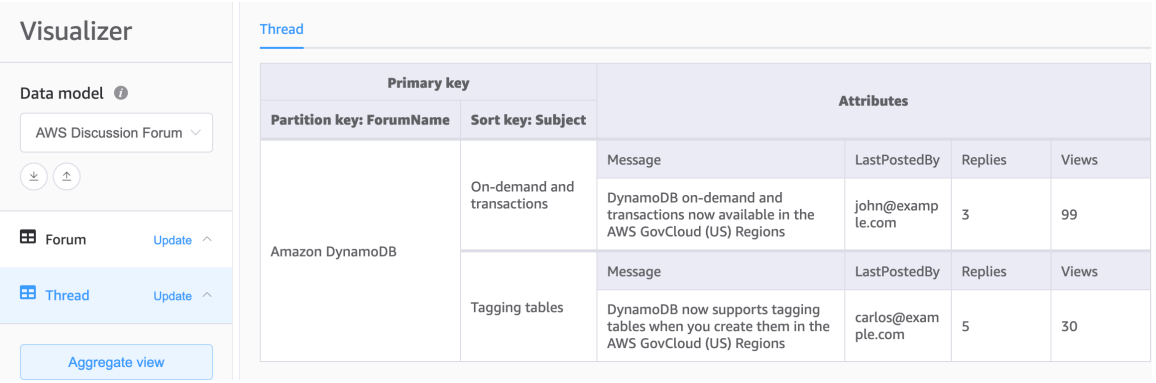
When to use

Single table design works well for applications that frequently query multiple entity types together or need to maintain relationships between different data types. It's particularly effective when your access patterns benefit from data locality and when you want to minimize the overhead of managing multiple tables.

Multiple table design foundation

The second choice for the foundation of our DynamoDB schema is multiple table design. Multiple table design is a pattern that is more like a traditional database design where you store a single type(entity) of data in a each DynamoDB table. Data within each table will still be organized by partition key so performance within a single entity type will be optimized for scalability and performance, but queries across multiple tables must be done independently.





Advantages

- Simpler to design for those who aren't used to working with single table design
- Easier implementation of GraphQL resolvers due to each resolver mapping to a single entity(table)
- Allows for unique data requirements across different entity types:
  - Backups can be made for the individual tables that are mission critical
  - Table encryption can be managed for each table. For multi-tenant applications with individual tenant encryption requirements, separate tenant tables make it possible for each customer to have their own encryption key
  - Infrequent Access Storage Class can be enabled on just the tables with historical data to realize the full cost savings benefit. For more information, see DynamoDB table classes
- Each table will have its own change data stream allowing for a dedicated Lambda function to be designed for each type of item rather than a single monolithic processor

Disadvantages

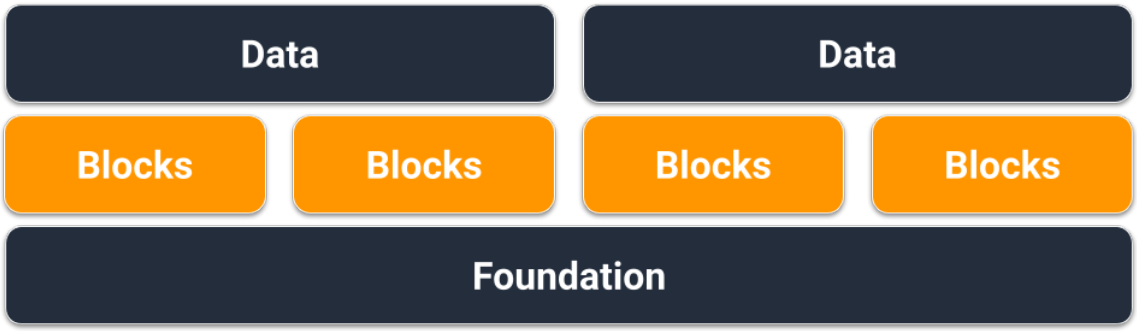
- For access patterns that require data across multiple tables, multiple reads from DynamoDB will be required and data might need to be processed/joined on the client code.
- Operations and monitoring of multiple tables requires more CloudWatch alarms and each table must be scaled independently
- Each tables permissions will need to be managed separately. The addition of tables in the future will require a change to any necessary IAM roles or policies

When to use

If your application's access patterns do not have the need to query multiple entities or tables together, then multiple table design is a good and sufficient approach.

Data modeling building blocks in DynamoDB

This section covers the building block layer to give you design patterns you can use in your application.



Topics

- Composite sort key building block
- Multi-tenancy building block
- Sparse index building block
- Time to live building block
- Time to live for archival building block
- Vertical partitioning building block
- Write sharding building block

Composite sort key building block

When people think of NoSQL, they may also think of it as non-relational. Ultimately, there is no reason relationships cannot be placed into a DynamoDB schema, they just look different than relational databases and their foreign keys. One of the most critical patterns we can use to develop a logical hierarchy of our data in DynamoDB is a composite sort key. The most common style for designing one is with each layer of the hierarchy (parent layer > child layer > grandchild layer) separated by a hashtag. For example, `PARENT#CHILD#GRANDCHILD#ETC`.

Partition key: PK	Sort key: SK
UserID	CART#ACTIVE#Apples
UserID	CART#ACTIVE#Bananas
UserID	CART#SAVED#Oranges
UserID	CART#SAVED#Pears
UserID	WISH#VEGGIES#Carrots

While a partition key in DynamoDB always requires the exact value to query for data, we can apply a partial condition to the sort key from left to right similar to traversing a binary tree.

In the example above, we have an e-Commerce store with a Shopping Cart that needs to be maintained across user sessions. Whenever the user logs in, they may want to see the entire Shopping Cart including items saved for later. But when they enter the checkout, only items in the active cart should be loaded for purchase. Since both of these `KeyConditions` explicitly ask for CART sort keys, the additional wishlist data is simply ignored by DynamoDB at read time. While both saved and active items are a part of the same cart, we need to treat them differently in different parts of the application, so applying a `KeyCondition` to the prefix of the sort key is the most optimized way of retrieving only the data needed for each part of the application.

Key features of this building block

- Related items are stored locally to each other for effective data access
- Using `KeyCondition` expressions, subsets of the hierarchy can be selectively retrieved meaning there are no wasted RCUs

- Different parts of the application can store their items under a specific prefix preventing overwritten items or conflicting writes

Multi-tenancy building block

Many customers use DynamoDB to host data for their multi-tenant applications. For these scenarios, we want to design the schema in a way that keeps all data from a single tenant in its own logical partition of the table. This leverages the concept of an Item Collection, which is a term for all items in a DynamoDB table with the same partition key. For more information on how DynamoDB approaches multitenancy, see Multitenancy on DynamoDB.

Partition key: PK	Sort key: SK	ImageURL
UserOne	PhotoID1	https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
UserOne	PhotoID2	https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
UserTwo	PhotoID3	https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
UserTwo	PhotoID4	https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
UserThree	PhotoID5	https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]

For this example, we are running a photo hosting site with potentially thousands of users. Each user will only upload photos to their own profile initially, but by default we will not allow a user to see the photos of any other user. An additional level of isolation would ideally be added to the authorization of each user's call to your API to make sure they are only requesting data from their own partition, but at the schema level, unique partition keys is adequate.

Key features of this building block

- The amount of data read by any one user or tenant can only be as much as the total amount of items in their partition
- Removal of a tenant's data due to an account closure or compliance request can be done tactfully and cheaply. Simply run a query where the partition key equals their tenant ID, then execute a `DeleteItem` operation for each primary key returned

> **Note**
>
> Designed with multi-tenancy in mind, you can use different encryption key providers across a single table to safely isolate data. AWS Database Encryption SDK for Amazon DynamoDB enables you to include client-side encryption in your DynamoDB workloads. You can perform attribute-level encryption, enabling you to encrypt specific attribute values before storing them in your DynamoDB table and search on encrypted attributes without decrypting the entire database beforehand.

Sparse index building block

Sometimes an access pattern requires looking for items that match a rare item or an item that receives a status (which requires an escalated response). Rather than regularly query across the entire dataset for these items, we can leverage the fact that **global secondary indexes (GSI)** are sparsely loaded with data. This means that only items in the base table that have the attributes defined in the index will be replicated to the index.

Partition key: DeviceID	Sort key: State#Date	Operator	Date	EscalatedTo
d#12345	NORMAL#2020-04-24T 14:55:00	Liz	2020-04-24	
d#12345	WARNING1#2020-04-2 4T14:45:00	Liz	2020-04-24	
d#12345	WARNING1#2020-04-2 4T14:50:00	Liz	2020-04-24	

Partition key: DeviceID	Sort key: State#Date	Operator	Date	EscalatedTo
d#54321	NORMAL#2020-04-11T 06:00:00	Liz	2020-04-11	
d#54321	NORMAL#2020-04-11T 09:30:00	Sue	2020-04-11	
d#54321	WARNING2#2020-04-1 1T09:25:00	Sue	2020-04-11	
d#54321	WARNING3#2020-04-1 1T05:55:00	Liz	2020-04-11	
d#11223	WARNING4#2020-04-2 7T16:10:00	Sue	2020-04-27	
d#11223	WARNING4#2020-04-2 7T16:15:00	Sue	2020-04-27	Sara

Partition key: EscalatedTo	Sort key: State#Date	DeviceID	Operator
Sara	WARNING4#2020-04-27T16:15:00	d#11223	Sue

In this example, we see an IOT use case where each device in the field is reporting back a status on a regular basis. For the majority of the reports we expect the device to report everything is okay, but on occasion there can be a fault and it must be escalated to a repair technician. For reports with an escalation, the attribute `EscalatedTo` is added the item, but is not present otherwise. The GSI in this example is partitioned by `EscalatedTo` and since the GSI brings over keys from the base table we can still see which DeviceID reported the fault and at what time.

While reads are cheaper than writes in DynamoDB, sparse indexes are a very powerful tool for use cases where instances of a specific type of item is rare but reads to find them are common.

Key features of this building block

- Write and storage costs for the sparse GSI only apply to items that match the key pattern, so the cost of the GSI can be substantially less than other GSIs that have all items replicated to them
- A composite sort key can still be used to further narrow down the items that match the desired query, for instance, a timestamp could be used for the sort key to only view faults reported in the last X minutes (`SK > 5 minutes ago, ScanIndexForward: False`)

Time to live building block

Most data have some duration of time for which it can be considered worth keeping in a primary datastore. To facilitate data aging out from DynamoDB, it has a feature called **time to live (TTL)**. The TTL feature allows you to define a specific attribute at the table level that needs monitoring for items with an epoch timestamp (that's in the past). This allows you to delete expired records from the table for free.

> **Note**
>
> If you are using Global Tables version 2019.11.21 (Current) of global tables and you also use the Time to Live feature, DynamoDB replicates TTL deletes to all replica tables. The initial TTL delete does not consume write capacity in the Region in which the TTL expiry occurs. However, the replicated TTL delete to the replica table(s) consumes replicated write capacity in each of the replica Regions and applicable charges will apply.

Partition key: PK	Sort key: MessageTimestamp	TTL	Message
UserID	2030-06-30T12:12:12	1909570332	Hello
UserID	2030-06-30T12:17:22	1909570647	DynamoDB
UserID	2030-06-30T12:22:27	1909570947	TTL

In this example, we have an application designed to let a user create messages that are short-lived. When a message is created in DynamoDB, the TTL attribute is set to a date seven days in the future

by the application code. In roughly seven days, DynamoDB will see that the epoch timestamp of these items is in the past and delete them.

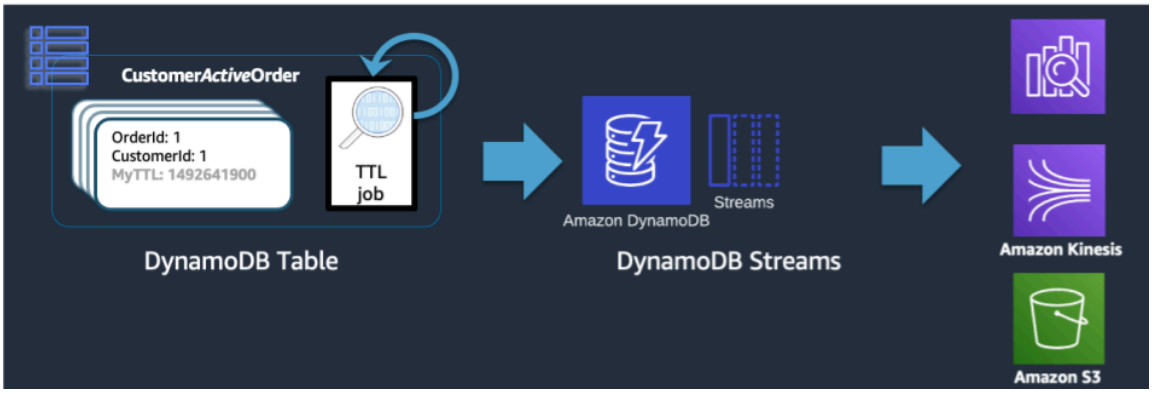
Since the deletes done by TTL are free, it is strongly recommended to use this feature to remove historical data from the table. This will reduce the overall storage bill each month and will likely reduce the costs of user reads since there will be less data to be retrieved by their queries. While TTL is enabled at the table level, it is up to you which items or entities to create a TTL attribute for and how far into the future to set the epoch timestamp to.

Key features of this building block

- TTL deletes are run behind the scenes with no impact to your table performance
- TTL is an asynchronous process that runs roughly every six hours, but can take over 48 hours for an expired record to be deleted
  - Do not rely on TTL deletes for use cases like lock records or state management if stale data must be cleaned up in less than 48 hours
- You can name the TTL attribute a valid attribute name, but the value must be a number type

Time to live for archival building block

While TTL is an effective tool for deleting older data from DynamoDB, many use cases require an archive of the data be kept for a longer period of time than the primary datastore. In this instance, we can leverage TTL's timed deletion of records to push expired records into a long-term datastore.



When a TTL delete is done by DynamoDB, it is still pushed into the DynamoDB Stream as a `Delete` event. When DynamoDB TTL is the one who performs the delete though, there is an attribute on the stream record of `principal:dynamodb`. Using a Lambda subscriber to the DynamoDB Stream, we can apply an event-filter for only the DynamoDB principal attribute and know that any records that match that filter are to be pushed to an archival store like Amazon Glacier.

Key features of this building block

- Once the low-latency reads of DynamoDB are no longer needed for the historical items, migrating them to a colder storage service like Amazon Glacier can reduce storage costs significantly while meeting the data compliance needs of your use case
- If the data is persisted into Amazon S3, cost-efficient analytics tools like Amazon Athena or Redshift Spectrum can be used to perform historical analysis of the data

Vertical partitioning building block

Users familiar with a document model database will be familar with the idea of storing all related data within a single JSON document. While DynamoDB supports JSON data types, it doesn't support executing `KeyConditions` on nested JSON. Since `KeyConditions` are what dictate how much data is read from disk and effectively how many RCUs a query consumes, this can result in inefficiencies at scale. To better optimize the writes and reads of DynamoDB, we recommend breaking apart the document's individual entities into individual DynamoDB items, also referred to as **vertical partitioning**.

For example, consider the following single JSON document that stores a user's profile, store, shopping cart, shipping address, and order history together:

```
{
    "UserProfile": {
        "FirstName": "Paul",
        "LastName": "Atreides",
        "DateJoined": "1965-08-01"
    },
    "Store": {
        "store_id": "STOREUID",
        "city": "Los Angeles",
        "zip_code": "90029"
    },
    "ShoppingCart": [
        { "Spice": { "SKU": "SpiceSKU", "CategoryID": "FictionalSpice", "DateAdded":
 "2019-06-11" } },
        { "EspressoBeans": { "SKU": "CaffeineSKU", "CategoryID": "FOODANDDRINK",
 "DateAdded": "2019-06-10" } }
    ],
    "ShippingAddress": {
        "street_address": "1234 Arrakis Dr",
```

```
        "city": "Los Angeles",
        "zip_code": "90029",
        "status": "default"
    },
    "OrderHistory#OrderUID": {
        "ProductA": "SKU_A",
        "ProductB": "SKU_B",
        "DateOrdered": "2018-09-28"
    }
}
```

Using vertical partitioning, the single document is broken apart into individual items that share the same partition key (`UserID`) but use a sort key prefix to identify each entity. The following table shows the same data stored as separate items:

Partition key: UserID	Sort key: SK	Attributes
UserID	UserProfile	FirstName: Paul, LastName: Atreides, DateJoined: 1965-08-01
UserID	Store#STOREUID	city: Los Angeles, zip_code: 90029
UserID	Cart#ACTIVE#Spice	SKU: SpiceSKU, CategoryID: FictionalSpice, DateAdded: 2019-06-11
UserID	Cart#ACTIVE#EspressoBeans	SKU: CaffeineSKU, CategoryID: FOODANDDRINK, DateAdded: 2019-06-10
UserID	Address#default	street_address: 1234 Arrakis Dr, city: Los Angeles, zip_code: 90029, status: default
UserID	OrderHistory#OrderUID	ProductA: SKU_A, ProductB: SKU_B, DateOrdered: 2018-09-28

Vertical partitioning, as shown above, is a key example of single table design in action but can also be implemented across multiple tables if desired. Since DynamoDB bills writes in 1KB increments, you should ideally partition the document in a way that results in items under 1KB.

Key features of this building block

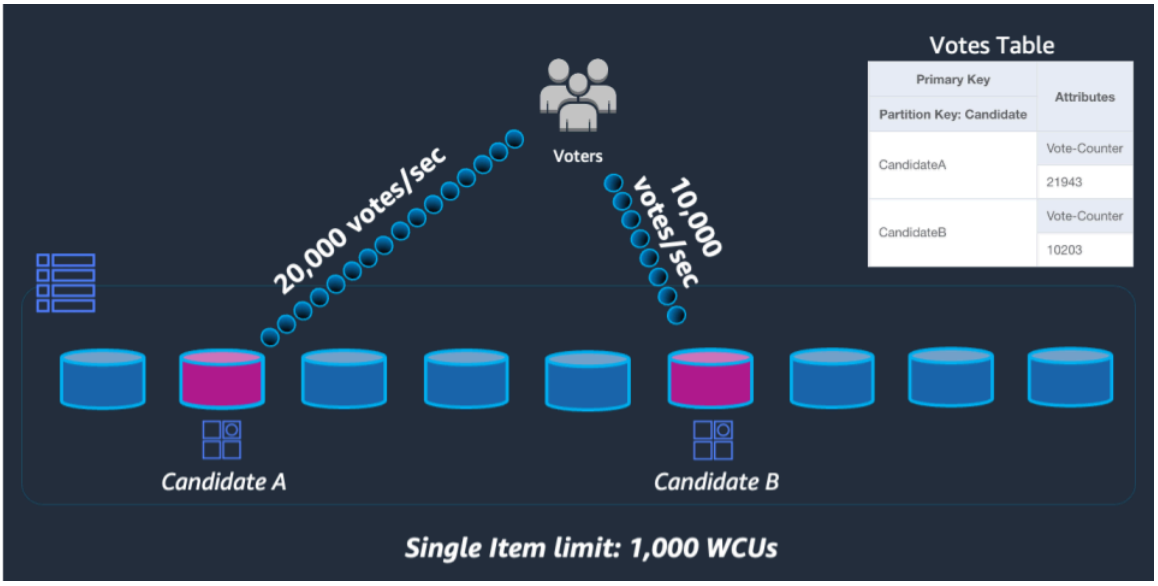
- A hierarchy of data relationships is maintained through sort key prefixes so the singular document structure could be rebuilt client-side if needed
- Singular components of the data structure can be updated independently resulting in small item updates being only 1 WCU
- By using the sort key `BeginsWith`, the application can retrieve similar data in a single query, aggregating read costs for reduced total cost/latency
- Large documents can easily be larger than the 400 KB individual item size limit in DynamoDB and vertical partitioning helps work around this limit

Write sharding building block

One of the very few hard limits DynamoDB has in place is the restriction of how much throughput a single physical partition can maintain per second (not necessarily a single partition key). These limits are presently:

- 1000 WCU (or 1000 <=1KB items written per second) and 3000 RCU (or 3000 <=4KB reads per second) *strongly consistent* or
- 6000 <=4KB reads per second *eventually consistent*

In the event requests against the table exceed either of these limits, an error is sent back to the client SDK of `ThroughputExceededException`, more commonly referred to as throttling. Use cases that require read operations beyond that limit will mostly be served best by placing a read cache in front of DynamoDB, but write operations require a schema level design known as **write sharding**.



Partition key: Candidate	Vote-Counter	Last-Update
CandidateA#1	10238	2019-09-30T11:35:53
CandidateA#2	8452	2019-09-30T11:35:53
CandidateA#3	9148	2019-09-30T11:35:53
CandidateA#4	11092	2019-09-30T11:35:53

To solve this problem, we'll append a random integer onto the end of the partition key for each contestant in the application's `UpdateItem` code. The range of the random integer generator will need to have an upper bound matching or exceeding the expected amount of writes per second for a given contestant divided by 1000. To support 20,000 votes per second, it would look like rand(0,19). Now that the data is stored under separate logical partitions, it must be combined back together at read time. Since vote totals doesn't need to be real time, a Lambda function scheduled to read all vote partitions every X minutes could perform occasional aggregation for each contestant and write it back to a single vote total record for live reads.

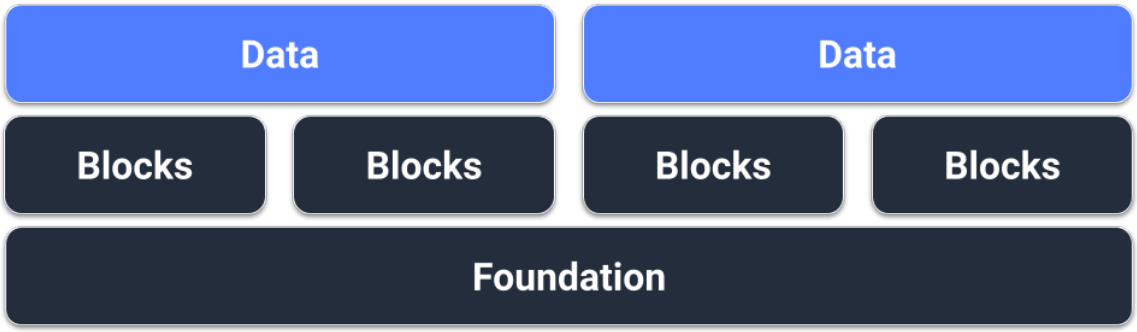
Key features of this building block

- For use cases with extremely high write throughput for a given partition key that cannot be avoided, write operations can be artificially spread across multiple DynamoDB partitions

- GSIs with a low cardinality partition key should also utilize this pattern since throttling on a GSI will apply backpressure to write operations on the base table

Data modeling schema design packages in DynamoDB

Learn about data modeling schema design packages for DynamoDB, including use cases, access patterns, and final schema designs for social networks, gaming profiles, complaint management, recurring payments, device status, and online shops.



Prerequisites

Before you attempt to design your schema for DynamoDB, you must first gather some prerequisite data on the use case the schema needs to support. Unlike relational databases, DynamoDB is sharded by default, meaning that the data will live on multiple servers behind the scenes so designing for data locality is important. You need to put together the following list for each schema design:

- List of entities (ER Diagram)
- Estimated volumes and throughput for each entity
- Access patterns that need to be supported (queries and writes)
- Data retention requirements

Topics

- Social network schema design in DynamoDB
- Gaming profile schema design in DynamoDB
- Complaint management system schema design in DynamoDB
- Recurring payments schema design in DynamoDB

- Monitoring device status updates in DynamoDB
- Using DynamoDB as a data store for an online shop

Social network schema design in DynamoDB

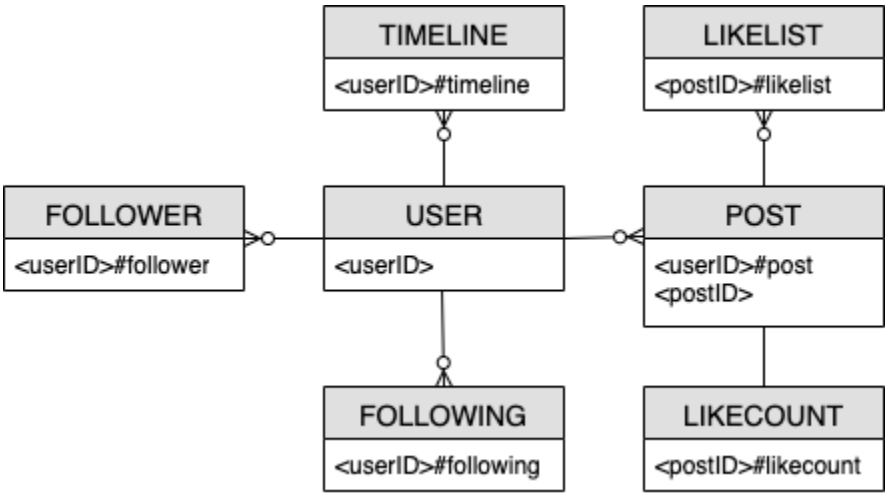
Social network business use case

This use case talks about using DynamoDB as a social network. A social network is an online service that lets different users interact with each other. The social network we'll design will let the user see a timeline consisting of their posts, their followers, who they are following, and the posts written by who they are following. The access patterns for this schema design are:

- Get user information for a given userID
- Get follower list for a given userID
- Get following list for a given userID
- Get post list for a given userID
- Get user list who likes the post for a given postID
- Get the like count for a given postID
- Get the timeline for a given userID

Social network entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the social network schema design.



Social network access patterns

These are the access patterns we'll be considering for the social network schema design.

- `getUserInfoByUserID`
- `getFollowerListByUserID`
- `getFollowingListByUserID`
- `getPostListByUserID`
- `getUserLikesByPostID`
- `getLikeCountByPostID`
- `getTimelineByUserID`

Social network schema design evolution

DynamoDB is a NoSQL database, so it does not allow you to perform a join - an operation that combines data from multiple databases. Customers unfamiliar with DynamoDB might apply relational database management system (RDBMS) design philosophies (such as creating a table for each entity) to DynamoDB when they do not need to. The purpose of DynamoDB's single-table design is to write data in a pre-joined form according to the application's access pattern, and then immediately use the data without additional computation. For more information, see Single-table vs. multi-table design in DynamoDB.

Now, let's step through how we'll evolve our schema design to address all the access patterns.

Step 1: Address access pattern 1 (`getUserInfoByUserID`)

To get a given user's information, we'll need to `Query` the base table with a key condition of `PK=<userID>`. The query operation lets you paginate the results, which can be useful when a user has many followers. For more information on Query, see Querying tables in DynamoDB.

In our example, we track two types of data for our user: their "count" and their "info." A user's "count" reflects how many followers they have, how many users they are following, and how many posts they've created. A user's "info" reflects their personal information such as their name.

We see these two kinds of data represented by the two items below. The item that has "count" in its sort key (SK) is more likely to change than the item with "info." DynamoDB considers the size of

the item as it appears before and after the update and the provisioned throughput consumed will reflect the larger of these item sizes. So even if you update just a subset of the item's attributes, `UpdateItem` will still consume the full amount of provisioned throughput (the larger of the before and after item sizes). You can get the items with a single `Query` operation and use `UpdateItem` to add or subtract from existing numeric attributes.

Primary key		Attributes			
Partition key: PK	**Sort key: SK**				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...

Step 2: Address access pattern 2 (`getFollowerListByUserID`)

To get a list of users who are following a given user, we'll need to `Query` the base table with a key condition of `PK=<userID>#follower`.

Primary key		Attributes			
Partition key: PK	**Sort key: SK**				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				

Step 3: Address access pattern 3 (`getFollowingListByUserID`)

To get a list of users a given user is following, we'll need to `Query` the base table with a key condition of `PK=<userID>#following`. You can then use a `TransactWriteItems` operation to group up several requests together and do the following:

- Add User A to User B's follower list, and then increment User B's follower count by one.
- Add User B to User A's follower list, and then increment User A's follower count by one.

Primary key		Attributes			
Partition key: PK	Sort key: SK				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				

Step 4: Address access pattern 4 (`getPostListByUserID`)

To get a list of posts created by a given user, we'll need to `Query` the base table with a key condition of `PK=<userID>#post`. One important thing to note here is that a user's postIDs must be incremental: the second postID value must be greater than the first postID value (since users want to see their posts in a sorted manner). You can do this by generating postIDs based on a time value like a Universally Unique Lexicographically Sortable Identifier (ULID).

Primary key		Attributes			
Partition key: PK	Sort key: SK				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	

Step 5: Address access pattern 5 (`getUserLikesByPostID`)

To get a list of users who liked a given user's post, we'll need to `Query` the base table with a key condition of `PK=<postID>#likelist`. This approach is the same pattern that we used for retrieving the follower and following lists in access pattern 2 (`getFollowerListByUserID`) and access pattern 3 (`getFollowingListByUserID`).

Primary key		Attributes			
Partition key: PK	**Sort key: SK**				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	
p#12345#likelist	u#23456				
	u#34567				
	u#45678				

Step 6: Address access pattern 6 (`getLikeCountByPostID`)

To get a count of likes for a given post, we'll need to perform a `GetItem` operation on the base table with a key condition of `PK=<postID>#likecount`. This access pattern can cause throttling issues whenever a user with many followers (such as a celebrity) creates a post since throttling occurs when a partition's throughput exceeds 1000 WCU per second. This problem is not a result of DynamoDB, it just appears in DynamoDB since it's at the end of the software stack.

You should evaluate whether it's really essential for all users to view the like count simultaneously or if it can happen gradually over time. In general, a post's like count doesn't need to be immediately 100% accurate. You can implement this strategy by putting a queue between your application and DynamoDB to have the updates happen periodically.

Primary key		Attributes			
Partition key: PK	**Sort key: SK**				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	
p#12345#likelist	u#23456				
	u#34567				
	u#45678				
p#12345#likecount	"count"	etc			
		100			

Step 7: Address access pattern 7 (`getTimelineByUserID`)

To get the timeline for a given user, we'll need to perform a `Query` operation on the base table with a key condition of `PK=<userID>#timeline`. Let's consider a scenario where a user's followers need to view their post synchronously. Every time a user writes a post, their follower list is read and their userID and postID are slowly entered into the timeline key of all its followers. Then, when your application starts, you can read the timeline key with the `Query` operation and fill the timeline screen with a combination of userID and postID using the `BatchGetItem` operation for any new items. You cannot read the timeline with an API call, but this is a more cost effective solution if the posts could be edited frequently.

The timeline is a place that shows recent posts, so we'll need a way to clean up the old ones. Instead of using WCU to delete them, you can use DynamoDB's TTL feature to do it for free.

Primary key		Attributes			
Partition key: PK	**Sort key: SK**				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	
p#12345#likelist	u#23456				
	u#34567				
	u#45678				
p#12345#likecount	"count"	etc			
		100			
u#12345#timeline	p#34567#u#56789	ttl			
		1571827560			
	p#45678#u#67890	ttl			
		1571827560			
	p#56789#u#78901	ttl			
		1571827560			

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getUserInfoByUserID	Base table	Query	PK=<userID>		

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getFollowerListByUserID	Base table	Query	PK=<userID>#follower		
getFollowingListByUserID	Base table	Query	PK=<userID>#following		
getPostListByUserID	Base table	Query	PK=<userID>#post		
getUserLikesByPostID	Base table	Query	PK=<postID>#likelist		
getLikeCountByPostID	Base table	GetItem	PK=<postID>#likecount		
getTimelineByUserID	Base table	Query	PK=<userID>#timeline		

Social network final schema

Here is the final schema design. To download this schema design as a JSON file, see DynamoDB Examples on GitHub.

Base table:

Primary key		Attributes			
Partition key: PK	**Sort key: SK**

Using NoSQL Workbench with this schema design

You can import this final schema into NoSQL Workbench, a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see the section called “Download”.
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see the section called “Importing an existing model”.

4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see the section called “Editing an existing model”.

Gaming profile schema design in DynamoDB

Gaming profile business use case

This use case talks about using DynamoDB to store player profiles for a gaming system. Users (in this case, players) need to create profiles before they can interact with many modern games, especially online ones. Gaming profiles typically include the following:

- Basic information such as their user name
- Game data such as items and equipment
- Game records such as tasks and activities
- Social information such as friend lists

To meet the fine-grained data query access requirements for this application, the primary keys (partition key and sort key) will use generic names (PK and SK) so they can be overloaded with various types of values as we will see below.

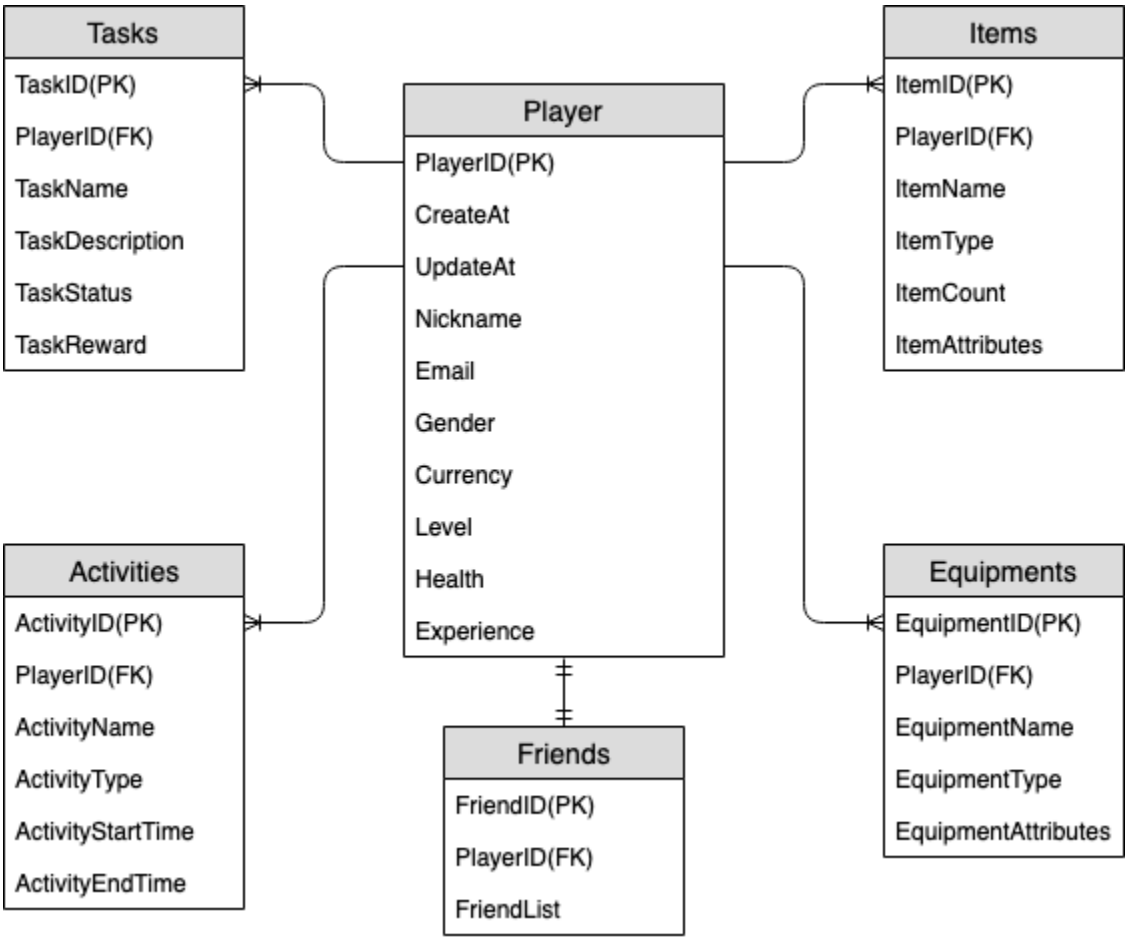
The access patterns for this schema design are:

- Get a user's friend list
- Get all of a player's information
- Get a user's item list
- Get a specific item from the user's item list
- Update a user's character
- Update the item count for a user

The size of the gaming profile will vary in different games. Compressing large attribute values can let them fit within item limits in DynamoDB and reduce costs. The throughput management strategy would depend various on factors such as: number of players, number of games played per second, and seasonality of the workload. Typically for a newly launched game, the number of players and the level of popularity are unknown so we will start with the on-demand throughput mode.

Gaming profile entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the gaming profile schema design.



Gaming profile access patterns

These are the access patterns we'll be considering for the social network schema design.

- `getPlayerFriends`
- `getPlayerAllProfile`
- `getPlayerAllItems`
- `getPlayerSpecificItem`
- `updateCharacterAttributes`
- `updateItemCount`

Gaming profile schema design evolution

From the above ERD, we can see that this is a one-to-many relationship type of data modeling. In DynamoDB, one-to-many data models can be organized into item collections, which is different from traditional relational databases where multiple tables are created and linked through foreign keys. An item collections is a group of items that share the same partition key value but have different sort key values. Within an item collection, each item has a unique sort key value that distinguishes it from other items. With this in mind, let's use the following pattern for HASH and RANGE values for each entity type.

To begin, we use generic names like PK and SK to store different types of entities in the same table to make the model future-proof. For better readability, we can include prefixes to denote the type of data or include an arbitrary attribute called `Entity_type` or `Type`. In the current example, we use a string starting with `player` to store `player_ID` as the PK; use `entity name#` as the prefix of SK, and add a `Type` attribute to indicate which entity type this piece of data is. This allows us to support storing more entity types in the future, and use advanced technologies such as GSI Overloading and Sparse GSI to meet more access patterns.

Let's start implementing the access patterns. Access patterns such as adding players and adding equipment can be realized through the `PutItem` operation, so we can ignore them. In this document, we'll focus on the typical access patterns listed above.

Step 1: Address access pattern 1 (`getPlayerFriends`)

We address access pattern 1 (`getPlayerFriends`) with this step. In our current design, friendship is simple and the number of friends in the game is small. For simplicity's sake, we use a list data type to store friend lists (1:1 modeling). In this design, we use `GetItem` to satisfy this access pattern. In the `GetItem` operation, we explicitly provide the partition key and sort key value to get a specific item.

However, if a game has a large number of friends, and the relationships between them are complex (such as friendships being bi-directional with both an invite and accept component) it would be necessary to use a many-to-many relationship to store each friend individually, in order to scale to an unlimited friend list size. And if the friendship change involves operating on multiple items at the same time, DynamoDB transactions can be used to group multiple actions together and submit them as a single all-or-nothing `TransactWriteItems` or `TransactGetItems` operation.

Primary key		Attributes	
Partition key: PK	Sort key: SK		
player001	FRIENDS#player001	Type	FriendList
		Friends	[{"M": {"FriendId": {"S":"player002"},"FriendName": {"S":"Alice"}}}, {"M":{"FriendId": {"S":"player003"},"FriendName": {"S":"Bob"}}}]

Step 2: Address access patterns 2 (`getPlayerAllProfile`), 3 (`getPlayerAllItems`), and 4 (`getPlayerSpecificItem`)

We address access patterns 2 (`getPlayerAllProfile`), 3 (`getPlayerAllItems`), and 4 (`getPlayerSpecificItem`) using this step. What these three access patterns have in common is a range query, which uses the `Query` operation. Depending on the scope of the query, Key Condition and Filter Expressions are used, which are commonly used in practical development.

In the Query operation, we provide a single value for Partition Key and get all items with that Partition Key value. Access pattern 2 (`getPlayerAllProfile`) is implemented in this way. Optionally, we can add a sort key condition expression — a string that determines the items to be read from the table. Access pattern 3 (`getPlayerAllItems`) is implemented by adding the key condition of sort key begins_with `ITEMS#`. Further, in order to simplify the development of the application side, we can use filter expressions to implement access pattern 4 (`getPlayerSpecificItem`).

Here's a pseudocode example using filter expression that filters items of the `Weapon` category:

```
filterExpression: "ItemType = :itemType"
expressionAttributeValues: {":itemType": "Weapon"}
```

Primary key		Attributes				
Partition key: PK	**Sort key: SK**					
player001	ITEMS#001	Type	ItemName	ItemType	ItemCount	ItemAttributes
		Item	Health Potion	Consumable	5	{"M":{"HP":{"N":"50"}}}
	ITEMS#002	Type	ItemName	ItemType	ItemCount	ItemAttributes
		Item	Armor of the Knight	Armor	1	{"M":{"DEF":{"N":"100"}}}
	ITEMS#003	Type	ItemName	ItemType	ItemCount	ItemAttributes
		Item	Sword of the Dragon	Weapon	1	{"M":{"ATK":{"N":"100"},"DEF":{"N":"50"}}}

> **Note**
>
> A filter expression is applied after a Query finishes, but before the results are returned to the client. Therefore, a Query consumes the same amount of read capacity regardless of whether a filter expression is present.

If the access pattern is to query a large dataset and filter out a large amount of data to keep only a small subset of data, the appropriate approach is to design DynamoDB Partition Key and Sort Key more effectively. For example, in the above example for obtaining a certain `ItemType`, if there are many items for each player and querying for a certain `ItemType` is a typical access pattern, it would be more efficient to bring `ItemType` into the SK as a composite key. The data model would look like this: `ITEMS#ItemType#ItemId`.

Step 3: Address access patterns 5 (`updateCharacterAttributes`) and 6 (`updateItemCount`)

We address access patterns 5 (`updateCharacterAttributes`) and 6 (`updateItemCount`) using this step. When the player needs to modify the character, such as reducing the currency, or modifying the quantity of a certain weapon in their items, use `UpdateItem` to implement these access patterns. To update a player's currency but make sure it never goes below a minimum amount, we can add a the section called “CLI example” to reduce the balance only if it's greater than or equal to the minimum amount. Here is a pseudocode example:

```
UpdateExpression: "SET currency = currency - :amount"
ConditionExpression: "currency >= :minAmount"
```

Primary key		Attributes									
Partition key: PK	Sort key: SK	Type	CreatedAt	UpdatedAt	Nickname	Email	Gender	Avatar	Currency	PlayerLevel	PlayerHealth	PlayerExperience
player001	#METADATA #player001	Metadata	1618500000	1620000000	John	john@example.com	male	s3://gaming-blki65wn3bgc-lob-avatar/player001.png	500 Updated to 500-Amount	10	80	1000

When developing with DynamoDB and using Atomic Counters to decrement inventory, we can ensure idempotency by using optimistic locking. Here is a pseudocode example for Atomic Counters:

```
UpdateExpression: "SET ItemCount = ItemCount - :incr"
expression-attribute-values: '{":incr":{"N":"1"}}'
```

Primary key		Attributes				
Partition key: PK	Sort key: SK	Type	ItemName	ItemType	ItemCount	ItemAttributes
player001	ITEMS#001	Item	Health Potion	Consumable	5 Updated to 4	{"M":{"HP":{"N":"50"}}}

In addition, in a scenario where the player purchases an item with currency, the entire process needs to deduct currency and add an item at the same time. We can use DynamoDB Transactions to group multiple actions together and submit them as a single all-or-nothing `TransactWriteItems` or `TransactGetItems` operation. `TransactWriteItems` is a synchronous and idempotent write operation that groups up to 100 write actions in a single all-or-nothing operation. The actions are completed atomically so that either all of them succeed or none of them succeeds. Transactions help eliminate the risk of duplication or vanishing currency. For more information on transactions, see DynamoDB transactions example .

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getPlayer Friends	Base table	GetItem	PK=PlayerID	SK="FRIENDS#playerID"	

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getPlayer AllProfile	Base table	Query	PK=PlayerID		
getPlayer AllItems	Base table	Query	PK=PlayerID	SK begins_with “ITEMS#”	
getPlayer SpecificItem	Base table	Query	PK=PlayerID	SK begins_with “ITEMS#”	filterExpression: "ItemType = :itemType " expressionAttributeValues: { ":itemType": "Weapon" }
updateCharacterAttributes	Base table	UpdateItem	PK=PlayerID	SK=“#METADATA#playerID”	UpdateExpression: "SET currency = currency - :amount" ConditionExpression: "currency >= :minAmount"

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
updateItemCount	Base table	UpdateItem	PK=PlayerID	SK =“ITEMS#ItemID”	update-expression: "SET ItemCount = ItemCount - :incr" expression-attribute-values : '{":incr": {"N":"1"}}'

Gaming profile final schema

Here is the final schema design. To download this schema design as a JSON file, see DynamoDB Examples on GitHub.

Using NoSQL Workbench with this schema design

You can import this final schema into NoSQL Workbench, a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see the section called “Download”.
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see the section called “Importing an existing model”.
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see the section called “Editing an existing model”.

Complaint management system schema design in DynamoDB

Complaint management system business use case

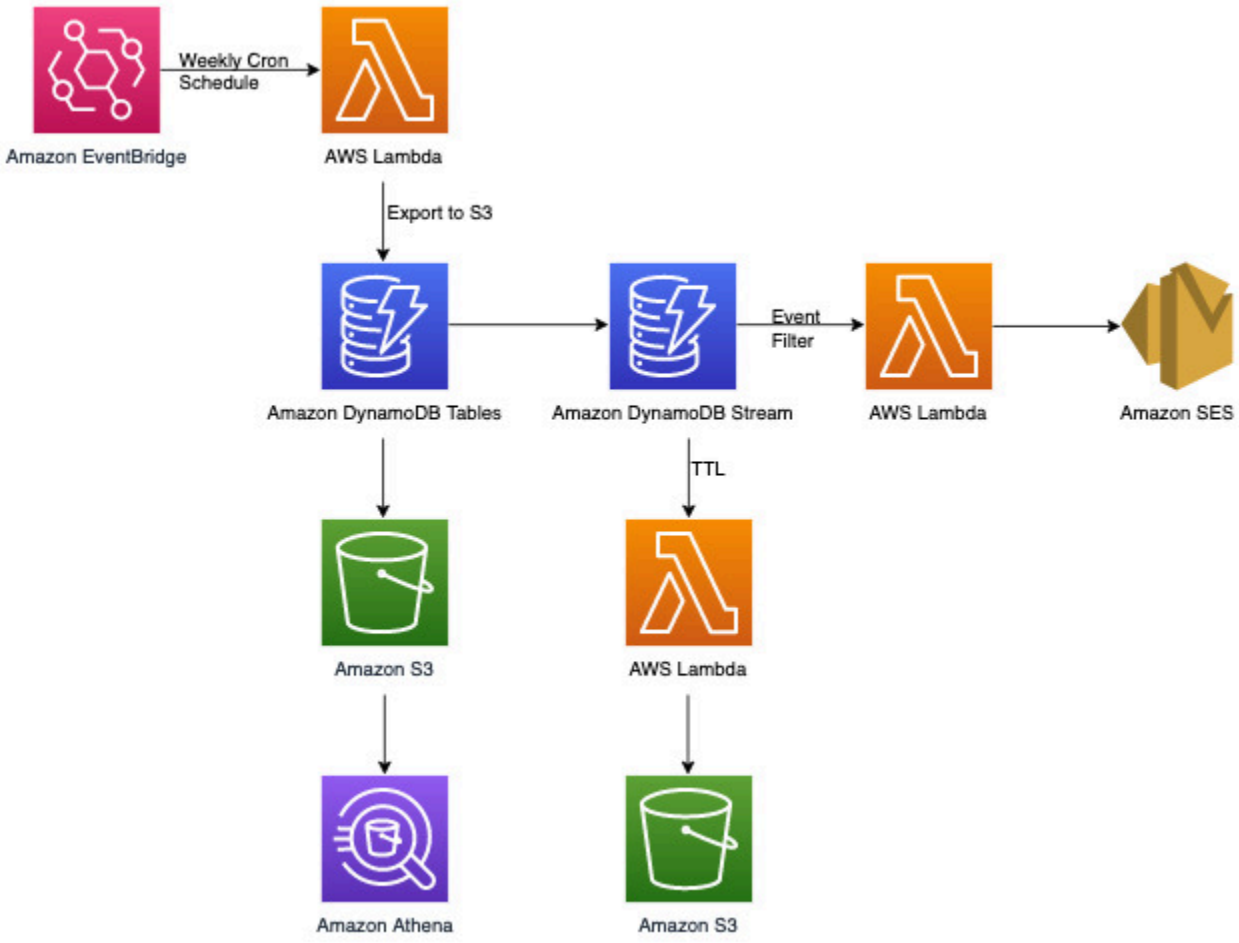
DynamoDB is a database well-suited for a complaint management system (or contact center) use case as most access patterns associated with them would be key-value based transactional lookups. The typical access patterns in this scenario would be to:

- Create and update complaints
- Escalate a complaint
- Create and read comments on a complaint
- Get all complaints by a customer
- Get all comments by an agent and get all escalations

Some comments may have attachments describing the complaint or solution. While these are all key-value access patterns, there can be additional requirements such as sending out notifications when a new comment is added to a complaint or running analytical queries to find complaint distribution by severity (or agent performance) per week. An additional requirement related to lifecycle management or compliance would be to archive complaint data after three years of logging the complaint.

Complaint management system architecture diagram

The following diagram shows the architecture diagram of the complaint management system. This diagram shows the different AWS service integrations that the complaint management system uses.



Apart from the key-value transactional access patterns that we will be handling in the DynamoDB data modeling section later, we have three non-transactional requirements. The architecture diagram above can be broken down into the following three workflows:

1. Send a notification when a new comment is added to a complaint
2. Run analytical queries on weekly data
3. Archive data older than three years

Let's take a more in-depth look at each one.

Send a notification when a new comment is added to a complaint

We can use the below workflow to achieve this requirement:

DynamoDB Streams is a change data capture mechanism to record all write activity on your DynamoDB tables. You can configure Lambda functions to trigger on some or all of these changes. An event filter can be configured on Lambda triggers to filter out events that are not relevant to the use-case. In this instance, we can use a filter to trigger Lambda only when a new comment is added and send out notification to relevant email ID(s) which can be fetched from AWS Secrets Manager or any other credential store.

Run analytical queries on weekly data

DynamoDB is suitable for workloads that are primarily focused on online transactional processing (OLTP). For the other 10-20% access patterns with analytical requirements, data can be exported to S3 with the managed Export to Amazon S3 feature with no impact to the live traffic on DynamoDB table. Take a look at this workflow below:

Amazon EventBridge can be used to trigger AWS Lambda on schedule - it allows you to configure a cron expression for Lambda invocation to take place periodically. Lambda can invoke the `ExportToS3` API call and store DynamoDB data in S3. This S3 data can then be accessed by a SQL

engine such as Amazon Athena to run analytical queries on DynamoDB data without affecting the live transactional workload on the table. A sample Athena query to find number of complaints per severity level would look like this:

```
SELECT Item.severity.S as "Severity", COUNT(Item) as "Count"
FROM "complaint_management"."data"
WHERE NOT Item.severity.S = ''
GROUP BY Item.severity.S ;
```

This results in the following Athena query result:

Results (3)

Search rows

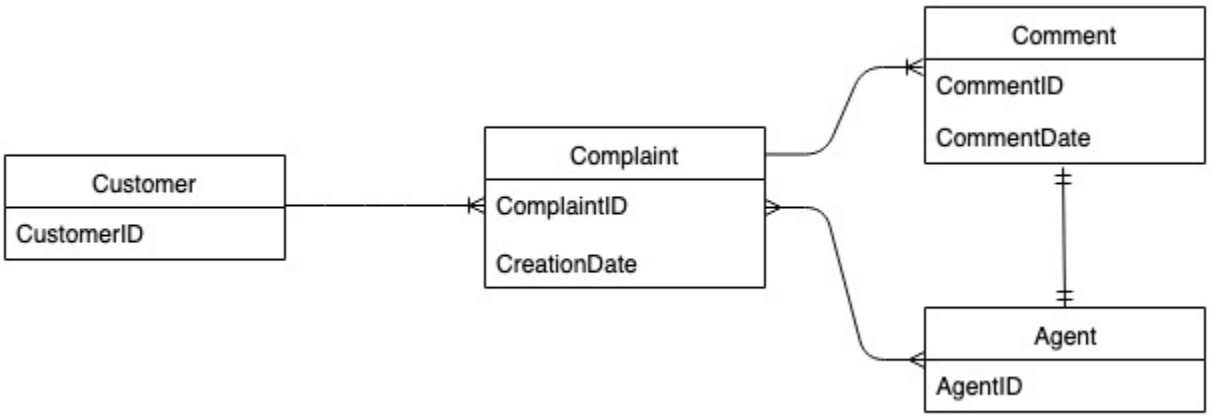
#	Severity	Count
1	P3	1
2	P2	2
3	P1	1

Archive data older than three years

You can leverage the DynamoDB Time to Live (TTL) feature to delete obsolete data from your DynamoDB table at no additional cost (except in the case of global tables replicas for the 2019.11.21 (Current) version, where TTL deletes replicated to other Regions consume write capacity). This data appears and can be consumed from DynamoDB Streams to be archived off into Amazon S3. The workflow for this requirement is as follows:

Complaint management system entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the complaint management system schema design.



Complaint management system access patterns

These are the access patterns we'll be considering for the complaint management schema design.

1. createComplaint
2. updateComplaint
3. updateSeveritybyComplaintID
4. getComplaintByComplaintID
5. addCommentByComplaintID
6. getAllCommentsByComplaintID

13. getCommentsByAgentID (between two dates)

Complaint management system schema design evolution

Since this is a complaint management system, most access patterns revolve around a complaint as the primary entity. The `ComplaintID` being highly cardinal will ensure even distribution of data

in the underlying partitions and is also the most common search criteria for our identified access patterns. Therefore, `ComplaintID` is a good partition key candidate in this data set.

Step 1: Address access patterns 1 (`createComplaint`), 2 (`updateComplaint`), 3 (`updateSeveritybyComplaintID`), and 4 (`getComplaintByComplaintID`)

We can use a generic sort key valued called "metadata" (or "AA") to store complaint-specific information such as `CustomerID`, `State`, `Severity`, and `CreationDate`. We use singleton operations with `PK=ComplaintID` and `SK="metadata"` to do the following:

1. `PutItem` to create a new complaint
2. `UpdateItem` to update the severity or other fields in the complaint metadata
3. `GetItem` to fetch metadata for the complaint

Primary key		Attributes				
Partition key: PK	Sort key: SK					
Complaint1321	metadata	customer_id	current_state	creation_time	severity	complaint_description
		custXYZ	assigned	2023-05-10T15:58:00	P2	<Complaint Description>

Step 2: Address access pattern 5 (`addCommentByComplaintID`)

This access pattern requires a one-to-many relationship model between a complaint and comments on the complaint. We will use the vertical partitioning technique here to use a sort key and create an item collection with different types of data. If we look at access patterns 6 (`getAllCommentsByComplaintID`) and 7 (`getLatestCommentByComplaintID`), we know that comments will need to be sorted by time. We can also have multiple comments coming in at the same time so we can use the composite sort key technique to append time and `CommentID` in the sort key attribute.

Other options to deal with such possible comment collisions would be to increase the granularity for the timestamp or add an incremental number as a suffix instead of using `Comment_ID`. In this case, we'll prefix the sort key value for items corresponding to comments with "comm#" to enable range-based operations.

We also need to make sure that the `currentState` in the complaint metadata reflects the state when a new comment is added. Adding a comment might indicate that the complaint has been assigned to an agent or it has been resolved and so on. In order to bundle the addition of comment

and update of current state in the complaint metadata, in an all-or-nothing manner, we will use the TransactWriteItems API. The resulting table state now looks like this:

Primary key		Attributes				
Partition key: PK	**Sort key: SK**					
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm_id	comm_date	complaint_state	comm_text	agentID
		comm3	2023-05-10T16:00:00	investigating	<Comment text>	AgentB
	metadata	customer_id	current_state	creation_time	severity	complaint_description
		custXYZ	investigating	2023-05-10T15:58:00	P2	<Complaint Description>

Let's add some more data in the table and also add `ComplaintID` as a separate field from our PK for future-proofing the model in case we need additional indexes on `ComplaintID`. Also note that some comments may have attachments which we will store in Amazon Simple Storage Service and only maintain their references or URLs in DynamoDB. It's a best practice to keep the transactional database as lean as possible to optimize cost and performance. The data now looks like this:

Primary key		Attributes					
Partition key: PK	**Sort key: SK**						
Complaint123	comm#2023-04-30T12:00:24#comm1	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA	
	comm#2023-04-30T12:35:54#comm2	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]	AgentA
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custABC	Complaint123	resolved	2023-04-30T12:00:00	P2	<description text>
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB	
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>

Step 3: Address access patterns 6 (`getAllCommentsByComplaintID`) and 7 (`getLatestCommentByComplaintID`)

In order to get all comments for a complaint, we can use the `query` operation with the `begins_with` condition on the sort key. Instead of consuming additional read capacity to read

the metadata entry and then having the overhead of filtering the relevant results, having a sort key condition like this help us only read what we need. For example, a query operation with PK=Complaint123 and SK begins_with comm# would return the following while skipping the metadata entry:

Primary key		Attributes					
Partition key: PK	Sort key: SK						
Complaint123	comm#2023-04-30T12:00:24#comm1	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA	
	comm#2023-04-30T12:35:54#comm2	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]	AgentA
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custABC	Complaint123	resolved	2023-04-30T12:00:00	P2	<description text>
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB	
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>

Since we need the latest comment for a complaint in pattern 7 (`getLatestCommentByComplaintID`), let's use two additional query parameters:

1. `ScanIndexForward` should be set to False to get results sorted in a descending order
2. `Limit` should be set to 1 to get the latest (only one) comment

Similar to access pattern 6 (`getAllCommentsByComplaintID`), we skip the metadata entry using `begins_with comm#` as the sort key condition. Now, you can perform access pattern 7 on this design using the query operation with `PK=Complaint123` and `SK=begins_with comm#`, `ScanIndexForward=False`, and `Limit` 1. The following targeted item will be returned as a result:

Partition key: PK	Sort key: SK	Attributes					
	comm#2023-04-30T12:00:24#comm1	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA	
Complaint123	comm#2023-04-30T12:35:54#comm2	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]	AgentA
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custABC	Complaint123	resolved	2023-04-30T12:00:00	P2	<description text>
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB	
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>

Let's add more dummy data to the table.

Primary key		Attributes					
Partition key: PK	**Sort key: SK**						
Complaint123	comm#2023-04-30T12:00:24#comm1	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA	
	comm#2023-04-30T12:35:54#comm2	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]	AgentA
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custABC	Complaint123	resolved	2023-04-30T12:00:00	P2	<description text>
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB	
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>
Complaint1444	comm#2022-12-31T19:32:00#comm4	comm_id	comm_date	complaint_state	comm_text		
		comm4	2022-12-31T19:32:00	waiting	<comm text>		
	comm#2022-12-31T19:40:00#comm5	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm5	2022-12-31T19:40:00	assigned	<comm text>	["s3://URL_for_attachment1"]	AgentC
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXY32	Complaint1444	assigned	2022-12-31T19:39:57	P1	<description text>
Complaint0987	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint0987	assigned	2023-06-10T12:30:08	P3	<description text>

Step 4: Address access patterns 8 (`getAComplaintbyCustomerIDAndComplaintID`) and 9 (`getAllComplaintsByCustomerID`)

Access patterns 8 (`getAComplaintbyCustomerIDAndComplaintID`) and 9 (`getAllComplaintsByCustomerID`) introduces a new search criteria: `CustomerID`. Fetching it from the existing table requires an expensive Scan to read all data and then filter relevant items for the `CustomerID` in question. We can make this search more efficient by creating

a global secondary index (GSI) with `CustomerID` as the partition key. Keeping in mind the one-to-many relationship between customer and complaints as well as access pattern 9 (`getAllComplaintsByCustomerID`), `ComplaintID` would be the right candidate for the sort key.

The data in the GSI would look like this:

Primary key		Attributes					
Partition key: customer_id	**Sort key: complaint_id**						
custABC	Complaint123	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint123	metadata	resolved	2023-04-30T12:00:00	P2	<description text>
custXY32	Complaint1444	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1444	metadata	assigned	2022-12-31T19:39:57	P1	<description text>
custXYZ	Complaint0987	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint0987	metadata	assigned	2023-06-10T12:30:08	P3	<description text>
	Complaint1321	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1321	metadata	investigating	2023-05-10T15:58:00	P2	<descr_text>

An example query on this GSI for access pattern 8 (`getAComplaintbyCustomerIDAndComplaintID`) would be: `customer_id=custXYZ`, `sort key=Complaint1321`. The result would be:

Primary key		Attributes					
Partition key: customer_id	**Sort key: complaint_id**						
custABC	Complaint123	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint123	metadata	resolved	2023-04-30T12:00:00	P2	<description text>
custXY32	Complaint1444	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1444	metadata	assigned	2022-12-31T19:39:57	P1	<description text>
	Complaint0987	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint0987	metadata	assigned	2023-06-10T12:30:08	P3	<description text>
custXYZ							
	Complaint1321	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1321	metadata	investigating	2023-05-10T15:58:00	P2	<descr_text>

To get all complaints for a customer for access pattern 9 (`getAllComplaintsByCustomerID`), the query on the GSI would be: `customer_id=custXYZ` as the partition key condition. The result would be:

Primary key		Attributes					
Partition key: customer_id	**Sort key: complaint_id**						
custABC	Complaint123	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint123	metadata	resolved	2023-04-30T12:00:00	P2	<description text>
custXY32	Complaint1444	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1444	metadata	assigned	2022-12-31T19:39:57	P1	<description text>
custXYZ	Complaint0987	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint0987	metadata	assigned	2023-06-10T12:30:08	P3	<description text>
	Complaint1321	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1321	metadata	investigating	2023-05-10T15:58:00	P2	<descr_text>

Step 5: Address access pattern 10 (`escalateComplaintByComplaintID`)

This access introduces the escalation aspect. To escalate a complaint, we can use `UpdateItem` to add attributes such as `escalated_to` and `escalation_time` to the existing complaint metadata item. DynamoDB provides flexible schema design which means a set of non-key attributes can be uniform or discrete across different items. See below for an example:

`UpdateItem with PK=Complaint1444, SK=metadata`

Complaint1444	comm#2022-12-31T19:32:00#comm4	comm_id	comm_date	complaint_state	comm_text			
		comm4	2022-12-31T19:32:00	waiting	<comm text>			
	comm#2022-12-31T19:40:00#comm5	comm_id	comm_date	complaint_state	comm_text	attachments	agentID	
		comm5	2022-12-31T19:40:00	assigned	<comm text>	["s3://URL_for_attachment1"]	AgentC	
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description	escalated_to	escalation_time
		custXY32	Complaint1444	assigned	2022-12-31T19:39:57	P1	<description text>	AgentB	2023-01-03T04:00:07

Step 6: Address access patterns 11 (`getAllEscalatedComplaints`) and 12 (`getEscalatedComplaintsByAgentID`)

Only a handful of complaints are expected to be escalated out of the whole data set. Therefore, creating an index on the escalation-related attributes would lead to efficient lookups as well as

cost-effective GSI storage. We can do this by leveraging the sparse index technique. The GSI with partition key as `escalated_to` and sort key as `escalation_time` would look like this:

Primary key		Attributes							
Partition key: escalated_to	**Sort key: escalation_time**								
AgentB	2023-01-03T04:00:07	PK	SK	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		Complaint1444	metadata	custXY32	Complaint1444	assigned	2022-12-31T19:39:57	P1	<description text>
	2023-05-15T14:00:00	PK	SK	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		Complaint1321	metadata	custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>

To get all escalated complaints for access pattern 11 (`getAllEscalatedComplaints`), we simply scan this GSI. Note that this scan will be performant and cost-efficient due to the size of the GSI. To get escalated complaints for a specific agent (access pattern 12 (`getEscalatedComplaintsByAgentID`)), the partition key would be `escalated_to=agentID` and we set `ScanIndexForward` to `False` for ordering from newest to oldest.

Step 7: Address access pattern 13 (`getCommentsByAgentID`)

For the last access pattern, we need to perform a lookup by a new dimension: `AgentID`. We also need time-based ordering to read comments between two dates so we create a GSI with `agent_id` as the partition key and `comm_date` as the sort key. The data in this GSI will look like the following:

Primary key		Attributes					
Partition key: agentID	**Sort key: comm_date**						
AgentA	2023-04-30T12:00:24	PK	SK	comm_id	complaint_state	comm_text	
		Complaint123	comm#2023-04-30T12:00:24#comm1	comm1	investigating	<comm text>	
	2023-04-30T12:35:54	PK	SK	comm_id	complaint_state	comm_text	attachments
		Complaint123	comm#2023-04-30T12:35:54#comm2	comm2	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]
AgentB	2023-05-10T16:00:00	PK	SK	comm_id	complaint_state	comm_text	
		Complaint1321	comm#2023-05-10T16:00:00#comm3	comm3	investigating	<comm text>	
AgentC	2022-12-31T19:40:00	PK	SK	comm_id	complaint_state	comm_text	attachments
		Complaint1444	comm#2022-12-31T19:40:00#comm5	comm5	assigned	<comm text>	["s3://URL_for_attachment1"]

An example query on this GSI would be `partition key agentID=AgentA and sort key=comm_date between (2023-04-30T12:30:00, 2023-05-01T09:00:00)`, the result of which is:

Primary key		Attributes					
Partition key: agentID	Sort key: comm_date						
AgentA	2023-04-30T12:00:24	PK	SK	comm_id	complaint_state	comm_text	
		Complaint123	comm#2023-04-30T12:00:24#comm1	comm1	investigating	<comm text>	
	2023-04-30T12:35:54	PK	SK	comm_id	complaint_state	comm_text	attachments
		Complaint123	comm#2023-04-30T12:35:54#comm2	comm2	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]
AgentB	2023-05-10T16:00:00	PK	SK	comm_id	complaint_state	comm_text	
		Complaint1321	comm#2023-05-10T16:00:00#comm3	comm3	investigating	<comm text>	
AgentC	2022-12-31T19:40:00	PK	SK	comm_id	complaint_state	comm_text	attachments
		Complaint1444	comm#2022-12-31T19:40:00#comm5	comm5	assigned	<comm text>	["s3://URL_for_attachment1"]

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
createComplaint	Base table	PutItem	PK=complaint_id	SK=metadata	
updateComplaint	Base table	UpdateItem	PK=complaint_id	SK=metadata	
updateSeveritybyComplaintID	Base table	UpdateItem	PK=complaint_id	SK=metadata	
getComplaintByComplaintID	Base table	GetItem	PK=complaint_id	SK=metadata	
addCommentByComplaintID	Base table	TransactWriteItems	PK=complaint_id	SK=metadata, SK=comm#comm_date#comm_id	

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getAllCommentsByComplaintID	Base table	Query	PK=complaint_id	SK begins_with "comm#"	
getLatestCommentByComplaintID	Base table	Query	PK=complaint_id	SK begins_with "comm#"	scan_index_forward =False, Limit 1
getAComplaintbyCustomerIDAndComplaintID	Customer_complaint_GSI	Query	customer_id=customer_id	complaint_id = complaint_id	
getAllComplaintsByCustomerID	Customer_complaint_GSI	Query	customer_id=customer_id	N/A	
escalateComplaintByComplaintID	Base table	UpdateItem	PK=complaint_id	SK=metadata	
getAllEscalatedComplaints	Escalations_GSI	Scan	N/A	N/A	
getEscalatedComplaintsByAgentID (order from newest to oldest)	Escalations_GSI	Query	escalated_to=agent_id	N/A	scan_index_forward =False

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getCommentsByAgentID (between two dates)	Agents_Comments_GSI	Query	agent_id= agent_id	SK between (date1, date2)	

Complaint management system final schema

Here are the final schema designs. To download this schema design as a JSON file, see DynamoDB Examples on GitHub.

Base table

Primary key		Attributes

Using NoSQL Workbench with this schema design

You can import this final schema into NoSQL Workbench, a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see the section called “Download”.
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see the section called “Importing an existing model”.
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see the section called “Editing an existing model”.

Recurring payments schema design in DynamoDB

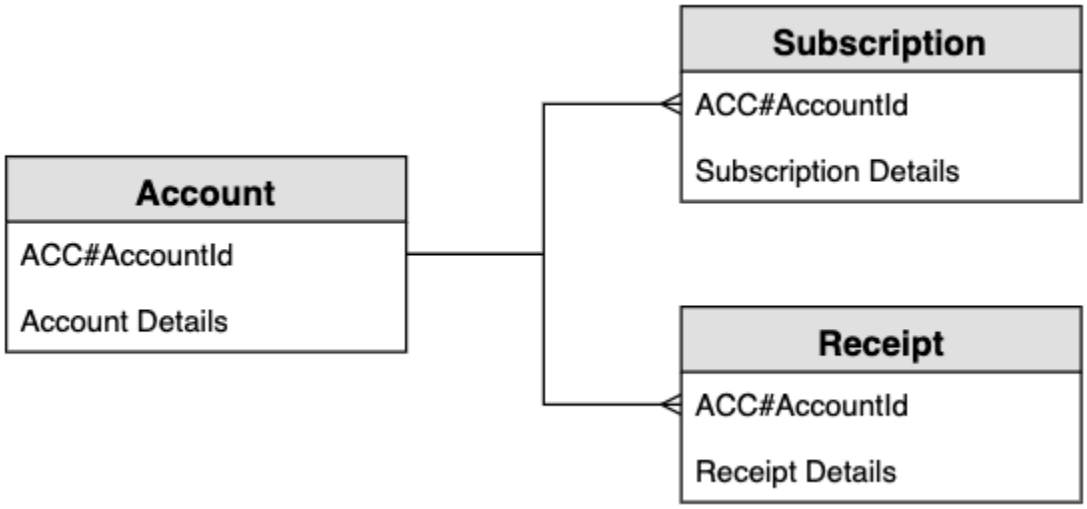
Recurring payments business use case

This use case talks about using DynamoDB to implement a recurring payments system. The data model has the following entities: *accounts*, *subscriptions*, and *receipts*. The specifics for our use case include the following:

- Each *account* can have multiple *subscriptions*
- The *subscription* has a `NextPaymentDate` when the next payment needs to be processed and a `NextReminderDate` when an email reminder is sent to the customer
- There is an item for the *subscription* that is stored and updated when the payment been processed (the average item size is around 1KB and the throughput depends on the number of *accounts* and *subscriptions*)
- The *payment* processor will also create a *receipt* as part of the process which is stored in the table and are set to expire after a period of time by using a TTL attribute

Recurring payments entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the recurring payments system schema design.



Recurring payments system access patterns

These are the access patterns we'll be considering for the recurring payments system schema design.

1. `createSubscription`
2. `createReceipt`
3. `updateSubscription`
4. `getDueRemindersByDate`
5. `getDuePaymentsByDate`
6. `getSubscriptionsByAccount`
7. `getReceiptsByAccount`

Recurring payments schema design

The generic names PK and SK are used for key attributes to allow storing different types of entities in the same table such as the account, subscription, and receipt entities. The user first creates a subscription, which is where the user agrees to pay an amount on the same day each month in return for a product. They get the choice on which day of the month to process the payment. There is also a reminder that will be sent prior to the payment being processed. The application works by having two batch jobs that run each day: one batch job sends reminders due that day and the other batch job processes any payments due that day.

Step 1: Address access pattern 1 (`createSubscription`)

Access pattern 1 (`createSubscription`) is used to initially create the subscription, and the details including SKU, `NextPaymentDate`, `NextReminderDate` and `PaymentDetails` are set. This step shows the state of the table for just one account with one subscription. There can be multiple subscriptions in the item collection so this is a one-to-many relationship.

Primary key		Attributes									
Partition key: PK	**Sort key: SK**										
		Email	PaymentDay	PaymentAmount	LastPaymentDate	NextPaymentDate	LastReminderDate	NextReminderDate	SKU	PaymentDetails	CreatedDate
ACC#123	SUB#123#SKU#999	s@s.com	28	12.99	1970-01-01T00:00:00.000Z	2023-05-28	1970-01-01T00:00:00.000Z	2023-05-21	999	{"default-card":{"S":"1234123412341234"},"default-address":{"S":"12 Bridge Street, Birmingham, B12 7ST"}}	2023-05-18T09:41:25.856Z

Step 2: Address access patterns 2 (`createReceipt`) and 3 (`updateSubscription`)

Access pattern 2 (`createReceipt`) is used to create the receipt item. After the payment is processed each month, the payment processor will write a receipt back to the base table. There, could be multiple receipts in the item collection so this is a one-to-many relationship. The payment processor will also update the subscription item (access Pattern 3 (`updateSubscription`)) to update for the `NextReminderDate` or the `NextPaymentDate` for the next month.

Primary key		Attributes									
Partition key: PK	**Sort key: SK**										
ACC#123	REC#12023-05-28T14:15:39.24#SKU#999	Email	SKU	ProcessedDate	ProcessedAmount	TTL					
		s@s.com	999	2023-05-28T14:15:39.247Z	12.99	1700318200					
	SUB#123#SKU#999	Email	PaymentDay	PaymentAmount	LastPaymentDate	NextPaymentDate	LastReminderDate	NextReminderDate	SKU	PaymentDetails	CreatedDate
		s@s.com	28	12.99	2023-05-18T14:15:39.247Z	2023-06-28	2023-05-21T14:15:39.247Z	2023-06-21	999	{"default-card":{"S":"1234123412341234"},"default-address":{"S":"12 Bridge Street, Birmingham, B12 7ST"}}	2023-05-18T09:41:25.856Z

Step 3: Address access pattern 4 (`getDueRemindersByDate`)

The application processes reminders for the payment in batches for the current day. Therefore the application needs to access the subscriptions on a different dimension: date rather than account. This is a good use case for a global secondary index (GSI). In this step we add the index `GSI-1`, which uses the `NextReminderDate` as the GSI partition key. We do not need to replicate all the items. This GSI is a sparse index and the receipts items are not replicated. We also do not need to project all the attributes—we only need to include a subset of the attributes. The image below shows the schema of `GSI-1` and it gives the information needed for the application to send the reminder email.

Primary key		Attributes				
Partition key: NextReminderDate	**Sort key: LastReminderDate**					
		SK	PK	SKU	Email	NextPaymentDate
2023-06-21	2023-05-21T14:15:39.247Z	SUB#123#SKU#999	ACC#123	999	s@s.com	2023-06-28

Step 4: Address access pattern 5 (`getDuePaymentsByDate`)

The application processes the payments in batches for the current day in the same way it does with reminders. We add `GSI-2` in this step, and it uses the `NextPaymentDate` as the GSI partition key. We do not need to replicate all the items. This GSI is a sparse index as the receipts items are not replicated. The image below shows the schema of `GSI-2`.

Primary key		Attributes						
Partition key: NextPaymentDate	Sort key: LastPaymentDate	PK	SK	Email	PaymentDay	PaymentAmount	SKU	PaymentDetails
2023-06-28	2023-05-18T14:15:39.247Z	ACC#123	SUB#123#SKU#999	s@s.com	28	12.99	999	{"default-card":{"S":"1234123412341234"},"default-address":{"S":"12 Bridge Street, Birmingham, B12 7ST"}}

Step 5: Address access patterns 6 (`getSubscriptionsByAccount`) and 7 (`getReceiptsByAccount`)

The application can retrieve all the subscriptions for an account by using a query on the base table that targets the account identifier (the PK) and uses the range operator to get all the items where the SK begins with "SUB#". The application can also use the same query structure to retrieve all the receipts by using a range operator to get all the items where the SK begins with "REC#". This allows us to satisfy access patterns 6 (`getSubscriptionsByAccount`) and 7 (`getReceiptsByAccount`). The application uses these access patterns so the user can see their current subscriptions and their past receipts for the last six months. There is no change to the table schema in this step and we can see below how we target just the subscription item(s) in access pattern 6 (`getSubscriptionsByAccount`).

Primary key		Attributes									
Partition key: PK	Sort key: SK										
	REC#12023-05-28T14:15:39.24#SKU#999	Email	SKU	ProcessedDate	ProcessedAmount	TTL					
		s@s.com	999	2023-05-28T14:15:39.247Z	12.99	1700318200					
ACC#123	SUB#123#SKU#999	Email	PaymentDay	PaymentAmount	LastPaymentDate	NextPaymentDate	LastReminderDate	NextReminderDate	SKU	PaymentDetails	CreatedDate
		s@s.com	28	12.99	2023-05-18T14:15:39.247Z	2023-06-28	2023-05-21T14:15:39.247Z	2023-06-21	999	{"default-card":{"S":"1234123412341234"},"default-address":{"S":"12 Bridge Street, Birmingham, B12 7ST"}}	2023-05-18T09:41:25.856Z

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/GSI/LSI	Operation	Partition key value	Sort key value
createSubscription	Base table	PutItem	ACC#account_id	SUB#<SUBID>#SKU<SKUID>

Access pattern	Base table/GSI/LSI	Operation	Partition key value	Sort key value
createReceipt	Base table	PutItem	ACC#account_id	REC#<ReceiptDate>#SKU<SKUID>
updateSubscription	Base table	UpdateItem	ACC#account_id	SUB#<SUBID>#SKU<SKUID>
getDueRemindersByDate	GSI-1	Query	<NextReminderDate>	
getDuePaymentsByDate	GSI-2	Query	<NextPaymentDate>	
getSubscriptionsByAccount	Base table	Query	ACC#account_id	SK begins_with “SUB#”
getReceiptsByAccount	Base table	Query	ACC#account_id	SK begins_with “REC#”

Recurring payments final schema

Here are the final schema designs. To download this schema design as a JSON file, see DynamoDB Examples on GitHub.

Using NoSQL Workbench with this schema design

You can import this final schema into NoSQL Workbench, a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see the section called “Download”.
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see the section called “Importing an existing model”.
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see the section called “Editing an existing model”.

Monitoring device status updates in DynamoDB

This use case talks about using DynamoDB to monitor device status updates (or changes in device state) in DynamoDB.

Use case

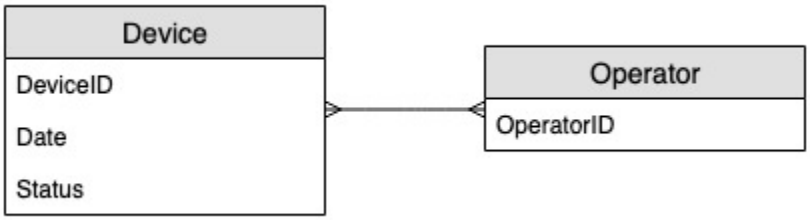
In IoT use-cases (a smart factory for instance) many devices need to be monitored by operators and they periodically send their status or logs to a monitoring system. When there is a problem with a device, the status for the device changes from *normal* to *warning*. There are different log levels or statuses depending on the severity and type of abnormal behavior in the device. The system then assigns an operator to check on the device and they may escalate the problem to their supervisor if needed.

Some typical access patterns for this system include:

- Create log entry for a device
- Get all logs for a specific device state showing the most recent logs first
- Get all logs for a given operator between two dates
- Get all escalated logs for a given supervisor
- Get all escalated logs with a specific device state for a given supervisor
- Get all escalated logs with a specific device state for a given supervisor for a specific date

Entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for monitoring device status updates.



Access patterns

These are the access patterns we'll be considering for monitoring device status updates.

1. `createLogEntryForSpecificDevice`
2. `getLogsForSpecificDevice`
3. `getWarningLogsForSpecificDevice`
4. `getLogsForOperatorBetweenTwoDates`
5. `getEscalatedLogsForSupervisor`
6. `getEscalatedLogsWithSpecificStatusForSupervisor`
7. `getEscalatedLogsWithSpecificStatusForSupervisorForDate`

Schema design evolution

Step 1: Address access patterns 1 (`createLogEntryForSpecificDevice`) and 2 (`getLogsForSpecificDevice`)

The unit of scaling for a device tracking system would be individual devices. In this system, a `deviceID` uniquely identifies a device. This makes `deviceID` a good candidate for the partition key. Each device sends information to the tracking system periodically (say, every five minutes or so). This ordering makes date a logical sorting criterion and therefore, the sort key. The sample data in this case would look something like this:

Primary key		Attributes
Partition key: DeviceID	Sort key: State#Date	
d#12345	2020-04-24T14:40:00	State
		WARNING1
	2020-04-24T14:45:00	State
		WARNING1
	2020-04-24T14:50:00	State
		WARNING1
	2020-04-24T14:55:00	State
		NORMAL
d#54321	2020-04-11T05:50:00	State
		WARNING3
	2020-04-11T05:55:00	State
		WARNING3
	2020-04-11T06:00:00	State
		NORMAL
	2020-04-11T09:25:00	State
		WARNING2
	2020-04-11T09:30:00	State
		NORMAL
d#11223	2020-04-27T16:10:00	State
		WARNING4
	2020-04-27T16:15:00	State
		WARNING4

To fetch log entries for a specific device, we can perform a query operation with partition key `DeviceID="d#12345"`.

Step 2: Address access pattern 3 (`getWarningLogsForSpecificDevice`)

Since `State` is a non-key attribute, addressing access pattern 3 with the current schema would require a filter expression. In DynamoDB, filter expressions are applied after data is read using

key condition expressions. For example, if we were to fetch warning logs for d#12345, the query operation with partition key `DeviceID="d#12345"` will read four items from the above table and then filter out the one item without the *warning* status. This approach is not efficient at scale. A filter expression can be a good way to exclude items that are queried if the ratio of excluded items is low or the query is performed infrequently. However, for cases where many items are retrieved from a table and the majority of the items are filtered out, we can continue evolving our table design so it runs more efficiently.

Let's change how to handle this access pattern by using composite sort keys. You can import sample data from DeviceStateLog_3.json where the sort key is changed to `State#Date`. This sort key is the composition of the attributes `State`, `#`, and `Date`. In this example, # is used as a delimiter. The data now looks something like this:

Primary key	
Partition key: DeviceID	**Sort key: State#Date**
d#12345	NORMAL#2020-04-24T14:55:00
	WARNING1#2020-04-24T14:40:00
	WARNING1#2020-04-24T14:45:00
	WARNING1#2020-04-24T14:50:00

To fetch only warning logs for a device, the query becomes more targeted with this schema. The key condition for the query uses partition key `DeviceID="d#12345"` and sort key `State#Date begins_with "WARNING"`. This query will only read the relevant three items with the *warning* state.

Step 3: Address access pattern 4 (`getLogsForOperatorBetweenTwoDates`)

You can import DeviceStateLog_4.jsonD where the `Operator` attribute was added to the `DeviceStateLog` table with example data.

Primary key		Attributes		
Partition key: DeviceID	**Sort key: State#Date**			
d#12345	NORMAL#2020-04-24T14:55:00	Operator	Date	State
		Liz	2020-04-24T14:55:00	NORMAL
	WARNING1#2020-04-24T14:40:00	Operator	Date	State
		Liz	2020-04-24T14:40:00	WARNING1
	WARNING1#2020-04-24T14:45:00	Operator	Date	State
		Liz	2020-04-24T14:45:00	WARNING1
	WARNING1#2020-04-24T14:50:00	Operator	Date	State
		Liz	2020-04-24T14:50:00	WARNING1
d#54321	NORMAL#2020-04-11T06:00:00	Operator	Date	State
		Liz	2020-04-11T06:00:00	NORMAL
	NORMAL#2020-04-11T09:30:00	Operator	Date	State
		Sue	2020-04-11T09:30:00	NORMAL
	WARNING2#2020-04-11T09:25:00	Operator	Date	State
		Sue	2020-04-11T09:25:00	WARNING2
	WARNING3#2020-04-11T05:50:00	Operator	Date	State
		Sue	2020-04-11T05:50:00	WARNING3
	WARNING3#2020-04-11T05:55:00	Operator	Date	State
		Liz	2020-04-11T05:55:00	WARNING3
d#11223	WARNING4#2020-04-27T16:10:00	Operator	Date	State
		Sue	2020-04-27T16:10:00	WARNING4
	WARNING4#2020-04-27T16:15:00	Operator	Date	State
		Sue	2020-04-27T16:15:00	WARNING4

Since `Operator` is not currently a partition key, there is no way to perform a direct key-value lookup on this table based on `OperatorID`. We'll need to create a new item collection with a

global secondary index on `OperatorID`. The access pattern requires a lookup based on dates so Date is the sort key attribute for the global secondary index (GSI). This is what the GSI now looks like:

Primary key		Attributes		
Partition key: Operator	**Sort key: Date**			
Liz	2020-04-11T05:55:00	DeviceID	State#Date	State
		d#54321	WARNING3#2020-04-11T05:55:00	WARNING3
	2020-04-11T06:00:00	DeviceID	State#Date	State
		d#54321	NORMAL#2020-04-11T06:00:00	NORMAL
	2020-04-24T14:40:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:40:00	WARNING1
	2020-04-24T14:45:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:45:00	WARNING1
	2020-04-24T14:50:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:50:00	WARNING1
	2020-04-24T14:55:00	DeviceID	State#Date	State
		d#12345	NORMAL#2020-04-24T14:55:00	NORMAL
Sue	2020-04-11T05:50:00	DeviceID	State#Date	State
		d#54321	WARNING3#2020-04-11T05:50:00	WARNING3
	2020-04-11T09:25:00	DeviceID	State#Date	State
		d#54321	WARNING2#2020-04-11T09:25:00	WARNING2
	2020-04-11T09:30:00	DeviceID	State#Date	State
		d#54321	NORMAL#2020-04-11T09:30:00	NORMAL
	2020-04-27T16:10:00	DeviceID	State#Date	State
		d#11223	WARNING4#2020-04-27T16:10:00	WARNING4
	2020-04-27T16:15:00	DeviceID	State#Date	State
		d#11223	WARNING4#2020-04-27T16:15:00	WARNING4

For access pattern 4 (`getLogsForOperatorBetweenTwoDates`), you can query this GSI with partition key `OperatorID=Liz` and sort key `Date` between `2020-04-11T05:58:00` and `2020-04-24T14:50:00`.

Primary key		Attributes		
Partition key: Operator	**Sort key: Date**			
	2020-04-11T05:55:00	DeviceID	State#Date	State
		d#54321	WARNING3#2020-04-11T05:55:00	WARNING3
Liz	2020-04-11T06:00:00	DeviceID	State#Date	State
		d#54321	NORMAL#2020-04-11T06:00:00	NORMAL
	2020-04-24T14:40:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:40:00	WARNING1
	2020-04-24T14:45:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:45:00	WARNING1

		d#11223	WARNING4#2020-04-27T16:15:00	WARNING4

Step 4: Address access patterns 5 (`getEscalatedLogsForSupervisor`) 6 (`getEscalatedLogsWithSpecificStatusForSupervisor`), and 7 (`getEscalatedLogsWithSpecificStatusForSupervisorForDate`)

We'll be using a sparse index to address these access patterns.

Global secondary indexes are sparse by default, so only items in the base table that contain primary key attributes of the index will actually appear in the index. This is another way of excluding items that are not relevant for the access pattern being modeled.

You can import DeviceStateLog_6.json where the `EscalatedTo` attribute was added to the `DeviceStateLog` table with example data. As mentioned earlier, not all of the logs gets escalated to a supervisor.

Primary key		Attributes			
Partition key: DeviceID	**Sort key: State#Date**				
d#12345	NORMAL#2020-04-24T14:55:00	Operator	Date	State	
		Liz	2020-04-24T14:55:00	NORMAL	
	WARNING1#2020-04-24T14:40:00	Operator	Date	State	
		Liz	2020-04-24T14:40:00	WARNING1	
	WARNING1#2020-04-24T14:45:00	Operator	Date	State	
		Liz	2020-04-24T14:45:00	WARNING1	
	WARNING1#2020-04-24T14:50:00	Operator	Date	State	
		Liz	2020-04-24T14:50:00	WARNING1	
d#54321	NORMAL#2020-04-11T06:00:00	Operator	Date	State	
		Liz	2020-04-11T06:00:00	NORMAL	
	NORMAL#2020-04-11T09:30:00	Operator	Date	State	
		Sue	2020-04-11T09:30:00	NORMAL	
	WARNING2#2020-04-11T09:25:00	Operator	Date	State	
		Sue	2020-04-11T09:25:00	WARNING2	
	WARNING3#2020-04-11T05:50:00	Operator	Date	State	
		Sue	2020-04-11T05:50:00	WARNING3	
	WARNING3#2020-04-11T05:55:00	Operator	Date	State	
		Liz	2020-04-11T05:55:00	WARNING3	
d#11223	WARNING4#2020-04-27T16:10:00	Operator	Date	State	
		Sue	2020-04-27T16:10:00	WARNING4	
	WARNING4#2020-04-27T16:15:00	Operator	Date	State	EscalatedTo
		Sue	2020-04-27T16:15:00	WARNING4	Sara

You can now create a new GSI where `EscalatedTo` is the partition key and `State#Date` is the sort key. Notice that only items that have both `EscalatedTo` and `State#Date` attributes appear in the index.

Primary key		Attributes			
Partition key: EscalatedTo	Sort key: State#Date	DeviceID	Operator	Date	State
Sara	WARNING4#2020-04-27T16:15:00	d#11223	Sue	2020-04-27T16:15:00	WARNING4

The rest of the access patterns are summarized as follows:

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
createLogEntryForSpecificDevice	Base table	PutItem	DeviceID=deviceId	State#Date=state#date	
getLogsForSpecificDevice	Base table	Query	DeviceID=deviceId	State#Date begins_with "state1#"	ScanIndexForward = False
getWarningLogsForSpecificDevice	Base table	Query	DeviceID=deviceId	State#Date begins_with "WARNING"	
getLogsForOperatorBetweenTwoDates	GSI-1	Query	Operator=operatorName	Date between date1 and date2	
getEscalatedLogsForSupervisor	GSI-2	Query	EscalatedTo=supervisorName		

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getEscalatedLogsWithSpecificStatusForSupervisor	GSI-2	Query	EscalatedTo=supervisorName	State#Date begins_with "state1#"	
getEscalatedLogsWithSpecificStatusForSupervisorForDate	GSI-2	Query	EscalatedTo=supervisorName	State#Date begins_with "state1#date1"	

Final schema

Here are the final schema designs. To download this schema design as a JSON file, see DynamoDB Examples on GitHub.

Base table

Using NoSQL Workbench with this schema design

You can import this final schema into NoSQL Workbench, a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see the section called “Download”.
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see the section called “Importing an existing model”.
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see the section called “Editing an existing model”.

Using DynamoDB as a data store for an online shop

This use case talks about using DynamoDB as a data store for an online shop (or e-store).

Use case

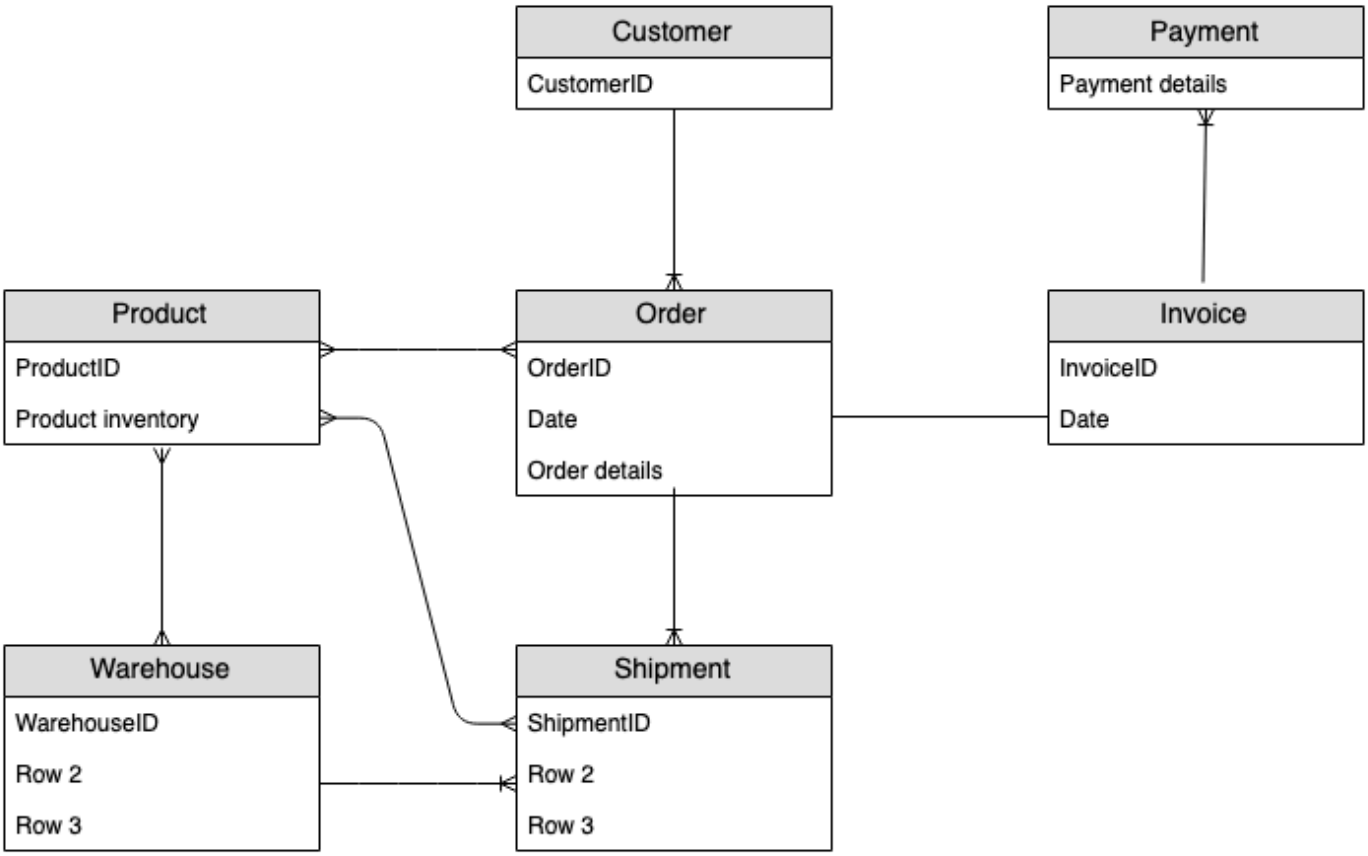
An online store lets users browse through different products and eventually purchase them. Based on the generated invoice, a customer can pay using a discount code or gift card and then pay the remaining amount with a credit card. Purchased products will be picked from one of several warehouses and will be shipped to the provided address. Typical access patterns for an online store include:

- Get customer for a given customerId
- Get product for a given productId
- Get warehouse for a given warehouseId

- Get a product inventory for all warehouses by a productId
- Get order for a given orderId
- Get all products for a given orderId
- Get invoice for a given orderId
- Get all shipments for a given orderId
- Get all orders for a given productId for a given date range
- Get invoice for a given invoiceId
- Get all payments for a given invoiceId
- Get shipment details for a given shipmentId
- Get all shipments for a given warehouseId
- Get inventory of all products for a given warehouseId
- Get all invoices for a given customerId for a given date range
- Get all products ordered by a given customerId for a given date range

Entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using to model DynamoDB as a data store for an online shop.



Access patterns

These are the access patterns we'll be considering when using DynamoDB as a data store for an online shop.

1. `getCustomerByCustomerId`
2. `getProductByProductId`
3. `getWarehouseByWarehouseId`
4. `getProductInventoryByProductId`
5. `getOrderDetailsByOrderId`
6. `getProductByOrderId`
7. `getInvoiceByOrderId`
8. `getShipmentByOrderId`
9. `getOrderByProductIdForDateRange`
10. `getInvoiceByInvoiceId`

11getPaymentByInvoiceId

12getShipmentDetailsByShipmentId

13getShipmentByWarehouseId

14getProductInventoryByWarehouseId

15getInvoiceByCustomerIdForDateRange

16getProductsByCustomerIdForDateRange

Schema design evolution

Using NoSQL Workbench for DynamoDB , import AnOnlineShop_1.json to create a new data model called AnOnlineShop and a new table called OnlineShop. Note that we use the generic names PK and SK for the partition key and sort key. This is a practice used in order to store different types of entities in the same table.

Step 1: Address access pattern 1 (getCustomerByCustomerId)

Import AnOnlineShop_2.json to handle access pattern 1 (getCustomerByCustomerId). Some entities do not have relationships to other entities, so we will use the same value of PK and SK for them. In the example data, note that the keys use a prefix c# in order to distinguish the customerId from other entities that will be added later. This practice is repeated for other entities as well.

To address this access pattern, a GetItem operation can be used with PK=customerId and SK=customerId.

Step 2: Address access pattern 2 (getProductByProductId)

Import AnOnlineShop_3.json to address access pattern 2 (getProductByProductId) for the product entity. The product entities are prefixed by p# and the same sort key attribute has been used to store customerID as well as productID. Generic naming and vertical partitioning allows us to create such item collections for an effective single table design.

To address this access pattern, a GetItem operation can be used with PK=productId and SK=productId.

Step 3: Address access pattern 3 (getWarehouseByWarehouseId)

Import AnOnlineShop_4.json to address access pattern 3 (getWarehouseByWarehouseId) for the warehouse entity. We currently have the customer, product, and warehouse entities added

to the same table. They are distinguished using prefixes and the `EntityType` attribute. A type attribute (or prefix naming) improves the model's readability. The readability would be affected if we simply stored alphanumeric IDs for different entities in the same attribute. It would be difficult to tell one entity from the other in the absence of these identifiers.

To address this access pattern, a `GetItem` operation can be used with `PK=warehouseId` and `SK=warehouseId`.

Base table:

Primary key		Attributes		
Partition key: PK	**Sort key: SK**			
c#12345	c#12345	EntityType	Email	Name
		customer	samaneh@example.com	Samaneh Utter
p#12345	p#12345	EntityType	Detail	Price
		product	{"Name":{"S":"Options Open"},"Description":{"S":"The latest album"}}	100
w#12345	w#12345	EntityType	Address	
		warehouse	{"Country":{"S":"Sweden"},"County":{"S":"Vastra Gotaland"},"City":{"S":"Goteborg"},"Street":{"S":"MainStreet"},"Number":{"S":"20"},"ZipCode":{"S":"41111"}}	

Step 4: Address access pattern 4 (`getProductInventoryByProductId`)

Import AnOnlineShop_5.json to address access pattern 4 (`getProductInventoryByProductId`). `warehouseItem` entity is used to keep track of the number of products in each warehouse. This item would normally be updated when a product is added or removed from a warehouse. As seen in the ERD, there is a many-to-many relationship between `product` and `warehouse`. Here, the one-to-many relationship from `product` to `warehouse` is modeled as `warehouseItem`. Later on, the one-to-many relationship from `warehouse` to `product` will be modeled as well.

Access pattern 4 can be addressed with a query on `PK=ProductId` and `SK begins_with "w#"`.

For more information about `begins_with()` and other expressions that can be applied to sort keys, see Key Condition Expressions.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
c#12345	c#12345	EntityType	Email	Name
		customer	samaneh@example.com	Samaneh Utter
	p#12345	EntityType	Detail	Price
		product	{"Name":{"S":"Options Open"},"Description":{"S":"The latest album"}}	100
p#12345	w#12345	EntityType	Quantity	
		warehouseItem	50	
w#12345	w#12345	EntityType	Address	
		warehouse	{"Country":{"S":"Sweden"},"County":{"S":"Vastra Gotaland"},"City":{"S":"Goteborg"},"Street":{"S":"MainStreet"},"Number":{"S":"20"},"ZipCode":{"S":"41111"}}	

Step 5: Address access patterns 5 (`getOrderDetailsByOrderId`) and 6 (`getProductByOrderId`)

Add some more `customer`, `product`, and `warehouse` items to the table by importing AnOnlineShop_6.json. Then, import AnOnlineShop_7.json to build an item collection for `order` that can address access patterns 5 (`getOrderDetailsByOrderId`) and 6 (`getProductByOrderId`). You can see the one-to-many relationship between `order` and `product` modeled as orderItem entities.

To address access pattern 5 (`getOrderDetailsByOrderId`), query the table with `PK=orderId`. This will provide all information about the order including `customerId` and ordered products.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
o#12345	c#12345	EntityType	Date	
		order	2020-06-21T19:10:00	
	p#12345	EntityType	Price	Quantity
		orderItem	100	2
	p#99887	EntityType	Price	Quantity
		orderItem	40	5

To address access pattern 6 (`getProductByOrderId`), we need to read products in an `order` only. Query the table with `PK=orderId` and `SK begins_with "p#"` to accomplish this.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
	c#12345	EntityType	Date	
		order	2020-06-21T19:10:00	
o#12345	p#12345	EntityType	Price	Quantity
		orderItem	100	2
	p#99887	EntityType	Price	Quantity
		orderItem	40	5

Step 6: Address access pattern 7 (`getInvoiceByOrderId`)

Import AnOnlineShop_8.json to add an `invoice` entity to the *order* item collection to handle access pattern 7 (`getInvoiceByOrderId`). To address this access pattern, you can use a query operation with `PK=orderId` and `SK begins_with "i#"`.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
o#12345	c#12345	EntityType	Date	
		order	2020-06-21T19:10:00	
	i#55443	EntityType	Amount	Date
		invoice	400	2020-06-21T19:18:00
	p#12345	EntityType	Price	Quantity
		orderItem	100	2
	p#99887	EntityType	Price	Quantity
		orderItem	40	5

Step 7: Address access pattern 8 (`getShipmentByOrderId`)

Import AnOnlineShop_9.json to add `shipment` entities to the *order* item collection to address access pattern 8 (`getShipmentByOrderId`). We are extending the same vertically partitioned model by adding more types of entities in the single table design. Notice how the *order* item collection contains the different relationships that an `order` entity has with the `shipment`, `orderItem`, and `invoice` entities.

To get shipments by `orderId`, you can perform a query operation with `PK=orderId` and SK `begins_with “sh#”`.

Base table:

Primary key		Attributes				
Partition key: PK	Sort key: SK					
o#12345	c#12345	EntityType	Date			
		order	2020-06-21T19:10:00			
	i#55443	EntityType	Amount	Date		
		invoice	400	2020-06-21T19:18:00		
	p#12345	EntityType	Price	Quantity		
		orderItem	100	2		
	p#99887	EntityType	Price	Quantity		
		orderItem	40	5		
	sh#88899	EntityType	Address	Type	Date	Warehouseld
		shipment	{"Country":{"S":"Sweden"},"County":{"S":"Vastra Gotaland"},"City":{"S":"Goteborg"},"Street":{"S":"Slanbarsvagen"},"Number":{"S":"34"},"ZipCode":{"S":"41787"}}	Express	2020-06-22T08:20:00	w#12376
	sh#98765	EntityType	Address	Type	Date	Warehouseld
		shipment	{"Country":{"S":"Sweden"},"County":{"S":"Vastra Gotaland"},"City":{"S":"Goteborg"},"Street":{"S":"Slanbarsvagen"},"Number":{"S":"34"},"ZipCode":{"S":"41787"}}	Express	2020-06-22T10:20:00	w#12345

Step 8: Address access pattern 9 (`getOrderByProductIdForDateRange`)

We created an *order* item collection in the previous step. This access pattern has new lookup dimensions (`ProductID` and `Date`) which requires you to scan the whole table and filter out relevant records to fetch targeted items. In order to address this access pattern, we'll need to create a global secondary index (GSI). Import AnOnlineShop_10.json to create a new item collection using the GSI that makes it possible to retrieve `orderItem` data from several *order* item collections. The data now has `GSI1-PK` and `GSI1-SK` which will be `GSI1`'s partition key and sort key, respectively.

DynamoDB automatically populates items which contain a GSI's key attributes from the table to the GSI. There is no need to manually do any additional inserts into the GSI.

To address access pattern 9, perform a query on `GSI1` with `GSI1-PK=productId` and `GSI1SK between (date1, date2)`.

Base table:

Primary key		Attributes				
Partition key: PK	**Sort key: SK**					
o#12345	p#12345	EntityType	GSI1-PK	GSI1-SK	Price	Quantity
		orderItem	p#12345	2020-06-21T19:18:00	100	2
	p#99887	EntityType	GSI1-PK	GSI1-SK	Price	Quantity
		orderItem	p#99887	2020-06-21T19:20:00	40	5

GSI1:

Primary key		Attributes				
Partition key: GSI1-PK	**Sort key: GSI1-SK**					
p#12345	2020-06-21T19:18:00	PK	SK	EntityType	Quantity	Price
		o#12345	p#12345	orderItem	2	100
p#99887	2020-06-21T19:20:00	PK	SK	EntityType	Quantity	Price
		o#12345	p#99887	orderItem	5	40

Step 9: Address access patterns 10 (`getInvoiceByInvoiceId`) and 11 (`getPaymentByInvoiceId`)

Import AnOnlineShop_11.json to address access patterns 10 (`getInvoiceByInvoiceId`) and 11 (`getPaymentByInvoiceId`), both of which are related to `invoice`. Even though these are two different access patterns, they are realized using the same key condition. `Payments` are defined as an attribute with the map data type on the `invoice` entity.

> **Note**
>
> `GSI1-PK` and `GSI1-SK` is overloaded to store information about different entities so that multiple access patterns can be served from the same GSI. For more information about GSI overloading, see Overloading Global Secondary Indexes in DynamoDB.

To address access pattern 10 and 11, query `GSI1` with `GSI1-PK=invoiceId` and `GSI1-SK=invoiceId`.

GSI1:

Primary key		Attributes							
Partition key: GSI1-PK	Sort key: GSI1-SK	PK	SK	EntityType	GSI2-PK	GSI2-SK	Detail	Amount	Date
i#55443	i#55443	o#12345	i#55443	invoice	c#12345	i#2020-06-21T19:18:00	{"Payments":{"L":[{"M":{"Type":{"S":"GiftCard"},"Amount":{"N":"100"},"Data":{"S":"GiftCard data here..."}}},{"M":{"Type":{"S":"MasterCard"},"Amount":{"N":"300"},"Data":{"S":"Payment data here..."}}}]}}	400	2020-06-21T19:18:00

Step 10: Address access patterns 12 (`getShipmentDetailsByShipmentId`) and 13 (`getShipmentByWarehouseId`)

Import AnOnlineShop_12.json to address access patterns 12 (`getShipmentDetailsByShipmentId`) and 13 (`getShipmentByWarehouseId`).

Notice that `shipmentItem` entities are added to the *order* item collection on the base table in order to be able to retrieve all details about an order in a single query operation.

Base table:

Primary key		Attributes							
Partition key: PK	Sort key: SK								
o#12345	sh#88899	EntityType	GSI1-PK	GSI1-SK	GSI2-PK	GSI2-SK	Address	Type	Date
		shipment	sh#88899	sh#88899	w#12376	sh#88899	{"Country": {"S":"Sweden"},"County": {"S":"Vastra Gotaland"},"City": {"S":"Goteborg"},"Street": {"S":"Slanbarsvagen"},"Number": {"S":"34"},"ZipCode": {"S":"41787"}}	Express	2020-06-22T08:20:00
	sh#98765	EntityType	GSI1-PK	GSI1-SK	GSI2-PK	GSI2-SK	Address	Type	Date
		shipment	sh#98765	sh#98765	w#12345	sh#98765	{"Country": {"S":"Sweden"},"County": {"S":"Vastra Gotaland"},"City": {"S":"Goteborg"},"Street": {"S":"Slanbarsvagen"},"Number": {"S":"34"},"ZipCode": {"S":"41787"}}	Express	2020-06-22T10:20:00
	shp#12345	EntityType	GSI1-PK	GSI1-SK	Quantity				
		shipmentItem	sh#98765	p#99887	3				
	shp#54321	EntityType	GSI1-PK	GSI1-SK	Quantity				
		shipmentItem	sh#88899	p#99887	2				
	shp#55555	EntityType	GSI1-PK	GSI1-SK	Quantity				
		shipmentItem	sh#98765	p#12345	2				

The `GSI1` partition and sort keys have already been used to model a one-to-many relationship between `shipment` and `shipmentItem`. To address access pattern 12 (`getShipmentDetailsByShipmentId`), query `GSI1` with `GSI1-PK=shipmentId` and `GSI1-SK=shipmentId`.

GSI1:

Primary key		Attributes							
Partition key: GSI1-PK	Sort key: GSI1-SK								
	p#99887	PK	SK	EntityType	Quantity				
		o#12345	shp#54321	shipmentItem	2				
sh#88899	sh#88899	PK	SK	EntityType	GSI2-PK	GSI2-SK	Address	Type	Date
		o#12345	sh#88899	shipment	w#12376	sh#88899	{"Country":{"S":"Sweden"},"County":{"S":"Vastra Gotaland"},"City":{"S":"Goteborg"},"Street":{"S":"Slanbarsvagen"},"Number":{"S":"34"},"ZipCode":{"S":"41787"}}	Express	2020-06-22T08:20:00
sh#98765	p#12345	PK	SK	EntityType	Quantity				
		o#12345	shp#55555	shipmentItem	2				
	p#99887	PK	SK	EntityType	Quantity				
		o#12345	shp#12345	shipmentItem	3				
	sh#98765	PK	SK	EntityType	GSI2-PK	GSI2-SK	Address	Type	Date
		o#12345	sh#98765	shipment	w#12345	sh#98765	{"Country":{"S":"Sweden"},"County":{"S":"Vastra Gotaland"},"City":{"S":"Goteborg"},"Street":{"S":"Slanbarsvagen"},"Number":{"S":"34"},"ZipCode":{"S":"41787"}}	Express	2020-06-22T10:20:00

We'll need to create another GSI (`GSI2`) to model the new one-to-many relationship between `warehouse` and `shipment` for access pattern 13 (`getShipmentByWarehouseId`). To address this access pattern, query `GSI2` with `GSI2-PK=warehouseId` and `GSI2-SK begins_with "sh#"`.

GSI2:

Primary key		Attributes							
Partition key: GSI2-PK	Sort key: GSI2-SK								
		PK	SK	EntityType	GSI1-PK	GSI1-SK	Address	Type	Date
w#12376	sh#88899	o#12345	sh#88899	shipment	sh#88899	sh#88899	{"Country": {"S":"Sweden"},"County": {"S":"Vastra Gotaland"},"City": {"S":"Goteborg"},"Street": {"S":"Slanbarsvagen"},"Number": {"S":"34"},"ZipCode": {"S":"41787"}}	Express	2020-06-22T08:20:00
		PK	SK	EntityType	GSI1-PK	GSI1-SK	Address	Type	Date
w#12345	sh#98765	o#12345	sh#98765	shipment	sh#98765	sh#98765	{"Country": {"S":"Sweden"},"County": {"S":"Vastra Gotaland"},"City": {"S":"Goteborg"},"Street": {"S":"Slanbarsvagen"},"Number": {"S":"34"},"ZipCode": {"S":"41787"}}	Express	2020-06-22T10:20:00

Step 11: Address access patterns 14 (`getProductInventoryByWarehouseId`) 15 (`getInvoiceByCustomerIdForDateRange`), and 16 (`getProductsByCustomerIdForDateRange`)

Import AnOnlineShop_13.json to add data related to the next set of access patterns. To address access pattern 14 (`getProductInventoryByWarehouseId`), query `GSI2` with `GSI2-PK=warehouseId` and `GSI2-SK begins_with “p#”`.

GSI2:

Primary key		Attributes							
Partition key: GSI2-PK	Sort key: GSI2-SK								
w#12345	p#12345	PK	SK	EntityType	Quantity				
		p#12345	w#12345	warehouseItem	50				
	p#99887	PK	SK	EntityType	Quantity				
		p#99887	w#12345	warehouseItem	4				
c#12345	i#2020-06-21T19:18:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Detail	Amount	Date
		o#12345	i#55443	invoice	i#55443	i#55443	{"Payments":{"L":[{"M":{"Type":{"S":"GiftCard"},"Amount":{"N":"100"},"Data":{"S":"GiftCard data here..."}}},{"M":{"Type":{"S":"MasterCard"},"Amount":{"N":"300"},"Data":{"S":"Payment data here..."}}}]}}	400	2020-06-21T19:18:00
	p#2020-06-21T19:18:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#12345	orderItem	p#12345	2020-06-21T19:18:00	100	2	
	p#2020-06-21T19:20:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#99887	orderItem	p#99887	2020-06-21T19:20:00	40	5	

To address access pattern 15 (`getInvoiceByCustomerIdForDateRange`), query `GSI2` with `GSI2-PK=customerId` and `GSI2-SK between (i#date1, i#date2)`.

GSI2:

Primary key		Attributes							
Partition key: GSI2-PK	Sort key: GSI2-SK								
w#12345	p#12345	PK	SK	EntityType	Quantity				
		p#12345	w#12345	warehouseItem	50				
	p#99887	PK	SK	EntityType	Quantity				
		p#99887	w#12345	warehouseItem	4				
c#12345	i#2020-06-21T19:18:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Detail	Amount	Date
		o#12345	i#55443	invoice	i#55443	i#55443	{"Payments":{"L":[{"M":{"Type":{"S":"GiftCard"},"Amount":{"N":"100"},"Data":{"S":"GiftCard data here..."}}},{"M":{"Type":{"S":"MasterCard"},"Amount":{"N":"300"},"Data":{"S":"Payment data here..."}}}]}}	400	2020-06-21T19:18:00
	p#2020-06-21T19:18:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#12345	orderItem	p#12345	2020-06-21T19:18:00	100	2	
	p#2020-06-21T19:20:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#99887	orderItem	p#99887	2020-06-21T19:20:00	40	5	

To address access pattern 16 (`getProductsByCustomerIdForDateRange`), query `GSI2` with `GSI2-PK=customerId` and `GSI2-SK between (p#date1, p#date2)`.

GSI2:

Primary key		Attributes

Note

In NoSQL Workbench, *facets* represent an application's different data access patterns for DynamoDB. Facets give you a way to view a subset of the data in a table, without having to see records that don't meet the constraints of the facet. Facets are considered a visual data modeling tool, and don't exist as a usable construct in DynamoDB as they are purely an aid for modeling access patterns.

Import AnOnlineShop_facets.json to see the facets for this use case.

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/GSI/LSI	Operation	Partition key value	Sort key value
getCustomerByCustomerId	Base table	GetItem	PK=customerId	SK=customerId
getProductByProductId	Base table	GetItem	PK=productId	SK=productId
getWarehouseByWarehouseId	Base table	GetItem	PK=warehouseId	SK=warehouseId
getProductInventoryByProductId	Base table	Query	PK=productId	SK begins_with "w#"
getOrderDetailsByOrderId	Base table	Query	PK=orderId	
getProductByOrderId	Base table	Query	PK=orderId	SK begins_with "p#"
getInvoiceByOrderId	Base table	Query	PK=orderId	SK begins_with "i#"
getShipmentByOrderId	Base table	Query	PK=orderId	SK begins_with "sh#"
getOrderByProductIdForDateRange	GSI1	Query	PK=productId	SK between date1 and date2
getInvoiceByInvoiceId	GSI1	Query	PK=invoiceId	SK=invoiceId

Access pattern	Base table/GSI/LSI	Operation	Partition key value	Sort key value
getPaymentByInvoiceId	GSI1	Query	PK=invoiceId	SK=invoiceId

Using NoSQL Workbench with this schema design

You can import this final schema into NoSQL Workbench, a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see the section called “Download”.
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see the section called “Importing an existing model”.
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see the section called “Editing an existing model”.

Best practices for modeling relational data in DynamoDB

This section provides best practices for modeling relational data in Amazon DynamoDB. First, we introduce traditional data modeling concepts. Then, we describe the advantages of using DynamoDB over traditional relational database management systems—how it eliminates the need for JOIN operations and reduces overhead.

This section then explains how to design a DynamoDB table that scales efficiently, and provides an example of how to model relational data in DynamoDB.

Topics

- Traditional relational database models
- How DynamoDB eliminates the need for JOIN operations
- How DynamoDB transactions eliminate overhead to the write process
- First steps for modeling relational data in DynamoDB
- Example of modeling relational data in DynamoDB

Traditional relational database models

A traditional relational database management system (RDBMS) stores data in a normalized relational structure. The objective of the relational data model is to reduce the duplication of data (through normalization) to support referential integrity and reduce data anomalies.

The following schema is an example of a relational data model for a generic order-entry application. The application supports a human resources schema that backs the operational and business support systems of a theoretical manufacturer.

As a non-relational database service, DynamoDB offers many advantages over traditional relational database management systems.

How DynamoDB eliminates the need for JOIN operations

An RDBMS uses a structure query language (SQL) to return data to the application. Because of the normalization of the data model, such queries typically require the use of the `JOIN` operator to combine data from one or more tables.

For example, to generate a list of purchase order items sorted by the quantity in stock at all warehouses that can ship each item, you could issue the following SQL query against the preceding schema.

```
SELECT * FROM Orders
  INNER JOIN Order_Items ON Orders.Order_ID = Order_Items.Order_ID
  INNER JOIN Products ON Products.Product_ID = Order_Items.Product_ID
  INNER JOIN Inventories ON Products.Product_ID = Inventories.Product_ID
  ORDER BY Quantity_on_Hand DESC
```

SQL queries of this kind can provide a flexible API for accessing data, but they require a significant amount of processing. Each join in the query increases the runtime complexity of the query because the data for each table must stage and then be assembled to return the result set.

Additional factors that can impact how long it takes the queries to run are the size of the tables and whether the columns being joined have indexes. The preceding query initiates complex queries across several tables and then sorts the result set.

Eliminating the need for `JOIN`s is at the heart of NoSQL data modeling. This is why Amazon built DynamoDB to support Amazon.com, and why DynamoDB can deliver consistent performance at any scale. Given the runtime complexity of SQL queries and `JOIN`s, RDBMS performance is not constant at scale. This causes performance issues as customer applications grow.

While normalizing data does reduce the amount of data stored to disk, often the most constrained resources that impact performance are CPU time and network latency.

DynamoDB is built to minimize both constraints by eliminating `JOIN`s (and encouraging denormalization of data) and optimizing the database architecture to fully answer an application query with a single request to an item. These qualities enable DynamoDB to provide single-digit, millisecond performance at any scale. This is because the runtime complexity for DynamoDB operations is constant, regardless of data size, for common access patterns.

How DynamoDB transactions eliminate overhead to the write process

Another factor that can slow down an RDBMS is the use of transactions to write to a normalized schema. As shown in the example, relational data structures used by most online transaction processing (OLTP) applications must be broken down and distributed across multiple logical tables when they are stored in an RDBMS.

Therefore, an ACID-compliant transaction framework is necessary to avoid race conditions and data integrity issues that could occur if an application tries to read an object that is in the process of being written. Such a transaction framework, when coupled with a relational schema, can add significant overhead to the write process.

The implementation of transactions in DynamoDB prohibits common scaling issues that are found with an RDBMS. DynamoDB does this by issuing a transaction as a single API call and bounding the number of items that can be accessed in that single transaction. Long-running transactions can cause operational issues by holding locks on the data either for a long time, or perpetually, because the transaction is never closed.

To prevent such issues in DynamoDB, transactions were implemented with two distinct API operations: `TransactWriteItems` and `TransactGetItems`. These API operations do not have begin and end semantics that are common in an RDBMS. Further, DynamoDB has a 100-item access limit within a transaction to similarly prevent long-running transactions. To learn more about DynamoDB transactions, see Working with transactions.

For these reasons, when your business requires a low-latency response to high-traffic queries, taking advantage of a NoSQL system generally makes technical and economic sense. Amazon DynamoDB helps solve the problems that limit relational system scalability by avoiding them.

The performance of an RDBMS does not typically scale well for the following reasons:

- It uses expensive joins to reassemble required views of query results.
- It normalizes data and stores it on multiple tables that require multiple queries to write to disk.
- It generally incurs the performance costs of an ACID-compliant transaction system.

DynamoDB scales well for these reasons:

- Schema flexibility lets DynamoDB store complex hierarchical data within a single item.
- Composite key design lets it store related items close together on the same table.

- Transactions are performed in a single operation. The limit for the number of items that can be accessed is 100, to avoid long-running operations.

Queries against the data store become much simpler, often in the following form:

```
SELECT * FROM Table_X WHERE Attribute_Y = "somevalue"
```

DynamoDB does far less work to return the requested data compared to the RDBMS in the earlier example.

First steps for modeling relational data in DynamoDB

> **Note**
>
> NoSQL design requires a different mindset than RDBMS design. For an RDBMS, you can create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. By contrast, in Amazon DynamoDB, you shouldn't start designing your schema until you know the questions that it needs to answer. Understanding the business problems and the application use cases up front is absolutely essential.

To start designing a DynamoDB table that will scale efficiently, you must take several steps first to identify the access patterns that are required by the operations and business support systems (OSS/BSS) that it needs to support:

- For new applications, review user stories about activities and objectives. Document the various use cases you identify, and analyze the access patterns that they require.
- For existing applications, analyze query logs to find out how people are currently using the system and what the key access patterns are.

After completing this process, you should end up with a list that might look something like the following.

Access Patterns for Order Entry Application

Pattern #	Access Pattern Description
1	Look up Employee Details by Employee ID
2	Query Employee Details by Employee Name
3	Find an Employee's Phone Number(s)
4	Find a Customer's Phone Number(s)
5	Get Orders for Customer within Date Range
6	Show all Open Orders within Date Range
7	See all Employees hired recently
8	Find all Employees in Warehouse
9	Get all Items on Order for Product
10	Get Inventories for Product at all Warehouses
11	Get Customers by Account Rep
12	Get Orders by Account Rep
13	Get Employees with Job Title
14	Get Inventory by Product and Warehouse
15	Get Total Product Inventory

In a real application, your list might be much longer. But this collection represents the range of query pattern complexity that you might find in a production environment.

A modern approach to DynamoDB schema design uses aggregate-oriented principles, grouping data based on access patterns rather than rigid entity boundaries. This approach considers multiple design patterns:

- *Single Table Design* - Using composite sort keys, overloaded global secondary indexes, and adjacency list patterns to store multiple entity types in one table
- *Multi-Table Design* - Using separate tables for entities with independent operational characteristics and low access correlation, with strategic GSIs for cross-entity queries
- *Aggregate Design* - Embedding related data when always accessed together (Order + OrderItems) or using item collections for identifying relationships (Product + Inventory)

The choice between these approaches depends on your specific access patterns, data characteristics, and operational requirements. You can use these elements to structure the data so that an application can retrieve whatever it needs for a given access pattern using a single query on a table or index.

> **Note**
>
> The choice between single-table and multi-table design depends on your specific requirements. Single-table design works well when entities have high access correlation and similar operational characteristics. Multi-table design is preferred when entities have independent operational requirements, different access patterns, or when you need clear operational boundaries. The example in this guide demonstrates a multi-table approach with strategic aggregation and denormalization.

To use NoSQL Workbench for DynamoDB to help visualize your partition key design, see Building data models with NoSQL Workbench.

Example of modeling relational data in DynamoDB

This example describes how to model relational data in Amazon DynamoDB. The DynamoDB table design corresponds to the relational order entry schema that is shown in Relational modeling. This design uses multiple specialized tables rather than a single adjacency list, providing clear operational boundaries while leveraging strategic GSIs to serve all access patterns efficiently.

The design approach uses aggregate-oriented principles, grouping data based on access patterns rather than rigid entity boundaries. Key design decisions include using separate tables for entities with low access correlation, embedding related data when always accessed together, and using item collections for identifying relationships.

The following tables and their accompanying indexes support the relational order entry schema:

Employee Table Design

The Employee table stores employee information as a single entity per item, optimized for direct employee lookups and supporting multiple query patterns through strategic GSIs. This table demonstrates the principle of designing separate tables for entities with independent operational characteristics and low cross-entity access correlation.

The table uses a simple partition key (employee_id) without a sort key, as each employee is a distinct entity. Four GSIs enable efficient querying by different attributes:

- *EmployeeByName GSI* - Uses INCLUDE projection with all employee attributes to support complete employee detail retrieval by name, handling potential duplicate names with employee_id as sort key
- *EmployeeByWarehouse GSI* - Uses INCLUDE projection with only essential attributes (name, job_title, hire_date) to minimize storage costs while supporting warehouse-based queries
- *EmployeeByJobTitle GSI* - Enables role-based queries with INCLUDE projection for reporting and organizational analysis
- *EmployeeByHireDate GSI* - Uses a static partition key value "EMPLOYEE" with hire_date as sort key to enable efficient date range queries for recent hires. Since employee additions/updates are typically under 1,000 WCU, a single partition can handle the write load without hot partition issues

Employee Table - Base Table Structure

employee_id (PK)	name	phone_numbers	warehouse_id	job_title	hire_date	entity_type
emp_001	John Smith	["+1-555-0101"]	wh_sea	Manager	2024-03-15	EMPLOYEE

Customer Table Design

The Customer table maintains customer information with strategic denormalization of account_rep_id to enable efficient account representative queries. This design choice trades slight storage overhead for query performance, eliminating the need for joins between customer and account representative data.

The table supports multiple phone numbers per customer using a list attribute, demonstrating DynamoDB's schema flexibility. The single GSI enables account representative workflows:

- *CustomerByAccountRep GSI* - Uses INCLUDE projection with name and email attributes to support account rep customer management without requiring full customer record retrieval

Customer Table - Base Table Structure

customer_id (PK)	name	phone_numbers	email	account_rep_id
cust_001	Acme Corp	["+1-555-1001"]	contact@acme.com	rep_001
cust_002	TechStart Inc	["+1-555-1002", "+1-555-1003"]	info@techstart.com	rep_001
cust_003	Global Traders	["+1-555-1004"]	sales@globaltraders.com	rep_002

rep_003	cust_005	FastShip Co	support@fastship.com

Order Table Design

The Order table uses vertical partitioning with separate items for order headers and order items. This design enables efficient product-based queries while maintaining all order components within the same partition for efficient access. Each order consists of multiple items:

- *Order Header* - Contains order metadata with PK=order_id, SK=order_id
- *Order Items* - Individual line items with PK=order_id, SK=product_id, enabling direct product queries

> **Note**
>
> This vertical partitioning approach trades the simplicity of embedded order items for enhanced query flexibility. Each order item becomes a separate DynamoDB item, enabling efficient product-based queries while maintaining all order data within the same partition for efficient retrieval in a single request.

The table includes strategic denormalization of account_rep_id (duplicated from Customer table) to enable direct account representative queries without requiring customer lookups. For high-

throughput write scenarios, OPEN orders include status and shard attributes to enable write sharding across multiple partitions.

Four GSIs support different query patterns with optimized projections:

- *OrderByCustomerDate GSI* - Uses INCLUDE projection with order summary and item details to support customer order history with date range filtering
- *OpenOrdersByDate GSI (Sparse, Sharded)* - Uses multi-attribute partition key (status + shard) with 5 shards to distribute 5,000 WPS (writes per second) across partitions (1,000 WPS each, matching DynamoDB's 1,000 WCU per partition limit). Only indexes OPEN orders (20% of total), which can help reduce GSI storage costs. Requires parallel queries across all 5 shards with client-side result merging
- *OrderByAccountRep GSI* - Uses INCLUDE projection with order summary attributes to support account representative workflows without full order details
- *ProductInOrders GSI* - Created from OrderItem records (PK=order_id, SK=product_id), this GSI enables queries to find all orders containing a specific product. Uses INCLUDE projection with order context (customer_id, order_date, quantity) for product demand analysis

Order Table - Base Table Structure (Vertical Partitioning)

PK	SK	customer_id	order_date	status	account_rep_id	quantity	price	shard
ord_001	ord_001	cust_001	2025-11-5	CLOSED	rep_001			
ord_001	prod_100					5	25.00	
ord_002	ord_002	cust_001	2025-12-0	OPEN	rep_001			0
ord_002	prod_101					10	15.00	
ord_003	ord_003	cust_002	2026-01-5	OPEN	rep_001			2
ord_003	prod_100					3	25.00	

OrderByCustomerDate GSI - Supporting Customer Order Queries

customer_id (GSI-PK)	order_date (GSI-SK)	order_id	status	total_amount	order_items	shard
cust_001	2025-11-15	ord_001	CLOSED	225.00	[{product_id: "prod_100", qty: 5}]	
cust_001	2025-12-20	ord_002	OPEN	150.00	[{product_id: "prod_101", qty: 10}]	0
cust_002	2026-01-05	ord_003	OPEN	175.00	[{product_id: "prod_100", qty: 3}]	2
cust_003	2025-10-10	ord_004	CLOSED	250.00	[{product_id: "prod_101", qty: 5}]	
cust_004	2026-01-03	ord_005	OPEN	200.00	[{product_id: "prod_100", qty: 20}]	1

OpenOrdersByDate GSI (Sparse, Sharded) - Supporting High-Throughput Open Order Queries

status (GSI-PK-1)	shard (GSI-PK-2)	order_date (SK)	order_id	customer_id	account_rep_id	order_items	total_amount
OPEN	0	2025-12-20	ord_002	cust_001	rep_001	[{product_id: "prod_101", qty: 10}]	150.00
OPEN	1	2026-01-03	ord_005	cust_004	rep_002	[{product_id: "prod_100", qty: 20}]	200.00
OPEN	2	2026-01-05	ord_003	cust_002	rep_001	[{product_id: "prod_100", qty: 3}]	175.00

OrderByAccountRep GSI - Supporting Account Rep Order Queries

account_rep_id (GSI-PK)	order_date (GSI-SK)	order_id	customer_id	status	total_amount
rep_001	2025-11-15	ord_001	cust_001	CLOSED	225.00
rep_001	2025-12-20	ord_002	cust_001	OPEN	150.00
rep_001	2026-01-05	ord_003	cust_002	OPEN	175.00
rep_002	2025-10-10	ord_004	cust_003	CLOSED	250.00
rep_002	2026-01-03	ord_005	cust_004	OPEN	200.00

ProductInOrders GSI - Supporting Product Order Queries

product_id (GSI-PK)	order_id (GSI-SK)	customer_id	order_date	quantity
prod_100	ord_001	cust_001	2025-11-15	5
prod_100	ord_003	cust_002	2026-01-05	3
prod_101	ord_002	cust_001	2025-12-20	10

Product Table Design

The Product table uses the item collection pattern to store both product metadata and inventory data within the same partition. This design leverages the identifying relationship between products and inventory - inventory cannot exist without a parent product. Using PK=product_id with SK=product_id for product metadata and SK=warehouse_id for inventory items eliminates the need for a separate Inventory table and GSI, reducing costs by approximately 50%.

This pattern enables efficient queries for both individual warehouse inventory (GetItem with composite key) and all warehouse inventory for a product (Query on partition key). The total_inventory attribute in the product metadata item provides denormalized aggregation for quick total inventory lookups.

Product Table - Base Table Structure (Item Collection Pattern)

product_id (PK)	warehouse_id (SK)	product_name	category	unit_price	inventory_quantity	total_inventory
prod_100	prod_100	Widget A	Hardware	25.00		500
prod_100	wh_sea				200	
prod_100	wh_pdx				150	
prod_100	wh_atl				150	
prod_101	prod_101	Gadget B	Electronics	50.00		300
prod_101	wh_sea				100	
prod_101	wh_pdx				200	

Each table is designed with specific Global Secondary Indexes (GSIs) to support the required access patterns efficiently. The design uses aggregate-oriented principles with strategic denormalization and sparse indexing to optimize both performance and cost.

Key design optimizations include:

- *Sparse GSI* - OpenOrdersByDate only indexes OPEN orders (20% of total), which can help reduce GSI storage costs
- *Item Collection Pattern* - Product table stores inventory using PK=product_id, SK=warehouse_id to eliminate separate inventory table
- *Order + OrderItems Aggregation* - Embedded as single item due to 100% access correlation
- *Strategic Denormalization* - account_rep_id duplicated in Order table for efficient queries

Finally, you can revisit the access patterns that were defined earlier. The following table shows how each access pattern is efficiently supported using the multi-table design with strategic GSIs. Each pattern uses either direct key lookups or single GSI queries, avoiding expensive scans and providing consistent performance at any scale.

S. No.	Access patterns	Query conditions
1	Look up Employee Details by Employee ID	Employee Table: GetItem(employee_id="emp_001")
2	Query Employee Details by Employee Name	EmployeeByName GSI: Query(name="John Smith")
3	Find an Employee's Phone Number(s)	Employee Table: GetItem(employee_id="emp_001")
4	Find a Customer's Phone Number(s)	Customer Table: GetItem(customer_id="cust_001")
5	Get Orders for Customer within Date Range	OrderByCustomerDate GSI: Query(customer_id="cust_001", order_date BETWEEN "2025-01-01" AND "2025-12-31")
6	Show all Open Orders within Date Range	OpenOrdersByDate GSI: Query 5 shards in parallel with multi-attribute PK (status="OPEN" + shard=0-4), SK=order_date BETWEEN "2025-01-01" AND "2025-12-31", merge results
7	See all Employees hired recently	EmployeeByHireDate GSI: Query(entity_type="EMPLOYEE", hire_date >= "2025-01-01")
8	Find all Employees in Warehouse	EmployeeByWarehouse GSI: Query(warehouse_id="wh_sea")

S. No.	Access patterns	Query conditions
9	Get all Items on Order for Product	ProductInOrders GSI: Query(product_id="prod_100")
10	Get Inventories for Product at all Warehouses	Product Table: Query(product_id="prod_100")
11	Get Customers by Account Rep	CustomerByAccountRep GSI: Query(account_rep_id="rep_001")
12	Get Orders by Account Rep	OrderByAccountRep GSI: Query(account_rep_id="rep_001")
13	Get Employees with Job Title	EmployeeByJobTitle GSI: Query(job_title="Manager")
14	Get Inventory by Product and Warehouse	Product Table: GetItem(product_id="prod_100", warehouse_id="wh_sea")
15	Get Total Product Inventory	Product Table: GetItem(product_id="prod_100", warehouse_id="prod_100")

Migrating to DynamoDB from a relational database

Migrating a relational database into DynamoDB requires careful planning to ensure a successful outcome. This guide will help you understand how this process works, what tools you have available, and then how to evaluate potential migration strategies and select one that'll fit your requirements.

Topics

- Reasons to migrate to DynamoDB
- Considerations when migrating a relational database to DynamoDB
- Understanding how a migration to DynamoDB works
- Tools to help migrate to DynamoDB
- Choosing the appropriate strategy to migrate to DynamoDB
- Performing an offline migration to DynamoDB
- Performing a hybrid migration to DynamoDB
- Performing an online migration to DynamoDB by migrating each table 1:1
- Perform an online migration to DynamoDB using a custom staging table

Reasons to migrate to DynamoDB

Migrating to Amazon DynamoDB presents a range of compelling benefits for businesses and organizations. Here are some key advantages that make DynamoDB an attractive choice for database migration:

- **Scalability**: DynamoDB is designed to handle massive workloads and scale seamlessly to accommodate growing data volumes and traffic. With DynamoDB, you can easily scale your database up or down based on demand, ensuring that your applications can handle sudden spikes in traffic without compromising performance.
- **Performance**: DynamoDB offers low-latency data access, enabling applications to retrieve and process data with exceptional speed. Its distributed architecture ensures that read and write operations are distributed across multiple nodes, delivering consistent, single-digit millisecond response times even at high request rates.
- **Fully managed**: DynamoDB is a fully managed service provided by AWS. This means that AWS handles the operational aspects of database management, including provisioning, configuration,

patching, backups, and scaling. This allows you to focus more on developing your applications and less on database administration tasks.

- **Serverless architecture**: DynamoDB supports a serverless model, known as DynamoDB on-demand, where you pay only for the actual read and write requests your application makes with no upfront capacity provisioning required. This pay-per-request model offers cost efficiency and minimal operational overhead, as you only pay for the resources you consume without the need to provision and monitor capacity.
- **NoSQL flexibility**: Unlike traditional relational databases, DynamoDB follows a NoSQL data model, providing flexibility in schema design. With DynamoDB, you can store structured, semi-structured, and unstructured data, making it well-suited for handling diverse and evolving data types. This flexibility enables faster development cycles and easier adaptation to changing business requirements.
- **High availability and durability**: DynamoDB replicates data across multiple availability zones within a Region, ensuring high availability and data durability. It automatically handles replication, failover, and recovery, minimizing the risk of data loss or service disruptions. DynamoDB provides an availability SLA of up to 99.999%.
- **Security and compliance**: DynamoDB integrates with AWS Identity and Access Management for fine-grained access control. It provides encryption at rest and in-transit, ensuring the security of your data. DynamoDB also adheres to various compliance standards, including HIPAA, PCI DSS, and GDPR, enabling you to meet regulatory requirements.
- **Integration with AWS Ecosystem**: As part of the AWS ecosystem, DynamoDB seamlessly integrates with other AWS services, such as AWS Lambda, CloudFormation, and AWS AppSync. This integration enables you to build serverless architectures, leverage infrastructure as code, and create real-time data-driven applications.

Considerations when migrating a relational database to DynamoDB

Relational database systems and NoSQL databases have different strengths and weaknesses. These differences make database design different between the two systems.

Type of task	Relational database	NoSQL database
Querying the database	In relational databases, data can be queried flexibly,	In a NoSQL database such as DynamoDB, data can be

Type of task	Relational database	NoSQL database
	but queries are relatively expensive and don't scale well in high-traffic situations (see First steps for modeling relational data in DynamoDB). A relational database application may implement business logic in stored procedures, SQL subqueries, bulk update queries, and aggregation queries.	queried efficiently in a limited number of ways, outside of which queries can be expensive and slow. Writes to DynamoDB are singletons. Application business logic that formerly ran in stored procedures must be refactored to run outside of DynamoDB in custom code running on a host such as Amazon Amazon EC2 or AWS Lambda.
Designing the database	You design for flexibility without worrying about implementation details or performance. Query optimization generally doesn't affect schema design, but normalization is important.	You design your schema specifically to make the most common and important queries as fast and as inexpensive as possible. Your data structures are tailored to the specific requirements of your business use cases.

Designing for NoSQL database requires a different mindset than designing for a relational database management system (RDBMS). For an RDBMS, you can create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. You can organize each type of data into its own table.

With NoSQL design, you can design your schema for DynamoDB when you know the questions it'll need to answer. Understanding the business problems and the application read and write patterns is essential. You should also aim to maintain as few tables as possible in a DynamoDB application. Having fewer tables keeps things more scalable, requires less permissions management, and reduces overhead for your DynamoDB application. It can also help keep backup costs lower overall.

The task of modeling relational data for DynamoDB and building a new version of the front-end application is a separate topic. This guide assumes you have a new version of your application built to use DynamoDB, but you still need to determine how best to migrate and synchronize historical data during the cutover.

Sizing Considerations

The maximum size of each item (row) that you store in a DynamoDB table is 400KB. For more information, see the section called "Quotas". The item size is determined by the total size of all attribute names and attribute values in an item. For more information, see the section called "Item sizes and formats".

If your application needs to store more data in an item than the DynamoDB size limit permits, break the item into an item collection, compress the item data, or store the item as an object in Amazon Simple Storage Service (Amazon S3) while storing the Amazon S3 object identifier in your DynamoDB item. See the section called "Large items". The cost to update an item is based on the full size of the item. For workloads that require frequent updates to existing items, having small items of one or two KB will cost less to update than larger items. See the section called "Working with Item Collections" for more information on item collections.

When choosing the partition and sort key attributes, other table settings, item size and structure, and whether to create secondary indexes, be sure to review the DynamoDB Modeling documentation as well as the guide for the section called "Cost optimization". Be sure to test your migration plan so your DynamoDB solution is cost efficient and fits within DynamoDB's features and limitations.

Understanding how a migration to DynamoDB works

Before reviewing the migration tools available to us, consider how writes are processed by DynamoDB.

The default and most common write operation is a single `PutItem` API operation. You can perform a `PutItem` operation in a loop to process data sets. DynamoDB supports virtually unlimited concurrent connections, so assuming you can configure and run a massively multi-threaded loading routine such as MapReduce or Spark, the velocity of writes is only limited by the capacity of the target table (which is also generally unlimited).

When loading data into DynamoDB, it's important to understand your loader's write velocity. If the items (rows) you are loading are 1KB in size or less, this velocity is simply the number of items per second. The target table can then be provisioned with sufficient WCU (write capacity units) to handle this rate. If your loader exceeds the provisioned capacity in any given second, the extra requests may be throttled or rejected altogether. You can check for throttles in the CloudWatch charts found in the DynamoDB console monitoring tab.

The second operation that can be performed is with a related API called `BatchWriteItem`. `BatchWriteItem` allows you to combine up to 25 write requests into one API call. These are received by the service and processed as separate `PutItem` requests to the table. Currently, when choosing `BatchWriteItem`, you will not get the advantage of automatic retries that is included with the AWS SDK when making singleton calls with `PutItem`. So if there are any errors (such as throttling exceptions), you'll have to look for the list of any failed writes on the response call to `BatchWriteItem`. For more information on handling throttling warnings in case these are detected in the CloudWatch throttling charts, see the section called “Throttling”.

The third type of data import is possible with the DynamoDB Import from S3 feature. This feature allows you to stage a large dataset in Amazon S3 and ask DynamoDB to automatically import the data into a new table. The import is not instant and will take time proportional to the size of the dataset. However, it's convenient since it requires no ETL platform or custom DynamoDB code. DynamoDB loads the data into a new table that's created by the import. Currently, it doesn't allow you to load data into an existing table. DynamoDB imports the data as-is, with no transformations. Similar to `PutItem`, it requires an upstream process and writes the data in your chosen format to an Amazon S3 bucket.

Tools to help migrate to DynamoDB

There are several common migration and ETL tools you can use to migrate data into DynamoDB.

Amazon provides a host of data tools that can be used in migration, including AWS Database Migration Service (DMS), AWS Glue, Amazon EMR, and Amazon Managed Streaming for Apache Kafka. All of these tools can be used to perform a downtime migration, and they can leverage relational database Change Data Capture (CDC) features to support online migrations. When choosing a tool, it'll help to consider the skill set and experience your organization has with each tool along with the features, performance, and cost of each one.

Many customers choose to write their own migration scripts and jobs in order to build custom data transformations for the migration process. If you plan to operate a high volume DynamoDB

table with heavy write traffic or regular large bulk load jobs, you may wish to write migration code yourself to get more familiar with the behavior of DynamoDB under heavy write traffic. Scenarios such as throttle handling and efficient table provisioning can be experienced early in the project when performing a practice migration.

Choosing the appropriate strategy to migrate to DynamoDB

A large relational database application may span a hundred or more tables and support several different application functions. When approaching a large migration, consider breaking your application into smaller components or micro-services, and migrating a small set of tables at a time. You can then migrate additional components to DynamoDB in waves.

When selecting a migration strategy, various factors may steer you towards one solution or another. The following decision tree simplifies the options available given your requirements and resources. The concepts are briefly mentioned here (but will be covered in more depth later in the guide):

- **Offline migration**: if your application can tolerate some downtime during the migration, it'll simplify the migration process.
- **Hybrid migration**: this approach allows for partial uptime during a migration, such as allowing reads but not writes, or allowing reads and inserts but not updates and deletes.
- **Online migration**: applications that require zero downtime during migration are less easy to migrate, and can require significant planning and custom development. One key decision is to estimate and weigh the costs of building a custom migration process versus the cost to the business of having a downtime window during cutover.

If	And	Then
You're okay to take the application down for some time during a maintenance window to perform the data migration. This is an **offline migration**.		Use AWS DMS and perform an offline migration using a full load task. Pre-shape the source data with a SQL `VIEW` if desired.
You're okay to run the application in read-only mode		Disable writes within the application or source

If	And	Then
during migration. This is a **hybrid migration**.		database. Use AWS DMS and perform an offline migration using a full load task.
You're okay to run the application with reads and new record inserts, but no updates or deletes, during the migration. This is a **hybrid migration**.	You have application development skills and can update the existing relationa l app to perform dual writes including to DynamoDB, for all new records	Use AWS DMS and perform an offline migration using a full load task. Concurren tly, deploy a version of the existing app that allows reads and performs dual writes.
You require a migration with minimal downtime. This is an **online** migration.	• You're migrating source tables 1-for-1 into DynamoDB without major schema changes.	Use AWS DMS to perform an online data migration. Run a bulk load task followed by CDC sync task.
You require a migration with minimal downtime. This is an **online** migration.	• You're combining source tables into fewer DynamoDB tables following the stacked schema or single table philosophy. • You have backend database development skills and spare capacity on the SQL host.	Create the NoSQL-ready table within the SQL database. Populate and synchronize it using JOINs, UNIONs, VIEWs, triggers, stored procedures.
You require a migration with minimal downtime. This is an **online** migration.	• You're combining source tables into fewer DynamoDB tables following single table philosophy. For example: • You don't have backend database development skills and spare capacity on the SQL host.	Consider the hybrid or offline migration approaches.

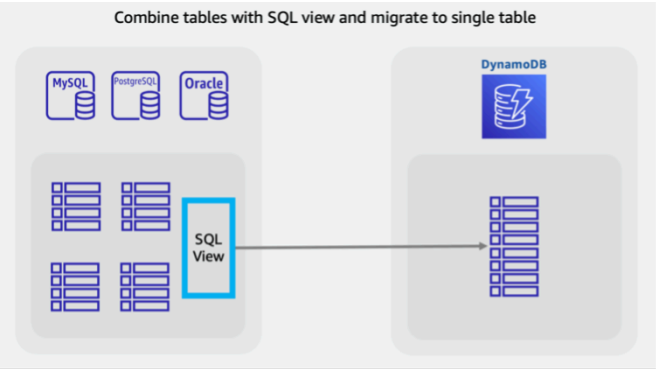
If	And	Then
You require a migration with minimal downtime. This is an **online** migration.	You're okay to skip migrating historical transaction data, or can archive it in Amazon S3 in lieu of migrating it. You just need to migrate a few small static tables.	Write a script or use any ETL tool to migrate the tables. Pre-shape the source data with a SQL `VIEW` if desired.

Performing an offline migration to DynamoDB

Offline migrations are suitable for when you can allow a downtime window to perform the migration. Relational databases commonly take at least some downtime each month for maintenance and patching, or may take longer downtimes for hardware upgrades or major release upgrades.

Amazon S3 can be used as a staging area during a migration. Data stored in CSV (comma separated values) or DynamoDB JSON format can be automatically imported into a new DynamoDB table using the DynamoDB import from S3 feature.

You may want to combine tables to leverage unique NoSQL access patterns (for example, transforming four legacy tables into a single DynamoDB table). A single key-value document request or a query for a pre-grouped item collection usually returns with better latency than a SQL database that performs a multi-table join. However, this makes the migration task more difficult. A SQL view could do the work within the source database to prepare a single dataset representing all four tables in one set.



This view can `JOIN` tables into a denormalized form, or could keep the entities normalized and stack tables using a SQL `UNION`. Key decisions around re-shaping relational data are covered in

this video. For offline migrations, using a view to combine tables is a great way to shape data for a DynamoDB single table schema.

Plan

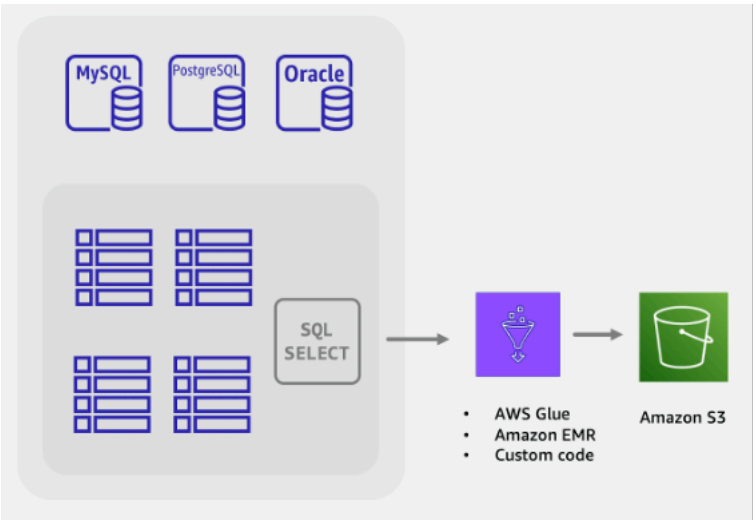
Perform an offline migration using Amazon S3

Tools

- An ETL job to extract and transform SQL data and store it in an S3 bucket such as:
  - AWS Database Migration Service, a service that can bulk load historical data and can also process Change Data Capture (CDC) records to synchronize source and target tables.
  - AWS Glue
  - Amazon EMR
  - Your own custom code
- The DynamoDB import from S3 feature

Offline migration steps:

1. Build an ETL job that can query the SQL database, transform table data into DynamoDB JSON or CSV format, and save it to an S3 bucket.



2. The DynamoDB Import from S3 feature is invoked to create a new table and automatically load data from your S3 bucket.

The fully offline migration is simple and straightforward, but it may not be popular with application owners and users. Users would benefit if the application could provide reduced levels of service during the migration, instead of no service at all.

You could add functionality to disable writes during the offline migration, while allowing reads to continue as normal. Application users could still safely browse and query for existing data while the relational data is being migrated. If this is what you're looking for, continue reading to learn about hybrid migrations.

Performing a hybrid migration to DynamoDB

While all database applications perform read and write operations, the types of write operations being performed should be considered when planning a hybrid or online migration. Database writes can be classified into three buckets: inserts, updates, and deletes. Some applications may not require immediate processing of deletions. These applications can defer deletions to a bulk cleanup process at the end of the month, for example. These types of applications can be simpler to migrate while allowing partial uptime.

Plan

Perform a hybrid online/offline migration with application dual writes

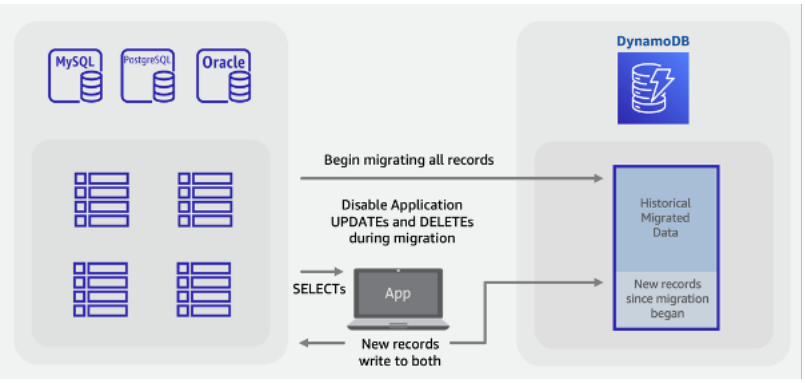
Tools

- An ETL job to extract and transform SQL data and store it in an S3 bucket such as:
  - AWS DMS
  - AWS Glue
  - Amazon EMR
  - Your own custom code

Hybrid migration steps:

1. Create the target DynamoDB table. This table will receive both historical bulk data and new, live data
2. Create a version of the legacy application that has deletes and updates disabled while performing all inserts as dual writes to both the SQL database and DynamoDB
3. Begin the ETL job or AWS DMS task to backfill existing data and deploy the new application version at the same time

4. When the backfill job completes, DynamoDB will have all existing and new records and be ready for application cutover



Note

The backfill job writes directly from SQL to DynamoDB. You can't use the S3 import feature as in the offline migration example, since that feature creates a new table that will not be live until after DynamoDB loads the data.

Performing an online migration to DynamoDB by migrating each table 1:1

Many relational databases have a feature called Change Data Capture (CDC), where the database allows users to request a list of the changes to a table that happened before or after a specific point in time. CDC uses internal logs to enable this feature and it does not require the table to have any timestamp column to work.

When migrating a schema of SQL tables to a NoSQL database, you might want to combine and reshape your data into fewer tables. Doing so will allow you to collect data in a single place and avoid having to manually join related data in multi-step read operations. However, single table data shaping is not always required and sometimes you'll migrate tables 1-for-1 into DynamoDB. These 1-to-1 table migrations are less complicated as you can leverage the source database CDC feature, using common ETL tools that support this type of migration. The data for each row may still be transformed into new formats, but the scope of each table remains the same.

Consider migrating SQL tables 1-to-1 into DynamoDB, with the caveat that DynamoDB doesn't support server-side joins. You'll need to add logic to your application to combine data from multiple tables.

Plan

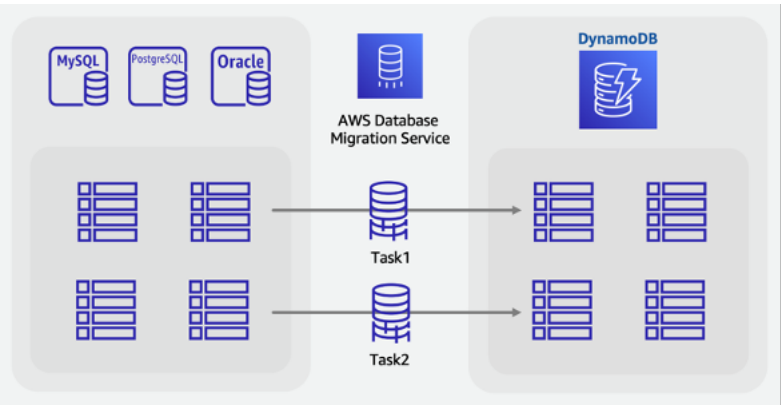
Perform an online migration of each table into DynamoDB using AWS DMS

Tools

- AWS DMS (DMS)

Online migration steps:

1. Identify the tables in your source schema that will be migrated
2. Create the same number of tables in DynamoDB with the same key structure as in the source
3. Create a replication server in AWS DMS and configure the source and target endpoints
4. Define any per-row transformations required (such as concatenated columns or conversion of dates to ISO-8601 string format)
5. Create a migration task for each table for **Full Load and Change Data Capture**
6. Monitor these tasks until the ongoing replication phase has begun
7. At this point you may perform any validation audits and then switch users to the application that reads and writes to DynamoDB



Perform an online migration to DynamoDB using a custom staging table

Like in the offline migration scenario above, you can choose to combine tables to leverage unique NoSQL access patterns (for example, transforming four legacy tables into one single DynamoDB table). A SQL `VIEW` could do the work within the source database to prepare a single dataset representing all four tables in one set.

However, for online migrations with live, changing data, you are unable to leverage CDC features as they aren't supported for `VIEW`s. If your tables include a last-updated timestamp column, and these are incorporated these into the `VIEW`, you can then build a custom ETL job that uses these to achieve a bulk load with synchronization.

A novel approach to this challenge is to use standard SQL features such as views, stored procedures, and triggers to create a new SQL table that is in the final desired DynamoDB NoSQL format.

If your database server has the spare capacity, it's possible to create this single staging table before migration begins. You would do this by writing a stored procedure that will read from existing tables, transform data as needed, and write to the new staging table. You can add a set of triggers to replicate changes in tables into the staging table in real time. If triggers are not allowed per company policy, changes to stored procedures can accomplish the same result. You would add a few lines of code to any procedure that writes data, to additionally write the same changes into the staging table.

Having this staging table in place that is fully synchronized with the legacy application tables will give you a great starting point for a live migration. Tools using database CDC to accomplish live migrations, such as AWS DMS, can now be used against this table. An advantage of this approach is that it uses well-known SQL skills and features available in the relational database engine.

Plan

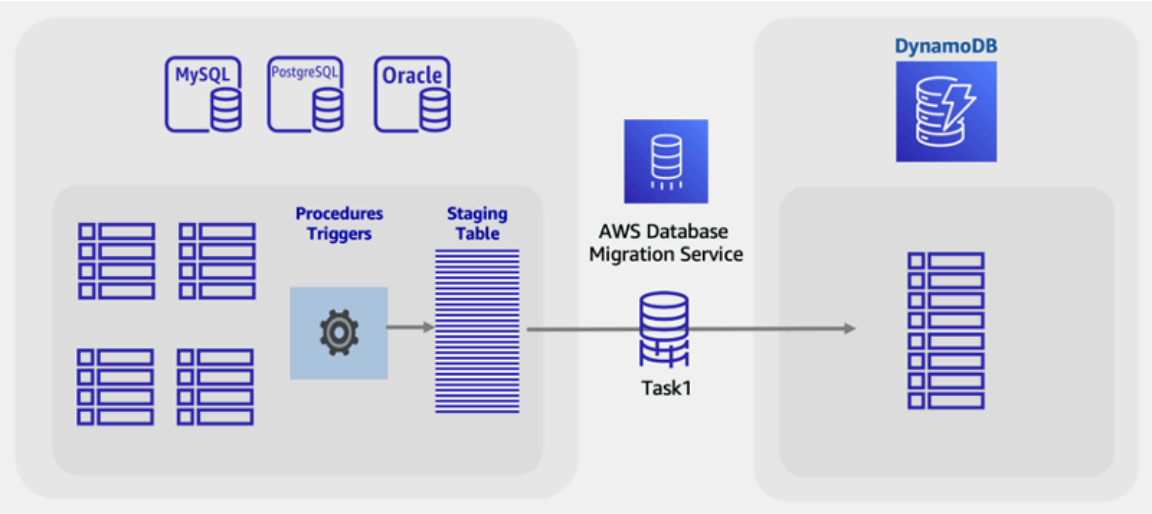
Perform an online migration with an SQL staging table using AWS DMS

Tools

- Custom SQL stored procedures or triggers
- AWS DMS

Online migration steps:

1. Within the source relational database engine, make sure there is some extra disk space and processing capacity.
2. Create a new staging table in the SQL database, with timestamps or CDC features enabled
3. Write and run a stored procedure to copy existing relational table data into the staging table
4. Deploy triggers or modify existing procedures to dual write into the new staging table while performing normal writes to existing tables
5. Run AWS DMS to migrate and synchronize this source table to a target DynamoDB table



This guide presented several considerations and approaches for migrating relational database data into DynamoDB, with a focus on minimizing downtime and using common database tools and techniques. For more information, see the following:

- AWS DMS User Guide
- AWS Glue User Guide
- Best Practices for Migrating from RDBMS to DynamoDB

NoSQL Workbench for DynamoDB

NoSQL Workbench for Amazon DynamoDB is a cross-platform, client-side GUI application that you can use for modern database development and operations. It's available for Windows, macOS, and Linux. NoSQL Workbench lets you design DynamoDB data models, define access patterns as real DynamoDB operations, and validate them using sample data. Additionally you can organize your data models into projects. NoSQL Workbench includes DynamoDB local, which makes it possible to test your tables and indexes before committing your data model to the cloud. To learn more about DynamoDB local and its requirements, see Setting up DynamoDB local (downloadable version).

Data modeler

With NoSQL Workbench for DynamoDB, you can start a new project from scratch or use a sample project that matches your use case. Then, you design tables and Global Secondary Indexes, define attributes, and configure sample data. You can also visualize your access patterns as real DynamoDB operations (PutItem, UpdateItem, Query, and others) and run these operations against the configured sample data to validate that the access pattern works as intended, making adjustments to the data model based on validation results. Finally, after validation, you commit the model to either DynamoDB local or your AWS account for further testing and production use. For collaboration, you can import and export designed data models. For more information, see Building data models with NoSQL Workbench.

Operation builder

NoSQL Workbench provides a rich graphical user interface for you to develop and test queries. You can use the *operation builder* to view, explore, and query live datasets. The structured operation builder supports projection expression, condition expression, and generates sample code in multiple languages. You can directly clone tables from one Amazon DynamoDB account to another one in different Regions. You can also directly clone tables between DynamoDB local and an Amazon DynamoDB account for faster copying of your table's key schema (and optionally GSI schema and items) between your development environments. For more information, see Exploring datasets and building operations with NoSQL Workbench.

The video below details concepts of data modeling with NoSQL Workbench.

Topics

- Download NoSQL Workbench for DynamoDB

- Building data models with NoSQL Workbench
- Exploring datasets and building operations with NoSQL Workbench
- Sample data models for NoSQL Workbench
- Release history for NoSQL Workbench

Download NoSQL Workbench for DynamoDB

Follow these instructions to download NoSQL Workbench and DynamoDB local for Amazon DynamoDB.

To download NoSQL Workbench and DynamoDB local

- Download the appropriate version of NoSQL Workbench for your operating system.

Operating system	Download link
macOS (Intel)	Download for macOS (Intel)
macOS (Apple silicon)	Download for macOS (Apple silicon)
Windows	Download for Windows
Linux	Download for Linux

Note

NoSQL Workbench includes DynamoDB local as part of the installation process. Java Runtime Environment (JRE) version 17.x or newer is required for running DynamoDB local.

Note

NoSQL Workbench supports Ubuntu 12.04, Fedora 21, and Debian 8, or any newer versions of these Linux distributions.

There are two prerequisite pieces of software required for Ubuntu installs: `libfuse2` and `curl`.
As of Ubuntu 22.04, libfuse2 is no longer installed by default. To solve this, run `sudo add-apt-repository universe && sudo apt install libfuse2` to install for the newest Ubuntu version.
For cURL, run `sudo apt update && sudo apt upgrade && sudo apt install curl`.

Building data models with NoSQL Workbench

You can use the data modeler tool in NoSQL Workbench for Amazon DynamoDB to build new data models, or to design models based on existing data models that satisfy your application data access patterns. The data modeler includes a few sample data models to help you get started.

Topics

- Creating a new data model
- Importing an existing data model
- Editing an existing data model
- Adding sample data to a data model
- Adding and validating access patterns
- Importing sample data from a CSV file
- Facets
- Viewing all tables in a data model using aggregate view
- Exporting a data model
- Committing a data model to DynamoDB

Creating a new data model

Follow these steps to create a new data model in Amazon DynamoDB using NoSQL Workbench.

To create a new data model

1. Open NoSQL Workbench, and on the main screen, choose **Create model manually**.

A new page opens with an empty configuration for your first table. NoSQL Workbench creates all new data models with a default name (for example, untitled-2) and adds them to the **Drafts** project folder.

2. On **Table configuration screen**, specify the following:

   - **Table name** — Enter a unique name for the table.
   - **Partition key** — Enter a partition key name, and specify its type. Optionally, you can also select a more granular data type format for sample data generation.
   - If you want to add a **Sort key**, specify the sort key name and its type. Optionally, you can select a more granular data type format for sample data generation.

   > **Note**
   >
   > To learn more about primary key design, designing and using partition keys effectively, and using sort keys, see the following:
   >
   > - Primary key
   > - Best practices for designing and using partition keys effectively in DynamoDB
   > - Best practices for using sort keys to organize data in DynamoDB

3. You can add other attributes to more clearly validate your model and access patterns. To add other attributes:

   - Choose **Add an attribute**.
   - Specify the attribute name and its type.
   - Optionally, you can select a more granular data type format for sample data generation.

4. If you want to add a global secondary index, choose **Add global secondary index**. Specify the **Global secondary index name**, **Partition key** attribute, and **Projection type**.

   For more information about working with global secondary indexes in DynamoDB, see Global secondary indexes.

5. Optionally, **Add a facet**. A facet is a virtual construct in NoSQL Workbench. It is not a functional construct in DynamoDB. Facets in NoSQL Workbench help you visualize an application's different data access patterns for DynamoDB with only a subset of the data in a table.

> **Note**
>
> We recommend you use Adding and validating access patterns to visualize how your application will access data in DynamoDB instead of Facets. Access patterns mirror your actual database interactions and help you build the correct data model for your use case, although facets are non-functional visualizations.

Choose **Add facet**. Specify the following:

- The **Facet name**.
- A **Partition key alias** to help distinguish this facet view.
- A **Sort key alias** if you provided a **Sort key** for the table.
- Choose the **Attributes** that are part of this facet.

Repeat this step if you want to add more facets.

6. Finally, choose **Save** to create the table.
7. If you need other **Tables** or **Global Secondary Indexes**, choose the **+** icon above the table you just created.

Importing an existing data model

You can use NoSQL Workbench for Amazon DynamoDB to build a data model by importing and modifying an existing model. You can import data models in either NoSQL Workbench model format or in AWS CloudFormation JSON template format.

To import a data model

1. Open NoSQL Workbench, and on the main screen, choose **Import model**. You can import either a NoSQL Workbench model format or CloudFormation JSON template.
2. You can add the imported model to an existing project or create a new project. If you don't choose a different project, your model is added to the drafts project folder.
3. Choose **Browse your desktop** and select a model to import from your computer.
4. After your model is imported, you can add access patterns, edit tables or indexes, and modify the data locally.

Editing an existing data model

To edit an existing model

1. To begin making changes to an existing model, open the model in the modeler page.
2. In the resource selector panel, you see the list of **Tables** and **Global Secondary Indexes**.
3. To edit a **Table** or a **Global Secondary Index**, first choose its name in the resource selector panel, and then use the action icons at the top. Available actions are **Delete**, **Duplicate**, and **Edit**.
4. If you want to edit **Model details**, choose the three-dot icon next to the model name.
5. From there, you can choose **Edit model details** and edit the information accordingly.
6. You can also **Duplicate**, **Move**, **Delete**, and **Export** the model from the same menu.
7. To change to another model, you can either go through the main screen again, or use the model selection dropdown.

Adding sample data to a data model

To auto-generate sample data

1. Open NoSQL Workbench, and on the main screen, choose the name of the model that you want to add sample data to.
2. Choose the additional actions (three-dot icon) in the main content toolbar and choose **Add sample data**.
3. Enter the number of items of sample data that you would like to generate, then choose **Confirm**.
4. Auto-generating sample data helps you generate between 1 to 5000 rows of data for immediate use. You can specify a granular sample data type to create realistic data based on your design and testing needs. To use the capability to generate realistic data, you need to specify the sample data type format for your attributes in the Data modeler. See Creating a new data model for specifying sample data type formats.

To add sample data one item at a time

1. Open the model you want to edit then choose the table you want to add sample data to. Choose the additional actions (three-dot icon) in the main content toolbar and choose **Edit data**.
2. Now you can add, delete, and edit rows. After you have made necessary changes, choose **Save**.

Adding and validating access patterns

You can use NoSQL Workbench for Amazon DynamoDB to create, store, and validate *access patterns*.

> **Note**
>
> See Identify your data access patterns for more details on identifying the right access patterns.

To create an access pattern

1. Open NoSQL Workbench, and on the main screen, choose the name of the model that you want to add access patterns to.
2. On the left side, choose the **Access patterns** tab, and choose the **+** icon.
3. On the next screen, provide a **Name**, an optional **Description**, the **Type** of the access pattern, and the **Table** or **Global Secondary Index** to test the access pattern against.

   > **Note**
   >
   > NoSQL Workbench currently supports the following operations for access patterns: `Scan`, `Query`, `GetItem`, `PutItem`, `UpdateItem`, `DeleteItem`. Amazon DynamoDB supports a broader list of operations.

4. After you create an access pattern, you can switch to the **Validate** tab to verify that your data model is designed to return expected results for the access pattern. See Adding sample data to a data model for details on how to auto-generate sample data for your tables. Different types of access patterns support different input parameters.

> **Note**
>
> To validate access patterns, NoSQL Workbench starts a separate DynamoDB local database on port `8001` (by default) with tables and indexes stored in memory.
>
> - NoSQL Workbench automatically adds the sample data from your model to the temporary tables.
> - If you edit the sample data or the data model itself, NoSQL Workbench updates the temporary tables.
> - This temporary database is erased when you close the application.

To edit your access patterns

1. Open NoSQL Workbench, and on the main screen, choose the name of the model that you want to edit access patterns for.
2. On the left side, choose the **Access patterns** tab.
3. To edit an access pattern, choose it from the list on the left.
4. In the top bar, choose **Edit**.

Importing sample data from a CSV file

If you have preexisting sample data in a CSV file, you can import it into NoSQL Workbench. This enables you to quickly populate your model with sample data without having to enter it line by line.

The column names in the CSV file must match the attribute names in your data model, but they do not need to be in the same order. For example, if your data model has attributes called `LoginAlias`, `FirstName`, and `LastName`, your CSV columns could be `LastName`, `FirstName`, and `LoginAlias`.

You can import up to 150 rows at a time from a CSV file.

To import data from a CSV file into NoSQL Workbench

1. To import CSV data to a **Table**, first choose the table name in the resource panel, and then choose the additional actions (three-dot icon) in the main content toolbar.

2. Choose **Import sample data**.
3. Choose your CSV file and choose **Open**. The CSV data appends to your table.

Facets

In NoSQL Workbench, *Facets* give you a way to view a subset of the data in a table, without having to see records that don't meet the constraints of the facet. Facets are considered a visual data modeling tool, and don't exist as a usable construct in DynamoDB, as they are purely an aid to modeling of access patterns.

> **Note**
>
> We recommend you use Adding and validating access patterns to visualize how your application will access data in DynamoDB instead of Facets. Access patterns mirror your actual database interactions and help you build the correct data model for your use case, although facets are non-functional visualizations.

To create a facet

1. In the resource selector panel, choose a **Table** you want to edit
2. In the top bar, choose **Edit**.
3. Scroll down to the **Facet filters** section.
4. Choose **Add facet**. Specify the following:

   - The **Facet name**.
   - A **Partition key alias** to help distinguish this facet view.
   - A **Sort key alias** if you provided a **Sort key** for the table.
   - Choose the **Attributes** that are part of this facet.

   Repeat this step if you want to add more facets.

Viewing all tables in a data model using aggregate view

The aggregate view in NoSQL Workbench for Amazon DynamoDB allows you to visualize all the tables and indexes in a data model. For each table, the following information appears:

- Table column names
- Sample data
- All global secondary indexes that are associated with the table. NoSQL Workbench displays the following information for each index:
  - Index column names
  - Sample data

To view all table information

1. Open NoSQL Workbench, and on the main screen, choose the name of the model that you want to open.
2. In the top bar, choose **Aggregate view**. You see the data across all tables and indexes on the same screen.

To export aggregate view as images

1. With **Aggregate view** selected, choose the three-dot icon and choose **Export aggregate view**
2. An archive with PNG images of all tables and indexes is available for download.

Exporting a data model

After you create a data model using NoSQL Workbench for Amazon DynamoDB, you can save and export the model in either NoSQL Workbench model format or AWS CloudFormation JSON template format.

To export a data model

1. Open NoSQL Workbench, and on the main screen, choose the name of the model that you want to edit.
2. Choose the three-dot icon next to the data model name and choose **Export model**.
3. Choose whether to export your data model in NoSQL Workbench model format or CloudFormation JSON template format.
   - Choose **NoSQL Workbench model** format if you want to share your model with other team members using NoSQL Workbench or import it into NoSQL Workbench later.

- Choose **CloudFormation JSON template** format if you want to deploy your model directly to AWS or integrate it into your infrastructure-as-code workflow.

Committing a data model to DynamoDB

When you are satisfied with your data model, you can commit the model to Amazon DynamoDB.

> **Note**
>
> - This action creates server-side resources in AWS for the tables and global secondary indexes represented in the data model.
> - NoSQL Workbench creates tables and indexes with on-demand capacity by default.

To commit the data model to DynamoDB

1. Open NoSQL Workbench, and on the main screen, choose the name of the model that you want to commit.
2. In the top bar, choose **Commit**.
3. Choose an existing connection, or create a new connection by choosing **Add new connection**.

   - To add a new connection, specify the following information:
     - **Account Alias**
     - **AWS Region**
     - **Access key ID**
     - **Secret access key**

     For more information about how to obtain the access keys, see Getting an AWS access key.
   - You can optionally specify the following:
     - **Session token**
     - **IAM role ARN**
4. If you prefer to use DynamoDB local:

   1. Choose the **Local connection** tab.
   2. Choose **Add new connection**.

3. Specify the **Connection name** and **Port**.

> **Note**
>
> To use DynamoDB local, turn it on by using the **DynamoDB local** toggle at the bottom left of the NoSQL Workbench screen.

5. Choose **Commit**.

Exploring datasets and building operations with NoSQL Workbench

NoSQL Workbench for Amazon DynamoDB provides a rich graphical user interface for developing and testing queries. You can use the operation builder in NoSQL Workbench to view, explore, and query live datasets. The structured operation builder supports projection expression, condition expression, and generates sample code in multiple languages. You can directly clone tables from one Amazon DynamoDB account to another one in different Regions. You can also directly clone tables between DynamoDB local and an Amazon DynamoDB account for faster copying of your table's key schema (and optionally GSI schema and items) between your development environments.You can save as many as 50 DynamoDB data operations in the operation builder.

Topics

- Connecting to live datasets
- Building complex operations
- Cloning tables with NoSQL Workbench
- Exporting data to a CSV file

Connecting to live datasets

To connect to your Amazon DynamoDB tables with NoSQL Workbench, you must first connect to your AWS account.

To add a connection to your database

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Operation builder** icon.
2. Choose **Add connection**.
3. Specify the following information:

   - **Connection name**
   - **AWS Region**
   - **Access key ID**
   - **Secret access key**

   For more information about how to obtain the access keys, see Getting an AWS access key.

   You can optionally, specify the following:

   - **Session token**
   - **IAM role ARN**
4. Choose **Connect**.

   If you don't want to sign up for a free tier account, and prefer to use DynamoDB local (downloadable version):

   a. Choose the **Local** tab on the connection screen.

   b. Specify the following information:

      - **Connection name**
      - **Port**

   c. Choose the **connect** button.

> **Note**
>
> To connect to DynamoDB local, either manually launch DynamoDB local using your terminal (see deploying DynamoDB local on your computer) or launch DynamoDB local

directly using the DDB local toggle in the NoSQL Workbench navigation menu. Ensure the connection port is the same as your DynamoDB local port.

5. On the created connection, choose **Open**.

After connecting to your DynamoDB database, the list of available tables appears in the left pane. Choose one of the tables to return a sample of the data stored in the table.

You can now run queries against the selected table.

To run queries on a table, see the next section on building operations see Building complex operations.

Building complex operations

The operation builder in NoSQL Workbench for Amazon DynamoDB provides a visual interface where you can perform complex data plane operations. It includes support for projection expressions and condition expressions. After you've built an operation, you can save it for later use (up to 50 operations can be saved). You can then browse a list of your frequently used data-plane operations in the **Saved Operations** menu, and use them to automatically populate and build a new operation. You can also generate sample code for these operations, in multiple languages.

NoSQL Workbench supports building PartiQL for DynamoDB statements, which allows you to interact with DynamoDB using a SQL-compatible query language. NoSQL Workbench also supports building DynamoDB CRUD API operations.

To use NoSQL Workbench to build operations, in the navigation pane on the left side, choose the **Operation builder** icon.

Topics

- Building PartiQL statements
- Building API operations

Building PartiQL statements

To use NoSQL Workbench to build PartiQL for DynamoDB statements, choose **PartiQL editor** near the top of the NoSQL Workbench UI.

You can build the following PartiQL statement types in the operation builder.

Topics

- Singleton statements
- Transactions
- Batch

Singleton statements

To run or generate code for a PartiQL statement, do the following.

1. Choose **PartiQL editor** near the top of the window.
2. Enter a valid PartiQL statement.
3. If your statement uses parameters:
   a. Choose **Optional request parameters**.
   b. Choose **Add new parameters**.
   c. Enter the attribute type and value.
   d. If you want to add additional parameters, repeat steps b and c.
4. If you want to generate code, choose **Generate code**.

   Select your desired language from the displayed tabs. You can now copy this code and use it in your application.
5. If you want the operation to be run immediately, choose **Run**.
6. If you want to save this operation for later use, choose **Save operation**. Then enter a name for your operation and choose **Save**.

Transactions

To run or generate code for a PartiQL transaction, do the following.

1. Choose **PartiQLTransaction** from the **More operations** dropdown.
2. Choose **Add a new statement**.
3. Enter a valid PartiQL statement.

> **Note**
>
> Read and write operations are not supported in the same PartiQL transaction request. A SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements. See Performing transactions with PartiQL for DynamoDB for more details.

4. If your statement uses parameters

   a. Choose **Optional request parameters**.

   b. Choose **Add new parameters**.

   c. Enter the attribute type and value.

   d. If you want to add additional parameters, repeat steps b and c.

5. If you want to add more statements, repeat steps 2 to 4.
6. If you want to generate code, choose **Generate code**.

   Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

7. If you want the operation to be run immediately, choose **Run**.
8. If you want to save this operation for later use, choose **Save operation**. Then enter a name for your operation and choose **Save**.

Batch

To run or generate code for a PartiQL batch, do the following.

1. Choose **PartiQLBatch** from the **More operations** dropdown.
2. Choose **Add a new statement**.
3. Enter a valid PartiQL statement.

> **Note**
>
> Read and write operations are not supported in the same PartiQL batch request, which means a SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements. Write operations to the same item are not allowed. As with the BatchGetItem operation, only singleton read operations are supported. Scan and

query operations are not supported. See Running batch operations with PartiQL for DynamoDB for more details.

4. If your statement uses parameters:

   a. Choose **Optional request parameters**.

   b. Choose **Add new parameters**.

   c. Enter the attribute type and value.

   d. If you want to add additional parameters, repeat steps b and c.

5. If you want to add more statements, repeat steps 2 to 4.

6. If you want to generate code, choose **Generate code**.

   Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

7. If you want the operation to be run immediately, choose **Run**.

8. If you want to save this operation for later use, choose **Save operation**. Then enter a name for your operation and choose **Save**.

Building API operations

To use NoSQL Workbench to build DynamoDB CRUD APIs, select **Operation builder** from the left of the NoSQL Workbench user interface.

Then select **Open** and choose a connection.

You can perform the following operations in the operation builder.

- Delete Table
- Create Table
- Update Table

- Put Item
- Update Item
- Delete Item
- Query

- Scan
- Transact Get Items
- Transact Write Items

Delete table

To run a `Delete Table` operation, do the following.

1. Find the table you want to delete from the **Tables** section.
2. Select **Delete Table** from the horizontal ellipsis menu.
3. Confirm you want to delete the table by entering the **Table name**.
4. Select **Delete**.

For more information about this operation, see Delete table in the *Amazon DynamoDB API Reference*.

Delete GSI

To run a `Delete GSI` operation, do the following.

1. Find the GSI of a table you want to delete from the **Tables** section.
2. Select **Delete GSI** from the horizontal ellipsis menu.
3. Confirm you want to delete the GSI by entering the **GSI name**.
4. Select **Delete**.

For more information about this operation, see Delete table in the *Amazon DynamoDB API Reference*.

Create table

To run a `Create Table` operation, do the following.

1. Choose the **+** icon next to the **Tables** section.
2. Enter the table name desired.
3. Create a partition key.
4. Optional: create a sort key.

5. To customize capacity settings, and uncheck the box next to **Use default capacity settings**.
   - You can now select either **Provisioned** or **On-demand capacity.**

     With Provisioned selected, you can set minimum and maximum read and write capacity units. You can also enable or disable auto scaling.
   - If the table is currently set to On-demand, you will be unable to specify a provisioned throughput.
   - If you switch from On-demand to Provisioned throughput, then Autoscaling will automatically be applied to all GSIs with: min: 1, max: 10; target: 70%.
6. Select **Skip GSIs and create** to create this table without a GSI. Optionally, you can select **Next** to create a GSI with this new table.

For more information about this operation, see Create table in the *Amazon DynamoDB API Reference*.

Create GSI

To run a `Create GSI` operation, do the following.

1. Find a table that you want to add a GSI to.
2. From the horizontal ellipsis menu, select **Create GSI**.
3. Name your GSI under **Index name**.
4. Create a partition key.
5. Optional: create a sort key.
6. Choose a projection type option from the dropdown.
7. Select **Create GSI**.

For more information about this operation, see Create table in the *Amazon DynamoDB API Reference*.

Update table

To update capacity settings for a table with an `Update Table` operation, do the following.

1. Find the table you want to update capacity settings for.
2. From the horizontal ellipsis menu, select **Update capacity settings**.

3. Select either **Provisioned** or **On-demand capacity.**

   With **Provisioned** selected, you can set minimum and maximum read and write capacity units. You can also enable or disable auto scaling.

4. Select **Update**.

For more information about this operation, see Update table in the *Amazon DynamoDB API Reference*.

Update GSI

To update capacity settings for a GSI with an `Update Table` operation, do the following.

> **Note**
>
> By default, global secondary indexes inherit the capacity settings of the base table. Global secondary indexes can have a different capacity mode only when the base table is in provisioned capacity mode. When you create a global secondary index on a provisioned mode table, you must specify read and write capacity units for the expected workload on that index. For more information, see Provisioned throughput considerations for Global Secondary Indexes.

1. Find the GSI you want to update capacity settings for.
2. From the horizontal ellipsis menu, select **Update capacity settings**.
3. You can now select either **Provisioned** or **On-demand capacity.**

   With **Provisioned** selected, you can set minimum and maximum read and write capacity units. You can also enable or disable auto scaling.

4. Select **Update**.

For more information about this operation, see Update table in the *Amazon DynamoDB API Reference*.

Put item

You create an item by using the `Put Item` operation. To run or generate code for a `Put Item` operation, do the following.

1. Find the table you want to create an item in.
2. From the **Actions** dropdown, select **Create item**.
3. Enter the partition key value.
4. Enter the sort key value, if one exists.
5. If you want to add non-key attributes, do the following:

   a. Select **+ Add other attributes**.

   b. Specify the **Attribute name**, **Type**, and **Value**.
6. If a condition expression must be satisfied for the `Put Item` operation to succeed, do the following:

   a. Choose **Condition**.

   b. Specify the attribute name, comparison operator, attribute type, and attribute value.

   c. If other conditions are needed, choose **Condition** again.

   For more information, see DynamoDB condition expression CLI example.
7. If you want to generate code, choose **Generate code**.

   Select your desired language from the displayed tabs. You can now copy this code and use it in your application.
8. If you want the operation to be run immediately, choose **Run**.
9. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see PutItem in the *Amazon DynamoDB API Reference*.

Update item

To run or generate code for an `Update Item` operation, do the following:

1. Find the table you want to update an item in.
2. Select the item.
3. Enter the attribute name and attribute value for the selected expression.
4. If you want to add more expressions, choose another expression in the **Update Expression** dropdown list, and then select the **+** icon.

5. If a condition expression must be satisfied for the `Update Item` operation to succeed, do the following:

   a. Choose **Condition**.

   b. Specify the attribute name, comparison operator, attribute type, and attribute value.

   c. If other conditions are needed, choose **Condition** again.

   For more information, see DynamoDB condition expression CLI example.

6. If you want to generate code, choose **Generate code**.

   Choose the tab for the language that you want. You can now copy this code and use it in your application.

7. If you want the operation to be run immediately, choose **Run**.

8. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see UpdateItem in the *Amazon DynamoDB API Reference*.

Delete item

To run a `Delete Item` operation, do the following.

1. Find the table you want to delete an item in.
2. Select the item.
3. From the **Actions** dropdown, select **Delete item**.
4. Confirm you want to delete the item by selecting **Delete**.

For more information about this operation, see DeleteItem in the *Amazon DynamoDB API Reference*.

Duplicate item

You can duplicate an item by creating a new item with the same attributes. To duplicate an item, do the following.

1. Find the table you want to duplicate an item in.

2. Select the item.
3. From the **Actions** dropdown, select **Duplicate item**.
4. Specify a new partition key.
5. Specify a new sort key (if necessary).
6. Select **Run**.

For more information about this operation, see DeleteItem in the *Amazon DynamoDB API Reference*.

Query

To run or generate code for a `Query` operation, do the following.

1. Select **Query** from the top of the NoSQL Workbench UI.
2. Specify the partition key value.
3. If a sort key is needed for the `Query` operation:
   a. Select **Sort key**.
   b. Specify the comparison operator, and attribute value.
4. Select **Query** to run this query operation. If more options are needed, check the **More options** checkbox and continue on with the following steps.
5. If not all the attributes should be returned with the operation result, select **Projection expression**.
6. Choose the **+** icon.
7. Enter the attribute to return with the query result.
8. If more attributes are needed, choose the **+** .
9. If a condition expression must be satisfied for the `Query` operation to succeed, do the following:
   a. Choose **Condition**.
   b. Specify the attribute name, comparison operator, attribute type, and attribute value.
   c. If other conditions are needed, choose **Condition** again.

   For more information, see DynamoDB condition expression CLI example.

10. If you want to generate code, choose **Generate code**.

    Choose the tab for the language that you want. You can now copy this code and use it in your application.

11. If you want the operation to be run immediately, choose **Run**.
12. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see Query in the *Amazon DynamoDB API Reference*.

Scan

To run or generate code for a `Scan` operation, do the following.

1. Select **Scan** from the top of the NoSQL Workbench UI.
2. Select the **Scan** button to perform this basic scan operation. If more options are needed, check the **More options** checkbox and continue on with the following steps.
3. Specify an attribute name to filter your scan results.
4. If not all the attributes should be returned with the operation result, select **Projection expression**.
5. If a condition expression must be satisfied for the scan operation to succeed, do the following:

    a. Choose **Condition**.

    b. Specify the attribute name, comparison operator, attribute type, and attribute value.

    c. If other conditions are needed, choose **Condition** again.

    For more information, see DynamoDB condition expression CLI example.

6. If you want to generate code, choose **Generate code**.

    Choose the tab for the language that you want. You can now copy this code and use it in your application.

7. If you want the operation to be run immediately, choose **Run**.
8. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

TransactGetItems

To run or generate code for a `TransactGetItems` operation, do the following.

1. From the **More operations** dropdown at the top of the NoSQL Workbench UI, choose **TransactGetItems**.
2. Choose the **+** icon near **TransactGetItem**.
3. Specify a partition key.
4. Specify a sort key (if necessary).
5. Select **Run** to perform the operation, **Save operation** to save it, or **Generate code** to generate code for it.

For more information about transactions, see Amazon DynamoDB transactions.

TransactWriteItems

To run or generate code for a `TransactWriteItems` operation, do the following.

1. From the **More operations** dropdown at the top of the NoSQL Workbench UI, choose **TransactWriteItems**.
2. Choose an operation from the **Actions** dropdown.
3. Choose the **+** icon near **TransactWriteItem**.
4. In the **Actions** dropdown, choose the operation that you want to perform.

   - For `DeleteItem`, follow the instructions for the Delete item operation.
   - For `PutItem`, follow the instructions for the Put item operation.
   - For `UpdateItem`, follow the instructions for the Update item operation.

   To change the order of actions, choose an action in the list on the left side, and then choose the up or down arrows to move it up or down in the list.

   To delete an action, choose the action in the list, and then choose the **Delete** (trash can) icon.
5. Select **Run** to perform the operation, **Save operation** to save it, or **Generate code** to generate code for it.

For more information about transactions, see Amazon DynamoDB transactions.

Cloning tables with NoSQL Workbench

Cloning tables will copy a table's key schema (and optionally GSI schema and items) between your development environments. You can clone a table between DynamoDB local to an Amazon DynamoDB account, and even clone a table from one account to another in different Regions for faster experimentation.

To clone a table

1. In the **Operation Builder**, select your connection and Region (Region selection is not available for DynamoDB local).
2. After you are connected to DynamoDB, browse your tables and select the table you want to clone.
3. From the horizontal ellipsis menu, select the **Clone** option.
4. Input your clone destination details:
    a. Select a connection.
    b. Select a Region (Region is not available for DynamoDB local).
    c. Enter a new table name.
    d. Choose a clone option:
        i. **Key schema** is selected by default and cannot be unselected. By default, cloning a table will copy your primary key and sort key if they are available.
        ii. **GSI schema** is selected by default if your table to be cloned has a GSI. Cloning a table will copy your GSI primary key and sort key if they are available. You have the option to deselect GSI schema to skip cloning the GSI schema. Cloning a table will copy your base table's capacity settings as the GSI's capacity settings. You can use the `UpdateTable` operation in Operation Builder to update the table's GSI capacity setting after cloning is complete.
5. Enter the number of items to clone. To only clone the key schema and optionally the GSI schema, you can keep the **Items to clone** value at 0. The maximum number of items that can be cloned is 5000.
6. Choose a capacity mode:

a. **On-demand mode** is selected by default. DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you pay only for what you use. To learn more, see DynamoDB On-demand mode .

b. **Provisioned mode** lets you specify the number of reads and writes per second that you require for your application. You can use auto scaling to adjust your table's provisioned capacity automatically in response to traffic changes. To learn more, see DynamoDB Provisioned mode.

7. Select **Clone** to begin cloning.
8. The cloning process will run in the background. The **Operation builder** tab will show a notification when there is a change in the cloning table status. You can access this status by selecting the **Operation builder** tab and then selecting the arrow button. The arrow button is located on the cloning table status widget located near the bottom of the menu sidebar.

Exporting data to a CSV file

You can export the results of a query from Operation Builder to a CSV file. This enables you to load the data into a spreadsheet or process it using your preferred programming language.

Exporting to CSV

1. In the Operation Builder, run an operation of your choice, such as a Scan or Query.

> **Note**
>
> - You can only export results from read API operations and PartiQL statements to a CSV file. You can't export results from transaction read statements.
> - Currently, you can export results one page at a time to a CSV file. If there are multiple pages of results, you must export each page individually.

2. Select the items you want to export from the results.
3. In the **Actions** dropdown, choose **Export as CSV**.
4. Choose a filename and location for your CSV file and select **Save**.

Sample data models for NoSQL Workbench

The home page for the modeler displays a number of sample models that ship with the NoSQL Workbench. This section describes these models and their potential uses.

Topics

- Employee data model
- Discussion forum data model
- Music library data model
- Ski resort data model
- Credit card offers data model
- Bookmarks data model

Employee data model

This data model is an introductory model. It represents an employee's basic details such as a unique alias, first name, last name, designation, manager, and skills.

This data model depicts a few techniques such as handling complex attribute such as having more than one skill. This model is also an example of one-to-many relationship through the manager and their reporting employees that has been achieved by the secondary index DirectReports.

The access patterns facilitated by this data model are:

- Retrieval of an employee record using the employee's login alias, facilitated by a table called `Employee`.
- Search for employees by name, facilitated by the Employee table's global secondary index called `Name`.
- Retrieval of all direct reports of a manager using the manager's login alias, facilitated by the Employee table's global secondary index called `DirectReports`.

Discussion forum data model

This data model represents a discussion forums. Using this model customers can engage with the developer community, ask questions, and respond to other customers' posts. Each AWS service has

a dedicated forum. Anyone can start a new discussion thread by posting a message in a forum, and each thread receives any number of replies.

The access patterns facilitated by this data model are:

- Retrieval of a forum record using the forum's name, facilitated by a table called `Forum`.
- Retrieval of a specific thread or all threads for a forum, facilitated by a table called `Thread`.
- Search for replies using the posting user's email address, facilitated by the Reply table's global secondary index called `PostedBy-Message-Index`.

Music library data model

This data model represents a music library that has a large collection of songs and showcases its most downloaded songs in near-real time.

The access patterns facilitated by this data model are:

- Retrieval of a song record, facilitated by a table called `Songs`.
- Retrieval of a specific download record or all download records for a song, facilitated by a table called `Songs`.
- Retrieval of a specific monthly download count record or all monthly download count records for a song, facilitated by a table called Song.
- Retrieval of all records (including song record, download records, and monthly download count records) for a song, facilitated by a table called `Songs`.
- Search for most downloaded songs, facilitated by the Songs table's global secondary index called `DownloadsByMonth`.

Ski resort data model

This data model represents a ski resort that has a large collection of data for each ski lift collected daily.

The access patterns facilitated by this data model are:

- Retrieval of all data for a given ski lift or overall resort, dynamic and static, facilitated by a table called `SkiLifts`.

- Retrieval of all dynamic data (including unique lift riders, snow coverage, avalanche danger, and lift status) for a ski lift or the overall resort on a specific date, facilitated by a table called `SkiLifts`.
- Retrieval of all static data (including if the lift is for experienced riders only, vertical feet the lift rises, and lift riding time) for a specific ski lift, facilitated by a table called `SkiLifts`.
- Retrieval of date of data recorded for a specific ski lift or the overall resort sorted by total unique riders, facilitated by the SkiLifts table's global secondary index called `SkiLiftsByRiders`.

Credit card offers data model

This data model is used by a Credit Card Offers Application.

A credit card provider produces offers over time. These offers include balance transfers without fees, increased credit limits, lower interest rates, cash back, and airline miles. After a customer accepts or declines these offers, the respective offer status is updated accordingly.

The access patterns facilitated by this data model are:

- Retrieval of account records using `AccountId`, as facilitated by the main table.
- Retrieval of all the accounts with few projected items, as facilitated by the secondary index `AccountIndex`.
- Retrieval of accounts and all the offer records associated with those accounts by using `AccountId`, as facilitated by the main table.
- Retrieval of accounts and specific offer records associated with those accounts by using `AccountId` and `OfferId`, as facilitated by the main table.
- Retrieval of all `ACCEPTED/DECLINED` offer records of specific `OfferType` associated with accounts using `AccountId`, `OfferType`, and `Status`, as facilitated by the secondary index `GSI1`.
- Retrieval of offers and associated offer item records using `OfferId`, as facilitated by the main table.

Bookmarks data model

This data model is used store bookmarks for customers.

A customer can have many bookmarks and a bookmark can belong to many customers. This data model represents a many-to-many relationship.

The access patterns facilitated by this data model are:

- A single query by `customerId` can now return customer data as well as bookmarks.
- A query `ByEmail` index returns customer data by email address. Note that bookmarks are not retrieved by this index.
- A query `ByUrl` index gets bookmarks data by URL. Note that this index has customerId as the sort key because the same URL can be bookmarked by multiple customers.
- A query `ByCustomerFolder` index gets bookmarks by folder for each customer.

Release history for NoSQL Workbench

The following table describes the important changes in each release of the *NoSQL Workbench* client tool.

Version	Change	Description	Date
3.20.2	Bug fixes	Improved error handling when DynamoDB local fails to start or is canceled, and fixes to the Data Modeler for DynamoDB access patterns.	April 6, 2026
3.20.1	Maintenance release	Stability and release configuration fixes.	February 17, 2026
3.20.0	New Data Modeler for DynamoDB	Data Modeler for DynamoDB has an updated user experience. Data Modeler for DynamoDB now	February 16, 2026

Version	Change	Description	Date
		supports access patterns.	
3.13.5	Capacity mode for default table settings is now on-demand	When you create a table with default settings, DynamoDB creates a table that uses on-demand capacity mode instead of provision ed capacity mode.	February 24, 2025
3.13.0	NoSQL Workbench operation builder improvements	NoSQL Workbench now includes native support for dark mode. Improved table and item operations in the operations builder. Item results and operation builder request information is available in JSON format.	April 24, 2024

Version	Change	Description	Date
3.12.0	Cloning tables with NoSQL Workbench and returning capacity consumed	You can now clone tables between DynamoDB local and a DynamoDB web service account or between DynamoDB web service accounts for faster developme nt iterations. View RCU or WCU consumed after running an operation using the Operations Builder. We fixed the overwrite data issue when importing from a CSV file.	February 26, 2024
3.11.0	DynamoDB local improvements	You can now specify port when launching the built-in DynamoDB local instance. NoSQL Workbench can now be installed on Windows without admin rights. We have updated the data model templates.	January 17, 2024

Version	Change	Description	Date
3.10.0	Native support for Apple silicon	NoSQL Workbench now includes native support for Mac with Apple silicon. You can now configure sample data generation format for attributes of type `Number`.	December 5, 2023
3.9.0	Data modeler improvements	Visualizer now supports committin g data models to DynamoDB local with the option to overwrite existing tables.	November 3, 2023
3.8.0	Sample data generation	NoSQL Workbench now supports generating sample data for your DynamoDB data models.	September 25, 2023
3.6.0	Improvements in the Operations builder	Connections management improvements in the Operations builder. Attribute names in Data Modeler can now be changed without deleting data. Other bug fixes.	April 11, 2023

Version	Change	Description	Date
3.5.0	Support for new AWS Regions	NoSQL Workbench now supports the ap-south-2, ap-southeast-3, ap-southeast-4, eu-central-2, eu-south-2, me-central-1, and me-west-1 regions.	February 23, 2023
3.4.0	Support for DynamoDB local	NoSQL Workbench now supports installing DynamoDB local as part of the installation process.	December 6, 2022
3.3.0	Support for control plane operations	Operation Builder now supports control plane operations.	June 1, 2022
3.2.0	CSV import and export	You can now import sample data from a CSV file in the Visualizer tool, and also export the results of an Operation Builder query to a CSV file.	October 11, 2021
3.1.0	Save operations	The Operation Builder in NoSQL Workbench now supports saving operations for later use.	July 12, 2021

Version	Change	Description	Date
3.0.0	Capacity settings and CloudFormation import/export	NoSQL Workbench for Amazon DynamoDB now supports specifying a read/write capacity mode for tables, and can now import and export data models in CloudFormation format.	April 21, 2021
2.2.0	Support for PartiQL	NoSQL Workbench for Amazon DynamoDB adds support for building PartiQL statements for DynamoDB.	December 4, 2020
1.1.0	Support for Linux.	NoSQL Workbench for Amazon DynamoDB is supported on Linux—Ubuntu, Fedora, and Debian.	May 4, 2020
1.0.0	NoSQL Workbench for Amazon DynamoDB – GA.	NoSQL Workbench for Amazon DynamoDB is generally available.	March 2, 2020

Version	Change	Description	Date
0.4.1	Support for IAM roles and temporary security credentials.	NoSQL Workbench for Amazon DynamoDB adds support for AWS Identity and Access Management (IAM) roles and temporary security credentials.	December 19, 2019
0.3.1	Support for DynamoDB local (Downloadable Version).	The NoSQL Workbench now supports connecting to DynamoDB local (Downloadable Version) to design, create, query, and manage DynamoDB tables.	November 8, 2019
0.2.1	NoSQL Workbench preview released.	This is the initial release of NoSQL Workbench for DynamoDB. Use NoSQL Workbench to design, create, query, and manage DynamoDB tables.	September 16, 2019

Backup and restore for DynamoDB

DynamoDB offers on-demand backups and point-in-time recovery (PITR) backups to help protect your DynamoDB data from disaster events and offers data archiving for long-term retention. You can back up tables from a few megabytes to hundreds of terabytes of data, with no impact on performance and availability to your production applications. All backups are automatically encrypted, cataloged, and easily discoverable.

With on-demand backups, you can create a snapshot backup of your table that DynamoDB stores and manages. You're charged based on the size and duration of your backups. Using on-demand backup, you can restore your entire DynamoDB table to the exact state it was in when the backup was created.

There are two options for creating and managing DynamoDB on-demand backups:

- DynamoDB
- AWS Backup

You can use the DynamoDB on-demand backup capability to create full backups of your tables for long-term retention, and archiving for regulatory compliance needs. You can back up and restore your table data anytime from the AWS Management Console or with a single API call.

Point-in-time recovery (PITR) backups are fully managed by DynamoDB and provide up to 35 days of recovery points at a per second granularity. To use point-in-time recovery, which are continuous backups, enable point-in-time recovery (PITR) on your DynamoDB table. You get charged based on the size of your DynamoDB table for the duration you have PITR enabled on the table. Enabling Point-in-Time Recovery (PITR) on your DynamoDB table continuously backs up your data. This helps you restore your table to a specific point in time within the PITR recovery period by creating a new DynamoDB table with the exact state of your original table at that point in time.

Point-in-time recovery helps protect your DynamoDB tables from accidental write or delete operations. With point-in-time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For example, suppose that a test script writes accidentally to a production DynamoDB table.

With point-in-time recovery, you can restore your table to any point in time during the last 35 days. You can set the recovery period to any value between 1 and 35 days. After you enable point-in-

time recovery, you can restore to any point in time from five minutes before the current time until the configured recovery period. DynamoDB maintains incremental backups of your table.

In addition, point-in-time operations don't affect performance or API latencies.

You can restore a DynamoDB table to a point in time using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API. The point-in-time recovery process restores to a new table.

For more information about AWS Region availability and pricing, see Amazon DynamoDB pricing.

Note

- Tagging and attribute-based access control (ABAC) aren't supported for DynamoDB backups. To use ABAC with backups, we recommend that you use AWS Backup.
- Tags aren't preserved in restored tables. You need to add tags to restored tables before you can use tag-based conditions in your policies.

The following video will give you an introductory look at the backup and restore concept and talk more about point-in-time recovery.

Backup and restore

Topics

- Choosing your disaster recovery strategy for Amazon DynamoDB workloads

Point-in-time backups for DynamoDB

Amazon DynamoDB point-in-time recovery (PITR) provides automatic continuous backups of your DynamoDB table data. Point-in-time recovery (PITR) backups are fully managed by DynamoDB and

provide up to 35 days of recovery points at a per second granularity. With point-in-time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. This section provides an overview of how the process works in DynamoDB.

Before you begin

Before you enable point-in-time recovery (PITR) on an Amazon DynamoDB table, consider the following:

- Setting the `RecoveryPeriodinDays` allows you to shorten the time period for which continuous backups are taken. By default, your `RecoveryPeriodinDays` is 35. However, you can set it to be any value between 1 and 35. Shortening the `RecoveryPeriodinDays` has no impact on PITR pricing because the price is based on the size of table and local secondary indexes.
- If you disable point-in-time recovery and later re-enable it on a table, you reset the start time for which you can recover that table. As a result, you can only immediately restore that table using the `LatestRestorableDateTime`.
- You can enable point-in-time recovery on each local replica of a global table. When you restore the table, the backup restores to an independent table that is not part of the global table. If you are using Global Tables version 2019.11.21 (Current) of global tables, you can create a new global table from the restored table. For more information, see How DynamoDB global tables work.
- You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the source table resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data you transfer out of the source Region and for restoring to a new table in the destination Region.
- AWS CloudTrail logs all console and API actions for point-in-time recovery to enable logging, continuous monitoring, and auditing. For more information, see Logging DynamoDB operations by using AWS CloudTrail.

Topics

- Enable point-in-time recovery in DynamoDB

Enable point-in-time recovery in DynamoDB

Amazon DynamoDB point-in-time recovery (PITR) provides automatic backups of your DynamoDB table data. This section provides an overview of how the process works in DynamoDB.

> **Note**
>
> DynamoDB charges for PITR based on the size of each DynamoDB table, including table data and local secondary indexes. Changing the recovery window (for example, from 35 days to 1 day) doesn't reduce the price. The cost remains the same regardless of the recovery period you choose. The configured maximum recovery period doesn't impact the price you're charged for turning on PITR. To determine your backup charges, DynamoDB continuously monitors the size of the tables that have PITR turned on. You're billed for PITR usage until you turn off PITR for each table.

Topics

- Enabling point-in-time recovery
- Enable PITR (console)
- Enable PITR (AWS CLI)
- Enable PITR (CloudFormation)
- Enable PITR (API)
- Recovery Period
- Edit PITR
- Delete a table with PITR enabled

Enabling point-in-time recovery

You can enable point-in-time recovery using the AWS Management Console, AWS Command Line Interface (AWS CLI), or the DynamoDB API. When enabled, point-in-time recovery provides continuous backups until you explicitly turn it off.

After you enable point-in-time recovery, you can restore to any point in time within `EarliestRestorableDateTime` and `LatestRestorableDateTime`. `LatestRestorableDateTime` is typically five minutes before the current time. For more information, see Restoring a DynamoDB table to a point in time.

> **Note**
>
> The point-in-time recovery process always restores to a new table.

Enable PITR (console)

To enable PITR using the DynamoDB console

1. Navigate to the DynamoDB console.
2. Choose **Tables** from the left navigation and select your DynamoDB table.
3. From the **Backups** tab, for the **Point in Time Recovery** option, choose **Edit**.
4. Choose **Turn on point-in-time recovery**.
5. Choose a value between 1 and 35 for your backup recovery period. This indicates the maximum time period for which the continuous backup is recoverable.

Enable PITR (AWS CLI)

> **Note**
>
> If you receive errors when running AWS CLI commands, see Troubleshoot AWS CLI errors. Make sure you're using the most recent AWS CLI version.

Run the update-continuous-backups command with the **point-in-time-recovery-specification** setting turned on:

```
aws dynamodb update-continuous-backups \
--table-name Music \
--point-in-time-recovery-specification
 PointInTimeRecoveryEnabled=true,RecoveryPeriodInDays=35
```

Enable PITR (CloudFormation)

Use the AWS::DynamoDB::Table resource with the `PointInTimeRecoverySpecification` property turned on:

```
Resources:
  iotCatalog:
    Type: AWS::DynamoDB::Table
      Properties:
      ...
      PointInTimeRecoverySpecification:
        PointInTimeRecoveryEnabled: true
        RecoveryPeriodInDays: 35
```

Request syntax example:

```
{
   "PointInTimeRecoverySpecification": {
      "PointInTimeRecoveryEnabled": boolean,
      "RecoveryPeriodInDays: number
   },
   "TableName": "string"
}
```

Enable PITR (API)

Run the UpdateContinuousBackups API operation with the `PointInTimeRecoverySpecification` parameter turned on.

Request syntax example:

```
{
   "PointInTimeRecoverySpecification": {
      "PointInTimeRecoveryEnabled": boolean,
      "RecoveryPeriodInDays" : number
   },
   "TableName": "string"
}
```

Response syntax example:

```
{
   "ContinuousBackupsDescription": {
      "ContinuousBackupsStatus": "string",
      "PointInTimeRecoveryDescription": {
```

```
            "PointInTimeRecoveryStatus": "string",
            "EarliestRestorableDateTime": number,
            "RecoveryPeriodInDays": number,
            "LatestRestorableDateTime": number
        }
    }
}
```

> **Note**
>
> `ContinuousBackupsStatus` is always `ENABLED` for a DynamoDB table and can't be disabled. An `ENABLED` value doesn't mean that point-in-time recovery is turned on. Whether you can restore the table to a point in time is controlled separately by `PointInTimeRecoveryStatus`, which is `DISABLED` by default until you enable PITR. A newly created table therefore reports `ContinuousBackupsStatus` as `ENABLED` together with `PointInTimeRecoveryStatus` as `DISABLED`.

Python

```
import boto3

dynamodb = boto3.client('dynamodb')

response = dynamodb.update_continuous_backups(
    TableName=<table_name>,
    PointInTimeRecoverySpecification={
        'PointInTimeRecoveryEnabled': True,
        'RecoveryPeriodInDays': 35
    }
)
```

Recovery Period

You can set the recovery period for continuous backups to be any number between 1 and 35 days. This `RecoveryPeriodInDays` determines the time period for which your continuous backups are maintained. For example, if you set this value to be 30 days, you'll only have the ability to restore your table to any point in time from the past 30 days.

> **Note**
>
> DynamoDB charges for PITR based on the size of each DynamoDB table, including table data and local secondary indexes. The configured maximum recovery period doesn't impact the price you're charged for turning on PITR. For details on pricing, see DynamoDB pricing.

Edit PITR

You can edit the PITR setting on your table and change the recovery period. If you change the recovery period and increase it to a value higher than previously set, your `EarliestRestorePoint` will not change immediately. Since the recovery period is a rolling window, DynamoDB will continue to take automatic backups until the new increased period is reached. If you change the recovery period and decrease it to a value lower than previously set, your `EarliestRestorePoint` will immediately decrease to match your recovery period, and any continuous backups that fall outside of the new set value will not be recoverable.

Delete a table with PITR enabled

When you delete a table that has point-in-time recovery enabled, DynamoDB automatically creates a backup snapshot called a *system backup* and retains it for 35 days (at no additional cost). You can use the system backup to restore the deleted table to the state it was in before deletion. All system backups follow a standard naming convention of *`table-name`*`$DeletedTableBackup`.

> **Note**
>
> Once a table with point-in-time recovery enabled is deleted, you can use system backup to restore that table to a single point in time. The system backup will be created upon table deletion, and is a snapshot of the table right before the table is deleted.

Using on-demand DynamoDB backup and restore

Amazon DynamoDB supports stand-alone on-demand backup and restore features. Those features are available to you independent of whether you use AWS Backup.

You can use the DynamoDB on-demand backup capability to create full backups of your tables for long-term retention and archival for regulatory compliance needs. You can back up and restore

your table data anytime with a single click on the AWS Management Console or with a single API call. Backup and restore actions run with zero impact on table performance or availability.

You can create table backups using the console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API. For more information, see Backing up a DynamoDB table.

For information about restoring a table from a backup, see Restoring a DynamoDB table from a backup.

Backing up and restoring DynamoDB tables with DynamoDB: How it works

You can use the DynamoDB on-demand backup feature to create full backups of your Amazon DynamoDB tables. This feature is available independently from AWS backup. This section provides an overview of what happens during the DynamoDB backup and restore process.

Backups

When you create an on-demand backup with DynamoDB, a time marker of the request is cataloged. The backup is created asynchronously by applying all changes until the time of the request to the last full table snapshot. DynamoDB backup requests are processed instantaneously and become available for restore within minutes.

> **Note**
>
> Each time you create an on-demand backup, the entire table data is backed up. There is no limit to the number of on-demand backups that can be taken.

All backups in DynamoDB work without consuming any provisioned throughput on the table.

DynamoDB backups do not guarantee causal consistency across items; however, the skew between updates in a backup is usually much less than a second.

While a backup is in progress, you can't do the following:

- Pause or cancel the backup operation.
- Delete the source table of the backup.

- Disable backups on a table if a backup for that table is in progress.

If you don't want to create scheduling scripts and cleanup jobs, you can use AWS Backup to create backup plans with schedules and retention policies for your DynamoDB tables. AWS Backup runs the backups and deletes them when they expire. For more information, see the AWS Backup Developer Guide.

In addition to AWS Backup, you can schedule periodic or future backups by using AWS Lambda functions. For more information, see the blog post A serverless solution to schedule your Amazon DynamoDB On-Demand backup.

If you're using the console, any backups created using AWS Backup are listed on the **Backups** tab with the **Backup type** set to `AWS_BACKUP`.

> **Note**
>
> You can't delete backups marked with a **Backup type** of `AWS_BACKUP` using the DynamoDB console. To manage these backups, use the AWS Backup console.

To learn how to perform a backup, see Backing up a DynamoDB table.

Restores

You restore a table without consuming any provisioned throughput on the table. You can do a full table restore from your DynamoDB backup, or you can configure the destination table settings. When you do a restore, you can change the following table settings:

- Global secondary indexes (GSIs)
- Local secondary indexes (LSIs)
- Billing mode
- Provisioned read and write capacity
- Encryption settings

> **Important**
>
> When you do a full table restore, the destination table is set with the same provisioned read capacity units and write capacity units as the source table, as recorded at the time the

backup was requested. The restore process also restores the local secondary indexes and the global secondary indexes.

You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the backup resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data that you transfer out of the source Region and for restoring to a new table in the destination Region.

Restores can be faster and more cost-efficient if you choose to exclude some or all secondary indexes from being created on the new restored table.

You must manually set up the following on the restored table:

- Auto scaling policies
- AWS Identity and Access Management (IAM) policies
- Amazon CloudWatch metrics and alarms
- Tags
- Stream settings
- Time to Live (TTL) settings
- Deletion protection settings
- Point in time recovery (PITR) settings

You can only restore the entire table data to a new table from a backup. You can write to the restored table only after it becomes active.

Note

You can't overwrite an existing table during a restore operation.

Restore times are directly related to the configuration of your tables (such as the size of your tables and the number of underlying partitions) and other related variables. A best practice when planning for disaster recovery is to regularly document average restore completion times and establish how these times affect your overall Recovery Time Objective.

To learn how to perform a restore, see Restoring a DynamoDB table from a backup.

You can use IAM policies for access control. For more information, see Using IAM with DynamoDB backup and restore.

All backup and restore console and API actions are captured and recorded in AWS CloudTrail for logging, continuous monitoring, and auditing.

Backing up a DynamoDB table

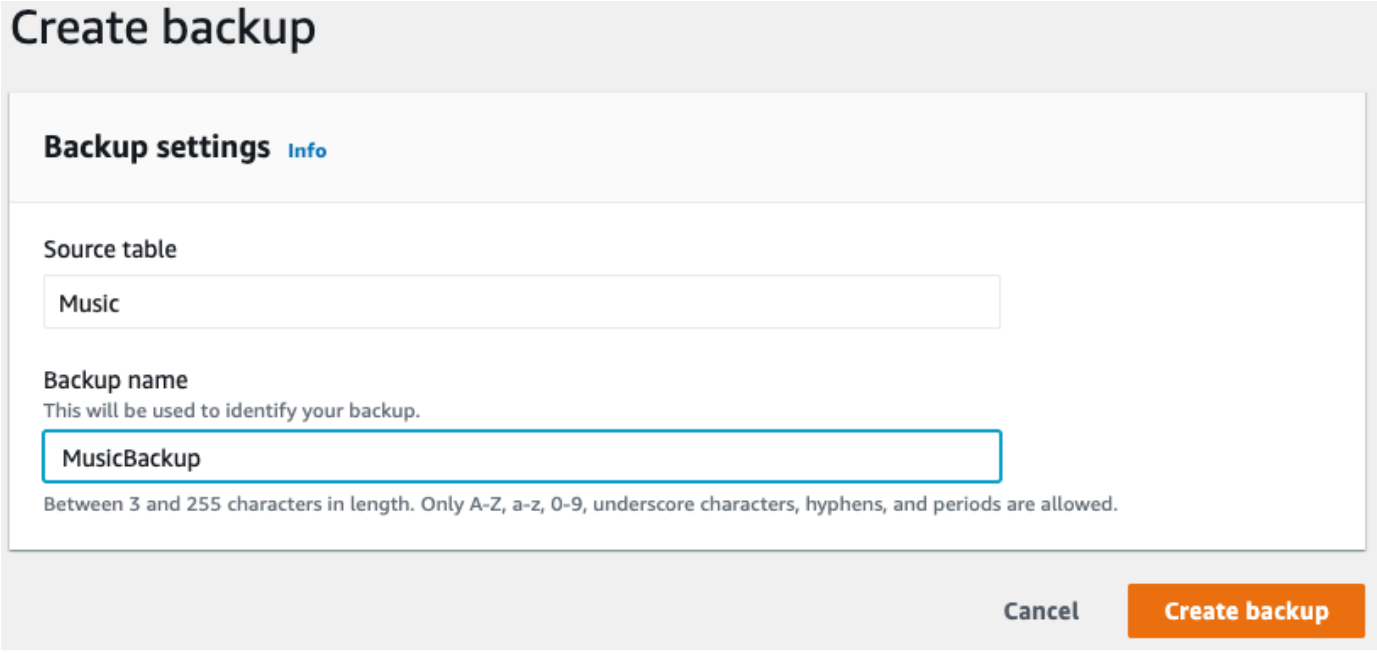
This section describes how to use the Amazon DynamoDB console or the AWS Command Line Interface to back up a table.

Creating a table backup (console)

Follow these steps to create a backup named `MusicBackup` for an existing `Music` table using the AWS Management Console.

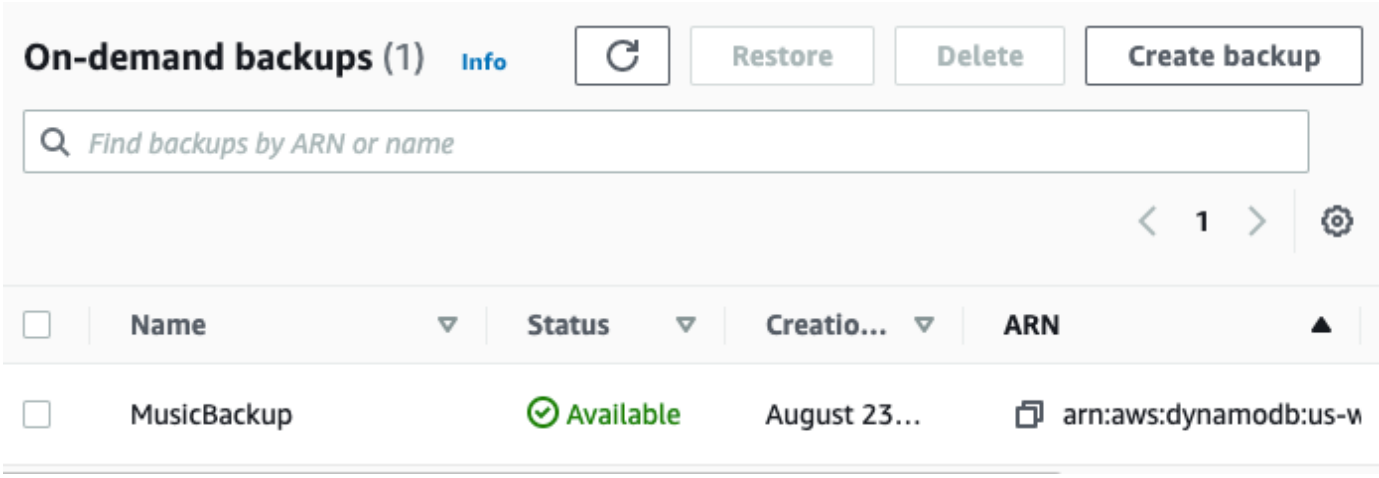
To create a table backup

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. You can create a backup by doing one of the following:
   - On the **Backups** tab of the `Music` table, choose **Create backup**.
   - In the navigation pane on the left side of the console, choose **Backups**. Then choose **Create backup**.
3. Make sure that `Music` is the table name, and enter **`MusicBackup`** for the backup name. Then, choose **Create backup** to create the backup.



> **Note**
>
> If you create backups using the **Backups** section in the navigation pane, the table isn't preselected for you. You have to manually choose the source table name for the backup.

While the backup is being created, the backup status is set to **Creating**. After the backup is complete, the backup status changes to **Available**.



Creating a table backup (AWS CLI)

Follow these steps to create a backup for an existing table `Music` using the AWS CLI.

To create a table backup

- Create a backup with the name `MusicBackup` for the `Music` table.

```
aws dynamodb create-backup --table-name Music \
 --backup-name MusicBackup
```

While the backup is being created, the backup status is set to `CREATING`.

```
{
    "BackupDetails": {
        "BackupName": "MusicBackup",
        "BackupArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489602797149-73d8d5bc",
        "BackupStatus": "CREATING",
        "BackupCreationDateTime": 1489602797.149
    }
}
```

After the backup is complete, its `BackupStatus` should change to `AVAILABLE`. To confirm this, use the `describe-backup` command. You can get the input value of `backup-arn` from the output of the previous step or by using the `list-backups` command.

```
aws dynamodb describe-backup \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489173575360-
b308cd7d
```

To keep track of your backups, you can use the `list-backups` command. It lists all your backups that are in `CREATING` or `AVAILABLE` status.

```
aws dynamodb list-backups
```

The `list-backups` command and the `describe-backup` command are useful to check information about the source table of the backup.

Restoring a DynamoDB table from a backup

This section describes how to restore a table from a backup using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

> **Note**
>
> If you want to use the AWS CLI, you must configure it first. For more information, see Accessing DynamoDB.

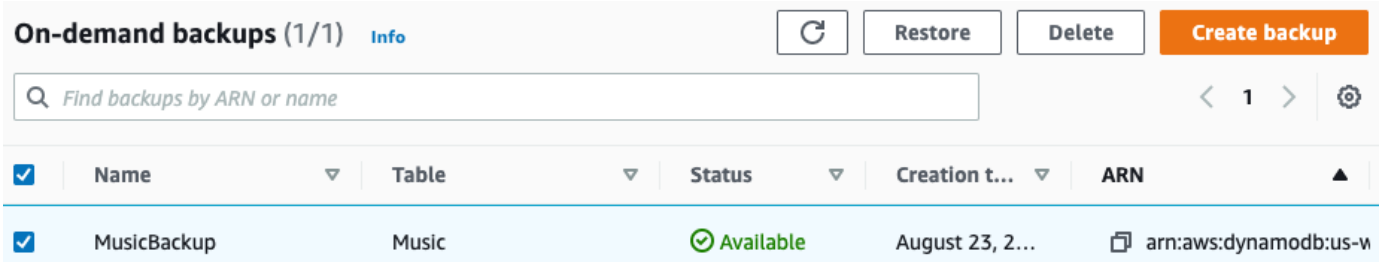
Restoring a table from a backup (console)

The following procedure shows how to restore the `Music` table by using the `MusicBackup` file that is created in the Backing up a DynamoDB table tutorial.

> **Note**
>
> This procedure assumes that the `Music` table no longer exists before restoring it using the `MusicBackup` file.

To restore a table from a backup

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the list of backups, choose `MusicBackup`.



4. Choose **Restore**.
5. Enter **`Music`** as the new table name. Confirm the backup name and other backup details. Then choose **Restore table** to start the restore process.

Note

You can restore the table to the same AWS Region or to a different Region from where the backup resides. You can also exclude secondary indexes from being created on the new restored table. In addition, you can specify a different encryption mode.
Tables restored from backups are always created using the DynamoDB Standard table class.

Restore table from backup Info

Restoring a table from a backup will restore it as a new table.

Restore settings

Name of restored table

This name will identify your restored table.

Music

Between 3 and 255 characters in length. Only A–Z, a–z, 0–9, underscore characters, hyphens, and periods allowed.

Secondary indexes

- (●) Restore the entire table
  Your restored table will include all local and global secondary indexes.
- ( ) Restore the table without secondary indexes
  Your restored table will exclude all local and global secondary indexes. Restoring this way can be faster and more cost efficient.

Destination AWS Region

- (●) Same Region (Oregon)
  Restore the table to the same Region as the original table.
- ( ) Cross-Region
  Restore the table to a different Region for greater redundancy but with higher data transfer costs.

▼ Encryption at rest - *optional*

All user data stored in Amazon DynamoDB is fully encrypted at rest. By default, Amazon DynamoDB manages the encryption key, and you are not charged any fee for using it.

Encryption key management Info

- (●) Owned by Amazon DynamoDB
  The key is owned and managed by DynamoDB. You are not charged an additional fee for using this customer master key (CMK).
- ( ) AWS managed CMK
  The key is stored in your account and is managed by AWS Key Management Service (AWS KMS). AWS KMS charges apply.
- ( ) Stored in your account, and owned and managed by you
  Choose a key that is owned and managed by you, and stored in AWS KMS.

ⓘ The time it takes to restore a table from a backup can vary and is based on multiple variables. After your table is restored from the backup, you might need to reapply configuration settings. Learn more

Cancel Restore

The table that is being restored is shown with the status **Creating**. After the restore process is finished, the status of the `Music` table changes to **Active**.

Restoring a table from a backup (AWS CLI)

Follow these steps to use the AWS CLI to restore the `Music` table using the `MusicBackup` that is created in the Backing up a DynamoDB table tutorial.

To restore a table from a backup

1. Confirm the backup that you want to restore by using the `list-backups` command. This example uses `MusicBackup`.

   ```
   aws dynamodb list-backups
   ```

   To get additional details for the backup, use the `describe-backup` command. You can get the input `backup-arn` from the previous step.

   ```
   aws dynamodb describe-backup \
   --backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
   backup/01489173575360-b308cd7d
   ```

2. Restore the table from the backup. In this case, the `MusicBackup` restores the `Music` table to the same AWS Region.

   ```
   aws dynamodb restore-table-from-backup \
   --target-table-name Music \
   --backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
   backup/01489173575360-b308cd7d
   ```

3. Restore the table from the backup with custom table settings. In this case, the `MusicBackup` restores the `Music` table and specifies an encryption mode for the restored table.

   > **Note**
   >
   > The `sse-specification-override` parameter takes the same values as the `sse-specification-override` parameter used in the `CreateTable` command. To learn more, see Managing encrypted tables in DynamoDB.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01581080476474-e177ebe2 \
--sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-
abcd-1234-a123-ab1234a1b234
```

You can restore the table to a different AWS Region from where the backup resides.

Note

- The `sse-specification-override` parameter is mandatory for cross-Region restores but optional for restores in the same Region as the source table.
- When performing a cross-Region restore from the command line, you must set the default AWS Region to the desired destination Region. To learn more, see Command line options in the *AWS Command Line Interface User Guide*.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01581080476474-e177ebe2 \
--sse-specification-override Enabled=true,SSEType=KMS
```

You can override the billing mode and the provisioned throughput for the restored table.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489173575360-b308cd7d \
--billing-mode-override PAY_PER_REQUEST
```

You can exclude some or all secondary indexes from being created on the restored table.

> **Note**
>
> Restores can be faster and more cost-efficient if you exclude some or all secondary indexes from being created on the restored table.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01581081403719-db9c1f91 \
--global-secondary-index-override '[]' \
--sse-specification-override Enabled=true,SSEType=KMS
```

> **Note**
>
> The secondary indexes provided should match existing indexes. You cannot create new indexes at the time of restore.

You can use a combination of different overrides. For example, you can use a single global secondary index and change provisioned throughput at the same time, as follows.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:eu-west-1:123456789012:table/Music/
backup/01581082594992-303b6239 \
--billing-mode-override PROVISIONED \
--provisioned-throughput-override ReadCapacityUnits=100,WriteCapacityUnits=100 \
--global-secondary-index-override IndexName=singers-
index,KeySchema=["{AttributeName=SingerName,KeyType=HASH}"],Projection="{ProjectionType=KEYS_
 \
--sse-specification-override Enabled=true,SSEType=KMS
```

To verify the restore, use the `describe-table` command to describe the `Music` table.

```
aws dynamodb describe-table --table-name Music
```

The table that is being restored from the backup is shown with the status **Creating**. After the restore process is finished, the status of the `Music` table changes to **Active**.

> **Important**
>
> While a restore is in progress, don't modify or delete your IAM role policy; otherwise, unexpected behavior can result. For example, suppose that you removed write permissions for a table while that table is being restored. In this case, the underlying `RestoreTableFromBackup` operation would not be able to write any of the restored data to the table.
> After the restore operation is complete, you can modify or delete your IAM role policy.
> IAM policies involving source IP restrictions for accessing the target restore table should have the `aws:ViaAWSService` key set to `false` to make sure that the restrictions apply only to requests made directly by a principal. Otherwise, the restore will be canceled.
> If your backup is encrypted with an AWS managed key or a customer managed key, don't disable or delete the key while a restore is in progress, or the restore will fail.
> After the restore operation is complete, you can change the encryption key for the restored table and disable or delete the old key.

Deleting a DynamoDB table backup

This section describes how to use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to delete an Amazon DynamoDB table backup.

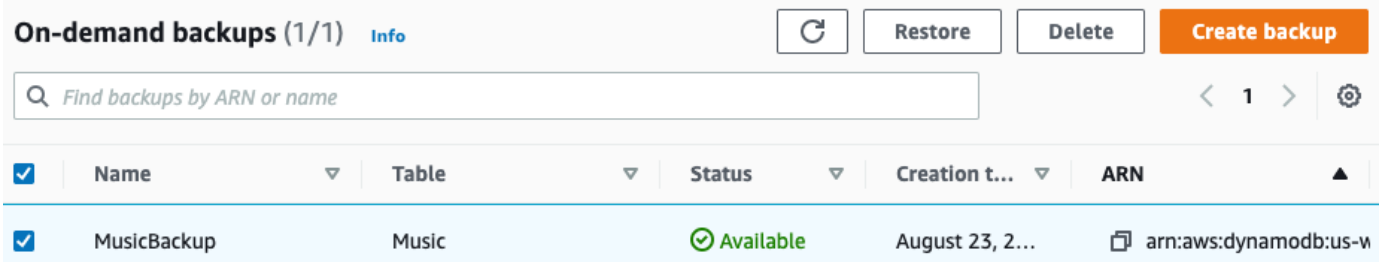
> **Note**
>
> If you want to use the AWS CLI, you have to configure it first. For more information, see Using the AWS CLI.

Deleting a table backup (console)

The following procedure shows how to use the console to delete the `MusicBackup` that is created in the Backing up a DynamoDB table tutorial.

To delete a backup

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the list of backups, choose `MusicBackup`.



4. Choose **Delete**. Confirm that you want to delete the backup by typing **`delete`** and choosing **Delete**.

Deleting a table backup (AWS CLI)

The following example deletes a backup for an existing table `Music` table using the AWS CLI.

```
aws dynamodb delete-backup \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489602797149-73d8d5bc
```

Using IAM with DynamoDB backup and restore

You can use AWS Identity and Access Management (IAM) to restrict Amazon DynamoDB backup and restore actions for some resources. The `CreateBackup` and `RestoreTableFromBackup` APIs operate on a per-table basis.

For more information about using IAM policies in DynamoDB, see Identity-based policies for DynamoDB.

The following are examples of IAM policies that you can use to configure specific backup and restore functionality in DynamoDB.

Example 1: Allow the CreateBackup and RestoreTableFromBackup actions

The following IAM policy grants permissions to allow the `CreateBackup` and `RestoreTableFromBackup` DynamoDB actions on all tables:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:CreateBackup",
                "dynamodb:RestoreTableFromBackup",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:GetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:BatchWriteItem"
            ],
            "Resource": "*"
        }
    ]
}
```

Important

DynamoDB RestoreTableFromBackup permissions are necessary on the source backup, and DynamoDB read and write permissions on the target table are necessary for restore functionality.
DynamoDB RestoreTableToPointInTime permissions are necessary on the source table, and DynamoDB read and write permissions on the target table are necessary for restore functionality.

Example 2: Allow CreateBackup and deny RestoreTableFromBackup

The following IAM policy grants permissions for the `CreateBackup` action and denies the `RestoreTableFromBackup` action:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:CreateBackup"],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": ["dynamodb:RestoreTableFromBackup"],
            "Resource": "*"
        }

    ]
}
```

Example 3: Allow ListBackups and deny CreateBackup and RestoreTableFromBackup

The following IAM policy grants permissions for the `ListBackups` action and denies the `CreateBackup` and `RestoreTableFromBackup` actions:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:ListBackups"],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:CreateBackup",
                "dynamodb:RestoreTableFromBackup"
```

```
            ],
            "Resource": "*"
        }

    ]
}
```

Example 4: Allow ListBackups and deny DeleteBackup

The following IAM policy grants permissions for the `ListBackups` action and denies the `DeleteBackup` action:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:ListBackups"],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": ["dynamodb:DeleteBackup"],
            "Resource": "*"
        }

    ]
}
```

Example 5: Allow RestoreTableFromBackup and DescribeBackup for all resources and deny DeleteBackup for a specific backup

The following IAM policy grants permissions for the `RestoreTableFromBackup` and `DescribeBackup` actions and denies the `DeleteBackup` action for a specific backup resource:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeBackup",
                "dynamodb:RestoreTableFromBackup"
            ],
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489173575360-b308cd7d"
        },
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:GetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:BatchWriteItem"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:DeleteBackup"
            ],
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489173575360-b308cd7d"
        }
    ]
}
```

Important

DynamoDB RestoreTableFromBackup permissions are necessary on the source backup, and DynamoDB read and write permissions on the target table are necessary for restore functionality.
DynamoDB RestoreTableToPointInTime permissions are necessary on the source table, and DynamoDB read and write permissions on the target table are necessary for restore functionality.

Example 6: Allow CreateBackup for a specific table

The following IAM policy grants permissions for the `CreateBackup` action on the `Movies` table only:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:CreateBackup"],
            "Resource": [
                "arn:aws:dynamodb:us-east-1:123456789012:table/Movies"
            ]
        }
    ]
}
```

Example 7: Allow ListBackups

The following IAM policy grants permissions for the `ListBackups` action:

JSON

```
{
    "Version":"2012-10-17",
```

```
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:ListBackups"],
            "Resource": "*"
        }
    ]
}
```

> **Important**
>
> You can't grant permissions for the `ListBackups` action on a specific table.

Example 8: Allow access to AWS Backup features

You will need API permissions for the `StartAwsBackupJob` action for a successful backup with advanced features, and the `dynamodb:RestoreTableFromAwsBackup` action to successfully restore that backup.

The following IAM policy grants AWS Backup the permissions to trigger backups with advanced features and restores. Also note that if the tables are encrypted the policy will need access to the AWS KMS key.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DescribeQueryScanBooksTable",
            "Effect": "Allow",
            "Action": [
                "dynamodb:StartAwsBackupJob",
                "dynamodb:DescribeTable",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:111122223333:table/Books"
        },
```

```
        {
            "Sid": "AllowRestoreFromAwsBackup",
            "Effect": "Allow",
            "Action": [
                "dynamodb:RestoreTableFromAwsBackup"
            ],
            "Resource": "*"
        }
    ]
}
```

Example 9: Deny RestoreTableToPointInTime for a Specific Source Table

The following IAM policy denies permissions for the `RestoreTableToPointInTime` action for a specific source table:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:RestoreTableToPointInTime"
            ],
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music"
        }
    ]
}
```

Example 10: Deny RestoreTableFromBackup for all Backups for a Specific Source Table

The following IAM policy denies permissions for the `RestoreTableToPointInTime` action for all backups for a specific source table:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:RestoreTableFromBackup"
            ],
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/*"
        }
    ]
}
```

Understanding Amazon DynamoDB billing for backups

This guide provides details about how DynamoDB billing works for backups. The following sections break down the various components that contribute to the overall cost, providing clear explanations and practical examples.

DynamoDB offers on-demand backups and point-in-time recovery (PITR) backups to help protect your DynamoDB data from disaster events and offers data archiving for long-term retention.

How it works

DynamoDB on-demand backups are billed monthly. If you take a backup on any particular day of the month, you'll see a single charge for that backup calculated for the remaining days of the month (example: creating a backup on the 27th, you will only be charged for the few days remaining in that month, applied as a single charge on the 27th).

If you retain your previously taken backups for subsequent months, you'll always see a full month's charge for that backup applied on the 1st. If the backup is removed before the month's end, the charges will be adjusted based on actual usage.

As an example, if you created a backup on July 27th, and it is maintained through the month of August, you will see the following charges for that backup:

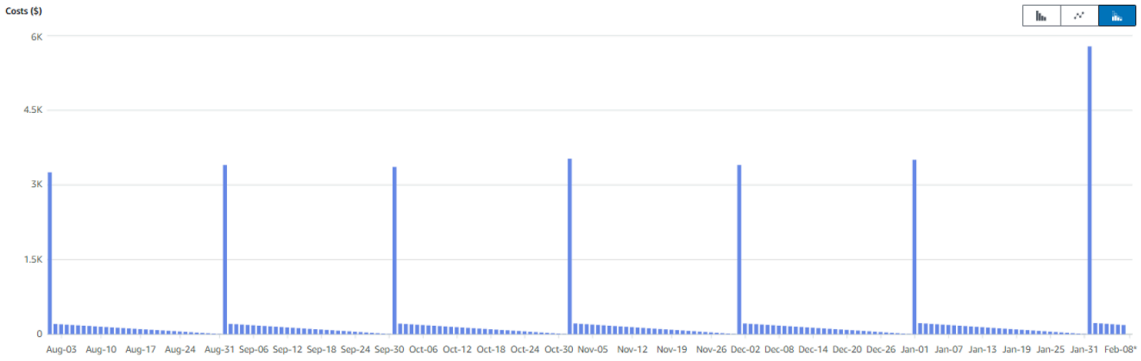
- A charge on July 27th for the remaining days of July
- A charge on August 1st for the entire month of August
- A charge on the 1st of every subsequent month that backup exists

When backups are maintained for DynamoDB tables, you may observe that the expense for the `DynamoDB (Region)-TimedBackupStorage-ByteHrs` usage metric seems abnormally high on the 1st of the month. In addition, if you check this metric at the start of a new month and compare it against previous billing cycles, you may observe what appears to be a large spike in usage. This is by design. On the 1st of every month, any existing DynamoDB backups will have usage charges for the entire month applied. Any DynamoDB backups that are removed during the month will have their usage expense prorated to reflect actual usage. As a result, you may see the charge (applied on the 1st) decrease throughout the month. This is because retention policies apply expirations or manual deletions to carried over backups occur. This will be explored in a scenario below.

Similarly, you'll notice smaller spikes throughout the month as new backups are created, with their charges applied on the day of creation for the remainder of the month.

DynamoDB backup billing example

Here is an example of what you may see in Cost Explorer at the start of the month:



Notice how February 1st appears to have a much larger spike relative to previous months. Let's break down why this occurs.

From the DynamoDB Pricing Page:

"The total backup storage size billed each month is the sum of all backups of DynamoDB tables. DynamoDB monitors the size of on-demand backups continuously throughout the month to determine your backup charges."

This explains why the bill consistently shows a large spike in usage on the 1st of every month. Any existing backups coming into a new month have a full month's charges applied to the 1st. Put another way, if you enter the month with 300 DynamoDB backups, you will see a full month's usage charges applied on the 1st day of the month for all 300 backups.

New backups taken throughout the month will incur usage charges from the day of creation until the end of the month.

What if the backup is deleted mid-month?

Here are a few scenarios to consider:

1. If a backup from the previous month is deleted on the 15th of the current month, the usage charges for that backup,still applied on the 1st, will be adjusted to the actual usage instead of the assumed full month of usage previously applied. The example below explains this more in detail.
2. When you create a backup during the month, usage charges for the remainder of the month are applied to the day it was created. However, if you delete this backup before the month ends, your usage charges will be adjusted to include only the days the backup was active, still applied on its creation date.

Why does the current month's usage appear to be so much higher on the 1st than previous months, and what happens if I remove the backups?

To answer this important 2-part question, let's set up an example scenario using the following information:

- **Length of Month**: 30 Days
- **DynamoDB Backup Frequency**: 10/day, 300/mo
- **DynamoDB Backup Retention Policy**: 30 Days
- **DynamoDB Per-Backup Cost**: $2/day, $60/mo
- **Previous 1st of Month Total** (`TimedBackupStorage-ByteHrs`, checked on the 1st of the Current Month): $9,300
- **Previous Month Total** (`TimedBackupStorage-ByteHrs`): $18,600
- **Current 1st of Month Total** (`TimedBackupStorage-ByteHrs`, Checked on the 1st): $18,000
- **Changes in DynamoDB Usage Month-to-Month**: None

Using the information above, you can see that 300 backups were created in the previous month with a policy to maintain them for 30 days. On the 1st of a new month, all of these backups still remain as they've not yet hit the end of their recovery period. However, with each passing day, the oldest sets of backups will begin to drop off, as shown here:

DynamoDB backup dropoff table

New month	Day 1	Day 2	Day 3	Day 4	Day 5
Total previous month backups carried over	300	290	280	270	260

- On the 1st, there are 300 backups @ $60/mo per backup, totaling $18,000 of `TimedBackupStorage-ByteHrs` applied. This is in contrast to the previous month, where the entire month's total was $18,600.
- On the 2nd, 10 of those backups will have expired and drop off. When this occurs, the applied charge for those backups will be adjusted to **Actual Usage** instead of **Assumed Usage**. This results in those 10 backups, previously with an applied charge on the 1st of $600 (10 Backups x 30 Days) being adjusted down to $20 (10 Backups x 1 Day).
- The following day, the next block of 10 will expire and drop, shifting their usage from 30 days down to 2 days, reducing their charge to $40 (10 Backups x 2 Days).

With every passing day, you notice that larger-than-previous-month spike begins to shrink. If you expand this to cover the entire month, you can observe the following:

DynamoDB Backup Charges (1st of Month) Progression

300 backups in blocks of 10	1st	10th	20th	30th
Block 1	$600	$20	$20	$20
Block 2	$600	$40	$40	$40
Block 3	$600	$60	$60	$60

300 backups in blocks of 10	1st	10th	20th	30th
Block 4	$600	$80	$80	$80
Block 5	$600	$100	$100	$100
Block 6	$600	$120	$120	$120
Block 7	$600	$140	$140	$140
Block 8	$600	$160	$160	$160
Block 9	$600	$180	$180	$180
Block 10	$600	$600	$200	$200
Block 11	$600	$600	$220	$220
Block 12	$600	$600	$240	$240
Block 13	$600	$600	$260	$260
Block 14	$600	$600	$280	$280
Block 15	$600	$600	$300	$300
Block 16	$600	$600	$320	$320
Block 17	$600	$600	$340	$340
Block 18	$600	$600	$360	$360
Block 19	$600	$600	$380	$380
Block 20	$600	$600	$600	$400
Block 21	$600	$600	$600	$420
Block 22	$600	$600	$600	$440
Block 23	$600	$600	$600	$460

300 backups in blocks of 10	1st	10th	20th	30th
Block 24	$600	$600	$600	$480
Block 25	$600	$600	$600	$500
Block 26	$600	$600	$600	$520
Block 27	$600	$600	$600	$540
Block 28	$600	$600	$600	$560
Block 29	$600	$600	$600	$580
Block 30	$600	$600	$600	$600
1st of month total ($)	$18,000	$13,500	$10,400	$9,300

As a new block drops off each day, it has its usage adjusted to how many days it existed, versus the full month amount. As a result, by month's end the charges observed on the 1st will have dropped from the initial $18,000 down to the expected $9,300. This number, combined with the newly created backups through the month (which will have a billing table similar to the above, but reversed), will result in a monthly expense in line with last month's $18,600.

Restore a table in DynamoDB

You can restore a DynamoDB table from your PITR backup or your on-demand backups using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API. The recovery process restores to a new DynamoDB table.

Restoring a table using point-in-time recovery

You can restore your table to any point in time up till the `EarliestRestoreableDateTime`.

Important

If you disable point-in-time recovery and later enable it on a table, you reset the start time for which you can recover that table. As a result, you can only immediately restore that table using the `LatestRestorableDateTime`.

When you restore using point-in-time recovery, DynamoDB restores your table data to the state based on the selected date and time (day:hour:minute:second) to a new table. You restore a table without consuming any provisioned throughput on the table. You can do a full table restore using point-in-time recovery, or you can configure the destination table settings. You can change the following table settings on the restored table:

- Global secondary indexes (GSIs)
- Local secondary indexes (LSIs)
- Billing mode
- Provisioned read and write capacity
- Encryption settings

Important

When you do a full table restore, the destination table is set with the same provisioned read capacity units and write capacity units that the source table had when the backup was requested. For example, suppose that a table's provisioned throughput was recently lowered to 50 read capacity units and 50 write capacity units. You then restore the table's state to three weeks ago, at which time its provisioned throughput was set to 100 read capacity units and 100 write capacity units. In this case, DynamoDB restores your table data to that point in time with the provisioned throughput from that time (100 read capacity units and 100 write capacity units).

You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the source table resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US). You pay only for the data you transfer out of the source Region and for restoring to a new table in the destination Region.

> **Note**
>
> Cross-Region restore isn't supported if the source or destination Region is Asia Pacific (Hong Kong) or Middle East (Bahrain).

Restores can be faster and more cost-efficient if you exclude some or all indexes from being created on the restored table. You must manually set the following on the restored table:

- Auto scaling policies
- AWS Identity and Access Management policies
- Amazon CloudWatch Events metrics and alarms
- CloudWatch Contributor Insights settings
- Tags
- Stream settings
- Time to Live (TTL) settings
- Deletion protection settings
- Point-in-time recovery settings

The time it takes you to restore a table varies based on multiple factors and isn't always correlated with the size of the table.

Restoring a DynamoDB table to a point in time

Amazon DynamoDB point-in-time recovery (PITR) provides continuous backups of your DynamoDB table data. You can restore a table to a point in time using the DynamoDB console or the AWS Command Line Interface (AWS CLI). The point-in-time recovery process restores to a new table.

Because a restore always creates a new table, your source table stays fully available for reads and writes while the restore runs. The restore duration depends on the amount of data and the number of secondary indexes that DynamoDB rebuilds on the new table—larger tables and more indexes take longer, and no fixed completion time is guaranteed. To make a restore faster, you can exclude some or all secondary indexes from the new table.

A restore recreates the following on the new table from the source table's settings at the restore point: the table data, global secondary indexes, local secondary indexes, provisioned read and

write capacity, and encryption settings. After the restore completes, you must set up the following on the new table yourself, because a restore does not carry them over: auto scaling policies, AWS Identity and Access Management policies, CloudWatch metrics and alarms, tags, DynamoDB Streams settings, Time to Live settings, and point-in-time recovery settings.

If you want to use the AWS CLI, you must configure it first. For more information, see Accessing DynamoDB.

Topics

- Restoring a DynamoDB table to a point in time (console)
- Restoring a table to a point in time (AWS CLI)

Restoring a DynamoDB table to a point in time (console)

The following example demonstrates how to use the DynamoDB console to restore an existing table named `Music` to a point in time.

> **Note**
>
> This procedure assumes that you have enabled point-in-time recovery. To enable it for the `Music` table, on the **Backups** tab, in the **Point-in-time recovery (PITR)** section, choose **Edit** and then check the box next to **Enable point-in-time-recovery**.

To restore a table to a point in time

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. In the list of tables, choose the `Music` table.
4. On the **Backups** tab of the `Music` table, in the **Point-in-time recovery (PITR)** section, choose **Restore**.
5. For the new table name, enter **`MusicMinutesAgo`**.

> **Note**
>
> You can restore the table to the same AWS Region or to a different Region from where the source table resides. You can also exclude secondary indexes from being created on the restored table. In addition, you can specify a different encryption mode.

6. To confirm the restorable time, set the restore date and time to **Earliest**. Then choose **Restore** to start the restore process.

   The table that is being restored is shown with the status **Restoring**. After the restore process is finished, the status of the `MusicMinutesAgo` table changes to **Active**.

Restoring a table to a point in time (AWS CLI)

The following procedure shows how to use the AWS CLI to restore an existing table named `Music` to a point in time.

> **Note**
>
> This procedure assumes that you have enabled point-in-time recovery. To enable it for the `Music` table, run the following command.
>
> ```
> aws dynamodb update-continuous-backups \
>     --table-name Music \
>     --point-in-time-recovery-specification PointInTimeRecoveryEnabled=True
> ```

To restore a table to a point in time

1. Confirm that point-in-time recovery is enabled for the `Music` table by using the `describe-continuous-backups` command.

   ```
   aws dynamodb describe-continuous-backups \
       --table-name Music
   ```

   Continuous backups (automatically enabled on table creation) and point-in-time recovery are enabled.

```
{
    "ContinuousBackupsDescription": {
        "PointInTimeRecoveryDescription": {
            "PointInTimeRecoveryStatus": "ENABLED",
            "EarliestRestorableDateTime": 1519257118.0,
            "LatestRestorableDateTime": 1520018653.01
        },
        "ContinuousBackupsStatus": "ENABLED"
    }
}
```

2. Restore the table to a point in time. In this case, the `Music` table is restored to the `LatestRestorableDateTime` (~5 minutes ago) to the same AWS Region.

```
aws dynamodb restore-table-to-point-in-time \
    --source-table-name Music \
    --target-table-name MusicMinutesAgo \
    --use-latest-restorable-time
```

> **Note**
>
> You can also restore to a specific point in time. To do this, run the command using the `--restore-date-time` argument, and specify a timestamp. You can specify any point in time within the configured recovery period, which can be set to any value between 1 and 35 days. For example, the following command restores the table to the `EarliestRestorableDateTime`.
>
> ```
> aws dynamodb restore-table-to-point-in-time \
>     --source-table-name Music \
>     --target-table-name MusicEarliestRestorableDateTime \
>     --no-use-latest-restorable-time \
>     --restore-date-time 1519257118.0
> ```
>
> Specifying the `--no-use-latest-restorable-time` argument is optional when restoring to a specific point in time.

3. Restore the table to a point in time with custom table settings. In this case, the `Music` table is restored to the `LatestRestorableDateTime` (~5 minutes ago).

You can specify a different encryption mode for the restored table, as follows.

> **Note**
>
> The `sse-specification-override` parameter takes the same values as the `sse-specification-override` parameter used in the `CreateTable` command. To learn more, see Managing encrypted tables in DynamoDB.

```
aws dynamodb restore-table-to-point-in-time \
    --source-table-name Music \
    --target-table-name MusicMinutesAgo \
    --use-latest-restorable-time \
    --sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-
abcd-1234-a123-ab1234a1b234
```

You can restore the table to a different AWS Region from where the source table resides.

> **Note**
>
> - The `sse-specification-override` parameter is mandatory for cross-Region restores but optional for restores to the same Region as the source table.
> - The `source-table-arn` parameter must be provided for cross-Region restores.
> - When performing a cross-Region restore from the command line, you must set the default AWS Region to the desired destination Region. To learn more, see Command line options in the *AWS Command Line Interface User Guide*.

```
aws dynamodb restore-table-to-point-in-time \
    --source-table-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music \
    --target-table-name MusicMinutesAgo \
    --use-latest-restorable-time \
    --sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-
abcd-1234-a123-ab1234a1b234
```

You can override the billing mode and the provisioned throughput for the restored table.

```
aws dynamodb restore-table-to-point-in-time \
    --source-table-name Music \
    --target-table-name MusicMinutesAgo \
    --use-latest-restorable-time \
    --billing-mode-override PAY_PER_REQUEST
```

You can exclude some or all secondary indexes from being created on the restored table.

> **Note**
>
> Restores can be faster and more cost-efficient if you exclude some or all secondary indexes from being created on the new restored table.

```
aws dynamodb restore-table-to-point-in-time \
    --source-table-name Music \
    --target-table-name MusicMinutesAgo \
    --use-latest-restorable-time \
    --global-secondary-index-override '[]'
```

You can use a combination of different overrides. For example, you can use a single global secondary index and change provisioned throughput at the same time, as follows.

```
aws dynamodb restore-table-to-point-in-time \
    --source-table-name Music \
    --target-table-name MusicMinutesAgo \
    --billing-mode-override PROVISIONED \
    --provisioned-throughput-override ReadCapacityUnits=100,WriteCapacityUnits=100
 \
    --global-secondary-index-override IndexName=singers-
index,KeySchema=["{AttributeName=SingerName,KeyType=HASH}"],Projection="{ProjectionType=KEY
 \
    --sse-specification-override Enabled=true,SSEType=KMS \
    --use-latest-restorable-time
```

To verify the restore, use the `describe-table` command to describe the `MusicEarliestRestorableDateTime` table.

```
aws dynamodb describe-table --table-name MusicEarliestRestorableDateTime
```

The table that is being restored is shown with the status **Creating** and restore in progress as **true**. After the restore process is finished, the status of the `MusicEarliestRestorableDateTime` table changes to **Active**.

> **Important**
>
> While a restore is in progress, don't modify or delete the AWS Identity and Access Management (IAM) policies that grant the IAM entity (for example, user, group, or role) permission to perform the restore. Otherwise, unexpected behavior can result. For example, suppose that you remove write permissions for a table while that table is being restored. In this case, the underlying `RestoreTableToPointInTime` operation can't write any of the restored data to the table. IAM policies involving source IP restrictions for accessing the target restore table can similarly cause issues.
> You can modify or delete permissions only after the restore operation is completed.

Using AWS Backup with DynamoDB

Amazon DynamoDB can help you meet regulatory compliance and business continuity requirements through enhanced backup features in AWS Backup. AWS Backup is a fully managed data protection service that makes it easy to centralize and automate backups across AWS services, in the cloud, and on premises. Using this service, you can configure backup policies and monitor activity for your AWS resources in one place. To use AWS Backup, you must affirmatively opt-in. Opt-in choices apply to the specific account and AWS Region, so you might have to opt in to multiple Regions using the same account. For more information, see the AWS Backup Developer Guide.

Amazon DynamoDB is natively integrated with AWS Backup. You can use AWS Backup to schedule, copy, tag and life cycle your DynamoDB on-demand backups automatically. You can continue to view and restore these backups from the DynamoDB console. You can use the DynamoDB console, API, and AWS Command Line Interface (AWS CLI) to enable automatic backups for your DynamoDB tables.

> **Note**
>
> Any backups made through DynamoDB will remain unchanged. You will still be able to create backups through the current DynamoDB workflow.

Enhanced backup features available through AWS Backup include:

Scheduled backups - You can set up regularly scheduled backups of your DynamoDB tables using backup plans.

Cross-account and cross-Region copying - You can automatically copy your backups to another backup vault in a different AWS Region or account, which allows you to support your data protection requirements.

Cold storage tiering - You can configure your backups to implement life cycle rules to delete or transition backups to colder storage. This can help you optimize your backup costs.

Tags - You can automatically tag your backups for billing and cost allocation purposes.

Encryption – DynamoDB on-demand backups managed through AWS Backup are now stored in the AWS Backup vault. This allows you to encrypt and secure your backups by using an AWS KMS key that is independent from your DynamoDB table encryption key.

Audit backups – You can use AWS Backup Audit Manager to audit the compliance of your AWS Backup policies and to find backup activity and resources that are not yet compliant with the controls that you defined. You can also use it to automatically generate an audit trail of daily and on-demand reports for your backup governance purposes.

Secure backups using the WORM model – You can use AWS Backup Vault Lock to enable a write-once-read-many (WORM) setting for your backups. With AWS Backup Vault Lock, you can add an additional layer of defense that protects backups from inadvertent or malicious delete operations, changes to backup recovery periods, and updates to lifecycle settings. To learn more, see AWS Backup Vault Lock.

These enhanced backup features are available in all AWS Regions. To learn more about these features, see the AWS Backup Developer Guide.

Backing up and restoring DynamoDB tables with AWS Backup: How it works

You can use the on-demand backup feature to create full backups of your Amazon DynamoDB tables. This section provides an overview of what happens during the backup and restore process.

Backups

When you create an on-demand backup with AWS Backup, a time marker of the request is cataloged. The backup is created asynchronously by applying all changes until the time of the request to the last full table snapshot.

Each time you create an on-demand backup, the entire table data is backed up. There is no limit to the number of on-demand backups that can be taken.

> **Note**
>
> Unlike DynamoDB Backups, backups made with AWS Backup are not instantaneous.

While a backup is in progress, you can't do the following:

- Pause or cancel the backup operation.
- Delete the source table of the backup.
- Disable backups on a table if a backup for that table is in progress.

AWS Backup provides automated backup schedules, retention management, and lifecycle management. This removes the need for custom scripts and manual processes. AWS Backup runs

the backups and deletes them when they expire. For more information, see the AWS Backup Developer Guide.

If you're using the console, any backups created using AWS Backup are listed on the **Backups** tab with the **Backup type** set to `AWS_BACKUP`.

> **Note**
>
> You can't delete backups marked with a **Backup type** of `AWS_BACKUP` using the DynamoDB console. To manage these backups, use the AWS Backup console.

To learn how to perform a backup, see Backing up a DynamoDB table.

Restores

You restore a table without consuming any provisioned throughput on the table. You can do a full table restore from your DynamoDB backup, or you can configure the destination table settings. When you do a restore, you can change the following table settings:

- Encryption settings

> **Important**
>
> When you do a full table restore, the destination table is set with the same provisioned read capacity units and write capacity units that the source table had when the backup was requested. The restore process also restores the local secondary indexes and the global secondary indexes.

You can copy a backup of your DynamoDB table data to a different AWS Region and then restore it in that new Region. You can copy and then restore backups between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data you copy from the source Region and the data you restore to a new table in the destination Region.

AWS Backup will restore the tables with all the original indexes.

You must manually set up the following on the restored table:

- Auto scaling policies
- AWS Identity and Access Management (IAM) policies
- Amazon CloudWatch metrics and alarms
- Tags
- Stream settings
- Time to Live (TTL) settings
- Deletion protection settings
- Point in time recovery (PITR) settings

You can only restore the entire table data to a new table from a backup. You can write to the restored table only after it becomes active.

> **Note**
>
> AWS Backup restores are nondestructive. You can't overwrite an existing table during a restore operation.

Restore times are directly related to the configuration of your tables (such as the size of your tables and the number of underlying partitions) and other related variables. A best practice when planning for disaster recovery is to regularly document average restore completion times and establish how these times affect your overall Recovery Time Objective.

To learn how to perform a restore, see Restoring a DynamoDB table from a backup.

You can use IAM policies for access control. For more information, see Using IAM with DynamoDB backup and restore.

All backup and restore console and API actions are captured and recorded in AWS CloudTrail for logging, continuous monitoring, and auditing.

Creating backups of DynamoDB tables with AWS Backup

This section describes how to turn on AWS Backup to create on-demand and scheduled backups from your DynamoDB tables.

Topics

- Turning on AWS Backup features
- On-demand backups
- Scheduled backups

Turning on AWS Backup features

You must turn on AWS Backup to use it with DynamoDB.

To turn on AWS Backup, go through the following steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the Backup Settings window, choose **Turn on**.
4. A confirmation screen will appear. Choose **Turn on features**.

AWS Backup features are now available for your DynamoDB tables.

If you choose to turn off AWS Backup features after they've been turned on, follow these steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the Backup Settings window, choose **Turn off**.
4. A confirmation screen will appear. Choose **Turn off features**.

If you can't turn the AWS Backup features on or off, your AWS admin might need to perform those actions.

On-demand backups

To create an on-demand backup of a DynamoDB table, follow these steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.

3. Choose **Create backup**.
4. From the dropdown menu that appears, choose **Create an on-demand backup**.
5. To create a backup managed by AWS Backup with warm storage and other basic features, choose **Default Settings.** To create a backup that can be transitioned to cold storage, or to create a backup with DynamoDB features instead of AWS Backup, choose **Customize settings**.

   If you want to create this backup with previous DynamoDB features instead, choose **Customize settings** and then choose **Backup with DynamoDB**.
6. When you have completed the settings, choose **Create backup.**

Scheduled backups

To schedule a backup, follow these steps.

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. From the dropdown menu that appears, choose **Schedule backups with AWS Backup**.
4. You will be taken to AWS Backup to create a backup plan.

Copying a backup of a DynamoDB table with AWS Backup

You can make a copy of a current backup. You can copy backups to multiple AWS accounts or AWS Regions on demand or automatically as part of a scheduled backup plan. You can also automate a sequence of cross-account and cross-Region copies for Amazon DynamoDB Encryption Client.

Cross-Region replication is especially valuable if you have business continuity or compliance requirements to store backups a minimum distance away from your production data.

Cross-account backups are useful for securely copying your backups to one or more AWS accounts in your organization for operational or security reasons. If your original backup is inadvertently deleted, you can copy the backup from its destination account to its source account, and then start the restore. Before you can do this, you must have two accounts that belong to the same organization in the Organizations service.

Copies inherit the source backup's configuration unless you specify otherwise, with one exception: if you specify that your new copy "Never" expire. With this setting, the new copy still inherits its

source expiration date. If you want your new backup copy to be permanent, either set your source backups to never expire, or specify your new copy to expire 100 years after its creation.

> **Note**
>
> If you're copying to another account, you must first have permission from that account.

To copy a backup, do the following:

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. Select the check box next to the backup you want to copy.
   - If the backup you want to copy is grayed out, you must enable advanced features with AWS Backup. Then create a new backup. You can now copy this new backup to other Regions and accounts, and copy any other new backups going forward.
4. Choose **Copy.**
5. If you want to copy the backup to another account or Region, select the check box next to **Copy the recovery point to another destination**. Then select whether you will to copy to another Region in your account, or to a different account in a different Region.

   > **Note**
   >
   > To restore a backup to another Region or account, you must first copy the backup to that Region or account.

6. Select the desired vault the file will be copied into. You can also create a new backup vault if desired.
7. Choose **Copy backup**.

Restoring a backup of a DynamoDB table from AWS Backup

This section describes how to restore a backup of a DynamoDB table from AWS Backup.

Topics

- Restoring a DynamoDB table from AWS Backup
- Restoring a DynamoDB table to another Region or account

Restoring a DynamoDB table from AWS Backup

To restore your DynamoDB tables from AWS Backup, follow these steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/
2. In the navigation pane on the left side of the console, choose **Tables.**
3. Choose the **Backups** tab.
4. Select the check box next to the previous backup that you want to restore from.
5. Choose **Restore**. You will be taken to the **Restore table from backup** screen.
6. Enter the name for the newly restored table, the encryption that this new table will have, the key you want the restore to be encryped with, and other options.
7. When you're finished, choose **Restore.**

Restoring a DynamoDB table to another Region or account

To restore a DynamoDB table to another Region or account, you will first need to copy the backup to that new Region or account. In order to copy to another account, that account must first grant you permission. After you have copied your DynamoDB backup to the new Region or account, it can be restored with the process in the previous section.

Deleting a backup of a DynamoDB table with AWS Backup

This section describes how to delete a backup of a DynamoDB table with AWS Backup.

A DynamoDB backup created through AWS Backup features is stored in an AWS Backup vault.

In order to delete this kind of backup, do the following:

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. On the screen that follows, choose **Continue to AWS Backup**.

The AWS Backup console opens. For more information about deleting backups in the AWS Backup console, see Deleting backups in the AWS Backup Developer Guide.

For more information about AWS Backup see Backup and recovery using AWS Backup in the *AWS Prescriptive Guidance*.

Usage note differences between on-demand backups managed by AWS Backup and DynamoDB

This section describes the technical differences between on-demand backups managed by AWS Backup and DynamoDB.

AWS Backup has some different workflows and behaviors than DynamoDB. These include:

Encryption - Backups created with the AWS Backup plan are stored in an encrypted vault with a key that is managed by the AWS Backup service. The vault has access control policies for additional security.

Backup ARN - The backup files created by AWS Backup will now have an AWS Backup ARN, which could impact the user permission model. Backup resource names (ARNs) will change from `arn:aws:dynamodb` to `arn:aws:backup`.

Deleting backups - Backups that are created with AWS Backup can only be deleted from the AWS Backup vault. You will not be able to delete AWS Backup files from the DynamoDB console.

Backup process - Unlike DynamoDB backups, backups made with AWS Backup are not instantaneous.

Billing - Backups of DynamoDB tables with AWS Backup features are billed from AWS Backup.

IAM roles - If you're managing access through IAM roles, you will also need to configure a new IAM role with these new permissions:

```
"dynamodb:StartAwsBackupJob",
"dynamodb:RestoreTableFromAwsBackup"
```

`dynamodb:StartAwsBackupJob` is needed for a successful backup with AWS Backup features, and `dynamodb:RestoreTableFromAwsBackup` is needed to restore from a backup made with AWS Backup features.

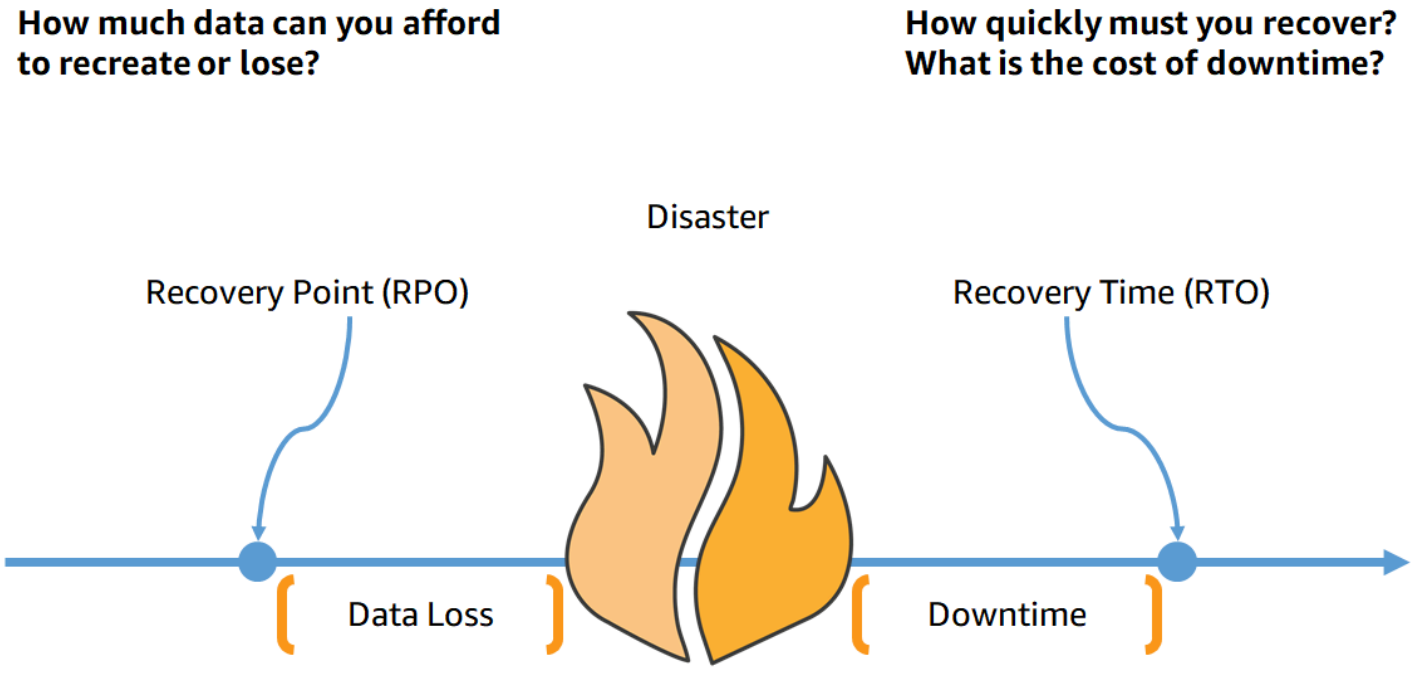
To see these permissions in a complete IAM policy, see Example 8 in Using IAM.

Choosing your disaster recovery strategy for Amazon DynamoDB workloads

Before selecting a DynamoDB DR strategy, you must define your business recovery requirements. This initial analysis prevents costly over-engineering while helping to make sure you meet critical business continuity needs. The optimal approach balances four key factors: recovery speed, data loss tolerance, implementation complexity, and operational costs.

Let's understand two key metrics that shape your DR strategy:

- **Recovery time objective (RTO)** – This is the maximum acceptable delay between the interruption of service and its restoration. RTO answers the question, How long can we afford to be down? This can range from zero (requiring continuous availability) to several hours, depending on business requirements.
- **Recovery point objective (RPO)** – This represents the maximum acceptable amount of time since the last data recovery point. RPO answers the question, How much data can we afford to lose? For example, if your RPO is 1 hour, your DR solution must make sure you can recover data to a point no more than 1 hour before an incident began.



Your choice of DynamoDB DR strategy should be based on the following factors:

- Business impact analysis of service disruption
- Risk assessment of different disaster scenarios
- Cost of implementing each DR option
- Regulatory requirements for data protection and availability

Decision points for selecting a DynamoDB DR approach

When selecting the appropriate DynamoDB DR approach, you must evaluate your specific business requirements, risk tolerance, regulatory requirements, and budget constraints.

For zero downtime requirements where revenue loss during outages significantly exceeds the additional operational costs, global tables, including multi-Region strong consistency (MRSC) tables, architectures provide instant recovery capabilities. While these solutions carry higher operational costs, they deliver immediate failover and continuous availability, making them essential for mission-critical applications where downtime directly impacts revenue streams.

Budget-conscious organizations with flexible recovery requirements can use more cost-effective solutions when applications can tolerate hours of downtime during recovery scenarios. On-demand backup, AWS Backup, or Amazon Simple Storage Service export strategies offer significantly lower operational costs while accepting longer recovery timeframes. These approaches work well for applications where business continuity is important but immediate recovery isn't financially justified, providing the option to balance protection with cost optimization.

Regulatory compliance requirements need automated solutions that ensure audit readiness and proper data retention policies. AWS Backup with cross-Region replication provides comprehensive compliance automation while maintaining higher cost structures. This approach delivers the documentation, retention policies, and geographic distribution required by regulatory frameworks while reducing manual compliance overhead and helping to ensure consistent backup procedures across the organization.

Protection against human-error scenarios such as accidental deletions or data corruption, point-in-time recovery (PITR) combined with deletion protection offers continuous protection within a single Region. While this solution provides excellent protection against operational mistakes and maintains reasonable costs, you must accept the single-Region limitation and plan additional strategies for true DR scenarios involving regional outages or infrastructure failures.

Disaster recovery options

DynamoDB offers options for backing up and restoring your table data, providing resilience against various failure scenarios. There are four main DR solutions that serve different needs:

- Point-in-time recovery (PITR) for continuous data protection
- On-demand backup and restore for flexible protection
- Scheduled backup and restore for automated regular protection
- Global tables for instant recovery of mission-critical workloads

Backup type	Backup option	Feature	RPO	RTO	Backup availability	Monthly backup cost	One-time restoration cost
Continuous data protection	PITR	Continuous backups retained for up to 35 days, enabling PITR within seconds of any moment in the configured backup window	Seconc	Minute	Single AWS Region only	$0.20 per GB-month	$0.15 per GB
On-demand protection	On-demand backup and restore	On-demand process	Hours	Minute	Single AWS Region	$0.10 per GB-month	$0.15 per GB

Backup type	Backup option	Feature	RPO	RTO	Backup availability	Monthly backup cost	One-time restoration cost
Scheduled backup and restore	AWS Backup	Flexible scheduling options (hourly to monthly)	Hours	Minute	Cross-Region backup is supported	$0.10 per GB-month	$0.15 per GB
	Amazon S3 export and import (with PITR enabled)	Export full or incremental data within PITR windows to an bucket	Minute	Hours	Cross-Region backup to bucket possible	$0.10 per GB	$0.15 per GB
Instant recovery for mission-critical workloads	Global tables	Fully managed solution, multi-Region, multi-active tables	Seconc	Zero	Automated propagation of data changes from primary to secondary Region within milliseconds	$0.625 per million replicated write request units	0

Backup type	Backup option	Feature	RPO	RTO	Backup availability	Monthly backup cost	One-time restoration cost
	MRSC tables	Fully managed solution, multi-Region, multi-active tables with strong consistency	Zero	Zero	Automated propagation of data changes from primary to secondary Region in real time	$0.625 per million replicated write request units	0

Note

Costs shown in the above table are based on N. Virginia Region prices from DynamoDB pricing for on-demand capacity.

Continuous data protection using PITR

Imagine an ecommerce retailer that uses DynamoDB for inventory management, product catalogs, and order processing. While preparing for a Black Friday event, the development team accidentally deletes their product catalog. Using PITR, they can restore thousands of records to the exact pre-incident moment in 30 minutes, preventing millions in potential revenue loss.

When you enable PITR, DynamoDB automatically backs up your table data with per-second granularity. You can restore your table to any given second within your configured recovery period, which ranges from 1–35 days. Notably, reducing the retention period does not decrease costs, making extended retention periods cost-neutral. The PITR feature provides granular recovery capabilities with minimal RPO (seconds) and reasonable RTO (minutes to hours), making it suitable for various DR requirements. Real-world scenarios demonstrate how PITR's minimal RPO and reasonable RTO transform potential business disasters into manageable recovery operations,

whether protecting against human error, application failures, or meeting stringent regulatory requirements.

To learn more, see Enable point-in-time recovery in DynamoDB, which provides detailed instructions on how to configure PITR and restore tables using CloudFormation, AWS CLI, and the DynamoDB API.

Flexible protection using on-demand backup and restore

Consider a healthcare provider planning a major electronic health record (EHR) system migration. Using milestone backups throughout the migration process would enable them to meet strict HIPAA requirements while providing their legal teams with immutable audit evidence. If compliance issues arose during migration, they could demonstrate exact data handling procedures and restore to any compliant checkpoint, ensuring patient data protection and regulatory adherence.

With the DynamoDB on-demand backup feature, you can create backups and restore tables as needed. On-demand backups operate asynchronously, capturing all changes up to the moment the backup request is made. On-demand backup capabilities give you precise control over your data protection strategy while supporting various operational and compliance requirements.

On-demand backup and restore offers flexible table restoration capabilities across both same-Region and cross-Region scenarios, providing you with versatile recovery options. For enhanced business continuity, DynamoDB delivers instantaneous backup completion regardless of table size, while same-region restorations provide optimal performance to minimize recovery time and maximize operational availability.

By implementing a daily backup strategy, you can achieve reliable RPO of 24 hours, complemented by predictable RTOs of minutes to hours. By using this structured approach to data protection, you can plan and execute your backup and recovery strategies effectively while maintaining business operations.

To learn more about DynamoDB backup and restore operations, see Backing up a DynamoDB table and Restoring a DynamoDB table from a backup.

Automated regular protection using scheduled backup and restore

DynamoDB provides multiple protection mechanisms that can be automated through scheduled workflows, including AWS Backup with customizable backup plans for operational recovery and Amazon S3 export capabilities for long-term archival, cross-Region data migration and continuous

operations. By implementing these automated regular protection schedules, you can ensure consistent data protection without manual intervention while balancing recovery objectives with storage costs.

Backup and restore using AWS Backup and backup plans

Consider a multinational bank with operations spanning 15 countries that needed to add enterprise-grade protection to their Amazon DynamoDB based fraud detection system; protection that could adapt to diverse regulatory requirements across jurisdictions while ensuring continuous availability.

Using the multi-Region replication and cross-account capabilities of AWS Backup, the bank implemented a protection architecture that automatically replicated critical transaction data across Regions while maintaining strict access controls for different business units. When regulators in three countries simultaneously requested historical transaction data for compliance audits, the bank's standardized backup policies and detailed audit trails enabled them to provide complete documentation within hours instead of weeks.

With AWS Backup you can take regular backups of your data within a specific AWS account. With backup plans, you can copy these backups to different Regions either on demand or automatically as part of a scheduled backup plan. Backup plans offer flexible scheduling options, so you can choose a frequency that suits your needs: every hour, every 12 hours, daily, weekly, or monthly. DynamoDB backups will be copied across Regions based on the selected frequency.

AWS Backup Vault Lock enforces write-once, read-many (WORM) backups to help protect backups (recovery points) in your backup vaults from inadvertent or malicious actions and provides protection against ransomware attacks. You can achieve a RPO of 1 hour and an RTO ranging from a few minutes to hours, depending on the table size.

To understand how AWS Backup integrates with DynamoDB and learn about backup features, and best practices, see Using AWS Backup with DynamoDB.

Amazon Simple Storage Service (Amazon S3) export and import

Imagine a global financial services firm that needs to meet regulatory requirements for transaction data across multiple jurisdictions while maintaining 99.99% availability. They could build their enterprise data strategy around the export and import capabilities of Amazon S3, implementing cross-Region data replication to comply with data sovereignty laws in 12 countries and establishing Regional failover mechanisms. Should a European outage occur, these systems would automatically execute failover procedures, helping to ensure zero trading disruption and continuous operations.

The company used the export/import to Amazon S3 feature to create daily full backups and hourly incremental exports to jurisdiction-specific Amazon S3 buckets across all 12 Regions, helping to ensure compliance with local data residency requirements. Each Regional table automatically exported transaction data to encrypted buckets within the same jurisdiction, while cross-Region replication provided additional redundancy for critical datasets. Exports don't consume read capacity units (RCUs) and have no impact on table performance or availability. If there's an impairment on one of the Regions where the company operates, automated recovery procedures can restore the most recent export to an alternate Region, enabling full trading operations to resume. This export/import strategy provides both regulatory compliance through immutable audit trails and robust DR capabilities. The firm can maintain continuous operations while preserving complete transaction histories that can be restored to new tables in any available Region, helping to minimize data loss and downtime during regional infrastructure failures.

With DynamoDB export to Amazon S3, you can export data from a DynamoDB table at a point within your PITR window. You can achieve an RPO of a few minutes and an RTO ranging from a few minutes to hours, depending on the table size.

For detailed implementation guidance on configuring exports, see Requesting a table export in DynamoDB. For restore operations and importing data from , see Requesting a table import in DynamoDB.

Instant recovery of mission-critical workloads using global tables

DynamoDB global tables provide robust failover capabilities during primary Region disruption; applications can immediately redirect traffic to healthy Regions and continue operations. Global tables have two options: multi-Region eventual consistency (MREC) and multi-Region strong consistency (MRSC).

Multi-Region eventual consistency

Imagine a multinational ecommerce service serving millions of customers across North America, Europe, and Asia-Pacific that could face significant operational challenges without proper global infrastructure. The company might struggle with slow checkout times for international customers, complex compliance requirements across multiple jurisdictions, and frequent disruptions during regional outages. By implementing DynamoDB global tables, they could transform their operations: customers in Tokyo would experience the same lightning-fast checkout times as those in New York through ultra-low latency local data access. Should a severe weather event disrupt their primary Region, their application could seamlessly fail over to another Region without customers noticing. This approach maintains high availability, improves global read and write

latency, supports regulatory compliance across the Regions where they operate, and gives the company confidence to expand into new markets knowing their infrastructure can scale reliably worldwide while meeting local requirements.

DynamoDB global tables offer a fully managed, multi-Region, multi-active database solution designed to provide fast and localized read and write performance for massively scaled global applications. For DR purposes, you can specify the primary Region and the DR Region where you want the tables to be available. DynamoDB automatically propagates ongoing data changes from the primary Region to the DR replica. With MREC setup, you can achieve an RPO of a few seconds and an RTO of zero.

For guidance on creating and managing DynamoDB global tables, see Global tables - multi-Region replication for DynamoDB.

Multi-Region strong consistency

Imagine a leading digital banking platform processing millions of transactions daily across three continents that could experience a significant regional outage during peak trading hours. Instead of scrambling with manual DR procedures and facing potential millions in losses, their architecture would activate DR within seconds, seamlessly redirecting traffic to healthy Regions without customers noticing a disruption. The bank's mobile app could continue processing loan applications in real-time, their trading platform would maintain millisecond response times for high-frequency transactions, and customer account balances would remain perfectly synchronized across all Regions.

With multi-Region strongly consistent global tables, you can build applications with zero RPO. An RPO of zero means your applications can read the most up-to-date version of DynamoDB data, even if an application interruption requires you to shift traffic to a different Region.

> **Note**
>
> For DR purposes, you can use two replicas and one witness Region.

For more information about creating MRSC global tables, see How global tables work.

Code examples for DynamoDB using AWS SDKs

The following code examples show how to use DynamoDB with an AWS software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Basic examples for DynamoDB using AWS SDKs

The following code examples show how to use the basics of Amazon DynamoDB with AWS SDKs.

Examples

- Hello DynamoDB
- Learn the basics of DynamoDB with an AWS SDK
- Actions for DynamoDB using AWS SDKs
  - Use BatchExecuteStatement with an AWS SDK
  - Use BatchGetItem with an AWS SDK or CLI
  - Use BatchWriteItem with an AWS SDK or CLI
  - Use CreateTable with an AWS SDK or CLI
  - Use DeleteItem with an AWS SDK or CLI

- Use DeleteTable with an AWS SDK or CLI
- Use DescribeTable with an AWS SDK or CLI
- Use DescribeTimeToLive with an AWS SDK or CLI
- Use ExecuteStatement with an AWS SDK
- Use GetItem with an AWS SDK or CLI
- Use ListTables with an AWS SDK or CLI
- Use PutItem with an AWS SDK or CLI
- Use Query with an AWS SDK or CLI
- Use Scan with an AWS SDK or CLI
- Use UpdateItem with an AWS SDK or CLI
- Use UpdateTable with an AWS SDK or CLI
- Use UpdateTimeToLive with an AWS SDK or CLI

Hello DynamoDB

The following code examples show how to get started using DynamoDB.

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Microsoft.Extensions.DependencyInjection;

namespace DynamoDBActions;

/// <summary>
/// A simple example that demonstrates basic DynamoDB operations.
```

```
/// </summary>
public class HelloDynamoDB
{
    /// <summary>
    /// HelloDynamoDB lists the existing DynamoDB tables for the default user.
    /// </summary>
    /// <param name="args">Command line arguments</param>
    /// <returns>Async task.</returns>
    static async Task Main(string[] args)
    {
        // Set up dependency injection for Amazon DynamoDB.
        using var host =
 Microsoft.Extensions.Hosting.Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonDynamoDB>()
            )
            .Build();

        // Now the client is available for injection.
        var dynamoDbClient = host.Services.GetRequiredService<IAmazonDynamoDB>();

        try
        {
            var request = new ListTablesRequest();
            var tableNames = new List<string>();

            var paginatorForTables =
 dynamoDbClient.Paginators.ListTables(request);

            await foreach (var tableName in paginatorForTables.TableNames)
            {
                tableNames.Add(tableName);
            }

            Console.WriteLine("Welcome to the DynamoDB Hello Service example. " +
                              "\nLet's list your DynamoDB tables:");
            tableNames.ForEach(table =>
            {
                Console.WriteLine($"Table: {table}");
            });
        }
        catch (AmazonDynamoDBException ex)
        {
```

```
            Console.WriteLine($"An Amazon DynamoDB service error occurred while
 listing tables. {ex.Message}");
        }
        catch (Exception ex)
        {
            Console.WriteLine($"An error occurred while listing tables.
 {ex.Message}");
        }
    }
}
```

- For API details, see ListTables in *AWS SDK for .NET API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Learn the basics of DynamoDB with an AWS SDK

The following code examples show how to:

- Create a table that can hold movie data.
- Put, get, and update a single movie in the table.
- Write movie data to the table from a sample JSON file.
- Query for movies that were released in a given year.
- Scan for movies that were released in a range of years.
- Delete a movie from the table, then delete the table.

Go

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario to create the table and perform actions on it.

```
import (
 "context"
 "fmt"
 "log"
 "strings"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/demotools"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/dynamodb/actions"
)

// RunMovieScenario is an interactive example that shows you how to use the AWS
 SDK for Go
// to create and use an Amazon DynamoDB table that stores data about movies.
//
//  1. Create a table that can hold movie data.
//  2. Put, get, and update a single movie in the table.
//  3. Write movie data to the table from a sample JSON file.
//  4. Query for movies that were released in a given year.
//  5. Scan for movies that were released in a range of years.
//  6. Delete a movie from the table.
//  7. Delete the table.
//
// This example creates a DynamoDB service client from the specified sdkConfig so
 that
// you can replace it with a mocked or stubbed config for unit testing.
//
// It uses a questioner from the `demotools` package to get input during the
 example.
// This package can be found in the ..\..\demotools folder of this repo.
//
// The specified movie sampler is used to get sample data from a URL that is
 loaded
// into the named table.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create a DynamoDB table.

```
// Create a table with a Sort key.
public static void createTable(DynamoDbClient ddb, String tableName) {
    DynamoDbWaiter dbWaiter = ddb.waiter();
    ArrayList<AttributeDefinition> attributeDefinitions = new ArrayList<>();

    // Define attributes.
    attributeDefinitions.add(AttributeDefinition.builder()
        .attributeName("year")
        .attributeType("N")
        .build());
```

```
        attributeDefinitions.add(AttributeDefinition.builder()
            .attributeName("title")
            .attributeType("S")
            .build());

        ArrayList<KeySchemaElement> tableKey = new ArrayList<>();
        KeySchemaElement key = KeySchemaElement.builder()
            .attributeName("year")
            .keyType(KeyType.HASH)
            .build();

        KeySchemaElement key2 = KeySchemaElement.builder()
            .attributeName("title")
            .keyType(KeyType.RANGE)
            .build();

        // Add KeySchemaElement objects to the list.
        tableKey.add(key);
        tableKey.add(key2);

        CreateTableRequest request = CreateTableRequest.builder()
            .keySchema(tableKey)
            .billingMode(BillingMode.PAY_PER_REQUEST) //  DynamoDB automatically
scales based on traffic.
            .attributeDefinitions(attributeDefinitions)
            .tableName(tableName)
            .build();

        try {
            CreateTableResponse response = ddb.createTable(request);
            DescribeTableRequest tableRequest = DescribeTableRequest.builder()
                .tableName(tableName)
                .build();

            // Wait until the Amazon DynamoDB table is created.
            WaiterResponse<DescribeTableResponse> waiterResponse =
dbWaiter.waitUntilTableExists(tableRequest);
            waiterResponse.matched().response().ifPresent(System.out::println);
            String newTable = response.tableDescription().tableName();
            System.out.println("The " + newTable + " was successfully created.");

        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
```

```
            System.exit(1);
        }
    }
```

Create a helper function to download and extract the sample JSON file.

```
    // Load data into the table.
    public static void loadData(DynamoDbClient ddb, String tableName, String
fileName) throws IOException {
        DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
            .dynamoDbClient(ddb)
            .build();

                }
            } else {
                System.out.format("No item found with the key %s!\n", "year");
            }

        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

Full example.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * <p>
 * For more information, see the following documentation topic:
 * <p>
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 * <p>
 * This Java example performs these tasks:
 * <p>
 * 1. Creates the Amazon DynamoDB Movie table with partition and sort key.
 * 2. Puts data into the Amazon DynamoDB table from a JSON document using the
 * Enhanced client.
 * 3. Gets data from the Movie table.
 * 4. Adds a new item.
 * 5. Updates an item.
 * 6. Uses a Scan to query items using the Enhanced client.
 * 7. Queries all items where the year is 2013 using the Enhanced Client.
 * 8. Deletes the table.
 */

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create a DynamoDB table.

```
suspend fun createScenarioTable(
    tableNameVal: String,
    key: String,
) {
    val attDef =
        AttributeDefinition {
            attributeName = key
            attributeType = ScalarAttributeType.N
        }

    val attDef1 =
        AttributeDefinition {
            attributeName = "title"
            attributeType = ScalarAttributeType.S
        }

    val keySchemaVal =
        KeySchemaElement {
            attributeName = key
            keyType = KeyType.Hash
```

```
        }

    val keySchemaVal1 =
        KeySchemaElement {
            attributeName = "title"
            keyType = KeyType.Range
        }

    val request =
        CreateTableRequest {
            attributeDefinitions = listOf(attDef, attDef1)
            keySchema = listOf(keySchemaVal, keySchemaVal1)
            billingMode = BillingMode.PayPerRequest
            tableName = tableNameVal
        }

    DynamoDbClient.fromEnvironment { region = "us-east-1" }.use { ddb ->
        val response = ddb.createTable(request)
        ddb.waitUntilTableExists {
            // suspend call
            tableName = tableNameVal
        }
        println("The table was successfully created
 ${response.tableDescription?.tableArn}")
    }
}
```

Create a helper function to download and extract the sample JSON file.

```
// Load data into the table.
suspend fun loadData(
    tableName: String,
    fileName: String,
) {
    val parser = JsonFactory().createParser(File(fileName))
    val rootNode = ObjectMapper().readTree<JsonNode>(parser)
    val iter: Iterator<JsonNode> = rootNode.iterator()
    var currentNode: ObjectNode

    var t = 0
    while (iter.hasNext()) {
        if (t == 50) {
```

```
            break
        }

        currentNode = iter.next() as ObjectNode
        val year = currentNode.path("year").asInt()
        val title = currentNode.path("title").asText()
        val info = currentNode.path("info").toString()
        putMovie(tableName, year, title, info)
        t++
    }
}

suspend fun putMovie(
    tableNameVal: String,
    year: Int,
    title: String,
    info: String,
) {
    val itemValues = mutableMapOf<String, AttributeValue>()
    val strVal = year.toString()
    // Add all content to the table.
    itemValues["year"] = AttributeValue.N(strVal)
    itemValues["title"] = AttributeValue.S(title)
    itemValues["info"] = AttributeValue.S(info)

    val request =
        PutItemRequest {
            tableName = tableNameVal
            item = itemValues
        }

    DynamoDbClient.fromEnvironment { region = "us-east-1" }.use { ddb ->
        ddb.putItem(request)
        println("Added $title to the Movie table.")
    }
}
```

Get an item from a table.

```
suspend fun getMovie(
    tableNameVal: String,
    keyName: String,
```

```
    keyVal: String,
) {
    val keyToGet = mutableMapOf<String, AttributeValue>()
    keyToGet[keyName] = AttributeValue.N(keyVal)
    keyToGet["title"] = AttributeValue.S("King Kong")

    val request =
        GetItemRequest {
            key = keyToGet
            tableName = tableNameVal
        }

    DynamoDbClient.fromEnvironment { region = "us-east-1" }.use { ddb ->
        val returnedItem = ddb.getItem(request)
        val numbersMap = returnedItem.item
        numbersMap?.forEach { key1 ->
            println(key1.key)
            println(key1.value)
        }
    }
}
```

Full example.

```
suspend fun main() {
    val tableName = "Movies"
    val fileName = "../../../resources/sample_files/movies.json"
    val partitionAlias = "#a"

    println("Creating an Amazon DynamoDB table named Movies with a key named id
 and a sort key named title.")
    createScenarioTable(tableName, "year")
    loadData(tableName, fileName)
    getMovie(tableName, "year", "1933")
    scanMovies(tableName)
    val count = queryMovieTable(tableName, "year", partitionAlias)
    println("There are $count Movies released in 2013.")
    deletIssuesTable(tableName)
}

Create a class that encapsulates a DynamoDB table.

```
# Creates an Amazon DynamoDB table that can be used to store movie data.
# The table uses the release year of the movie as the partition key and the
# title as the sort key.
#
# @param table_name [String] The name of the table to create.
# @return [Aws::DynamoDB::Table] The newly created table.
def create_table(table_name)
  @table = @dynamo_resource.create_table(
    table_name: table_name,
    key_schema: [
      { attribute_name: 'year', key_type: 'HASH' }, # Partition key
      { attribute_name: 'title', key_type: 'RANGE' } # Sort key
    ],
    attribute_definitions: [
      { attribute_name: 'year', attribute_type: 'N' },
      { attribute_name: 'title', attribute_type: 'S' }
    ],
    billing_mode: 'PAY_PER_REQUEST'
  )
  @dynamo_resource.client.wait_until(:table_exists, table_name: table_name)
  @table
rescue Aws::DynamoDB::Errors::ServiceError => e
  @logger.error("Failed create table #{table_name}:\n#{e.code}: #{e.message}")
  raise
end
```

Create a helper function to download and extract the sample JSON file.

```
  # Gets sample movie data, either from a local file or by first downloading it
 from
  # the Amazon DynamoDB Developer Guide.
  #
  # @param movie_file_name [String] The local file name where the movie data is
 stored in JSON format.
  # @return [Hash] The movie data as a Hash.
  def fetch_movie_data(movie_file_name)

Swift

SDK for Swift

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

A Swift class that handles DynamoDB calls to the SDK for Swift.

```
import AWSDynamoDB
import Foundation

/// An enumeration of error codes representing issues that can arise when using
/// the `MovieTable` class.
enum MoviesError: Error {
    /// The specified table wasn't found or couldn't be created.
    case TableNotFound
```

```
    /// The specified item wasn't found or couldn't be created.
    case ItemNotFound
    /// The Amazon DynamoDB client is not properly initialized.
    case UninitializedClient
    /// The table status reported by Amazon DynamoDB is not recognized.
    case StatusUnknown
    /// One or more specified attribute values are invalid or missing.
    case InvalidAttributes
}

/// A class representing an Amazon DynamoDB table containing movie
/// information.
public class MovieTable {
    var ddbClient: DynamoDBClient?
    let tableName: String

    /// Create an object representing a movie table in an Amazon DynamoDB
    /// database.
    ///
    /// - Parameters:
    ///   - region: The optional Amazon Region to create the database in.
    ///   - tableName: The name to assign to the table. If not specified, a
    ///     random table name is generated automatically.
    ///
    /// > Note: The table is not necessarily available when this function
    /// returns. Use `tableExists()` to check for its availability, or
    /// `awaitTableActive()` to wait until the table's status is reported as
    /// ready to use by Amazon DynamoDB.

Actions for DynamoDB using AWS SDKs

The following code examples demonstrate how to perform individual DynamoDB actions with AWS SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the DynamoDB API and are code excerpts from larger programs that must be run in context. You can see actions in context in Scenarios for DynamoDB using AWS SDKs.

The following examples include only the most commonly used actions. For a complete list, see the Amazon DynamoDB API Reference.

Examples

- Use BatchExecuteStatement with an AWS SDK
- Use BatchGetItem with an AWS SDK or CLI
- Use BatchWriteItem with an AWS SDK or CLI
- Use CreateTable with an AWS SDK or CLI
- Use DeleteItem with an AWS SDK or CLI
- Use DeleteTable with an AWS SDK or CLI
- Use DescribeTable with an AWS SDK or CLI
- Use DescribeTimeToLive with an AWS SDK or CLI
- Use ExecuteStatement with an AWS SDK
- Use GetItem with an AWS SDK or CLI
- Use ListTables with an AWS SDK or CLI

- Use PutItem with an AWS SDK or CLI
- Use Query with an AWS SDK or CLI
- Use Scan with an AWS SDK or CLI
- Use UpdateItem with an AWS SDK or CLI
- Use UpdateTable with an AWS SDK or CLI
- Use UpdateTimeToLive with an AWS SDK or CLI

Use `BatchExecuteStatement` with an AWS SDK

The following code examples show how to use `BatchExecuteStatement`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Delete data using PartiQL DELETE
- Insert data using PartiQL INSERT
- Query a table by using batches of PartiQL statements
- Query data using PartiQL SELECT
- Update data using PartiQL UPDATE

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Use batches of INSERT statements to add items.

```
        /// <summary>
        /// Inserts movies imported from a JSON file into the movie table by
        /// using an Amazon DynamoDB PartiQL INSERT statement.
        /// </summary>
        /// <param name="tableName">The name of the table into which the movie
```

```
        /// information will be inserted.</param>
        /// <param name="movieFileName">The name of the JSON file that contains
        /// movie information.</param>
        /// <returns>A Boolean value that indicates the success or failure of
        /// the insert operation.</returns>
        public static async Task<bool> InsertMovies(string tableName, string
movieFileName)
        {
            // Get the list of movies from the JSON file.
            var movies = ImportMovies(movieFileName);

```
attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(years[i]));
            statements[i].SetParameters(attributes);
        }

        Aws::DynamoDB::Model::BatchExecuteStatementRequest request;

        request.SetStatements(statements);
        Aws::DynamoDB::Model::BatchExecuteStatementOutcome outcome =
dynamoClient.BatchExecuteStatement(
                request);
        if (!outcome.IsSuccess()) {
            std::cerr << "Failed to update movie information: "
                      << outcome.GetError().GetMessage() << std::endl;
            return false;
        }
    }
```

Use batches of DELETE statements to delete items.

```
    // 6. Delete multiple movies using "Delete" statements.
(BatchExecuteStatement)
    {
        Aws::Vector<Aws::DynamoDB::Model::BatchStatementRequest> statements(
                titles.size());
        std::stringstream sqlStream;
        sqlStream << "DELETE FROM  \"" << MOVIE_TABLE_NAME << "\" WHERE "
                  << TITLE_KEY << "=? and " << YEAR_KEY << "=?";

        std::string sql(sqlStream.str());

        for (size_t i = 0; i < statements.size(); ++i) {
            statements[i].SetStatement(sql);
            Aws::Vector<Aws::DynamoDB::Model::AttributeValue> attributes;
            attributes.push_back(
                    Aws::DynamoDB::Model::AttributeValue().SetS(titles[i]));

attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(years[i]));
            statements[i].SetParameters(attributes);
        }

        Aws::DynamoDB::Model::BatchExecuteStatementRequest request;
```

```
        request.SetStatements(statements);

        Aws::DynamoDB::Model::BatchExecuteStatementOutcome outcome =
 dynamoClient.BatchExecuteStatement(
                request);

        if (!outcome.IsSuccess()) {
            std::cerr << "Failed to delete the movies: "
                      << outcome.GetError().GetMessage() << std::endl;
            return false;
        }
    }
```

Go

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Define a function receiver struct for the example.

```
import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// PartiQLRunner encapsulates the Amazon DynamoDB service actions used in the
```

```
// PartiQL examples. It contains a DynamoDB service client that is used to act on
 the
// specified table.
type PartiQLRunner struct {
 DynamoDbClient *dynamodb.Client
 TableName      string
}
```

Use batches of INSERT statements to add items.

```
// AddMovieBatch runs a batch of PartiQL INSERT statements to add multiple movies
 to the
// DynamoDB table.
func (runner PartiQLRunner) AddMovieBatch(ctx context.Context, movies []Movie)
 error {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{movie.Title,
 movie.Year, movie.Info})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(fmt.Sprintf(
    "INSERT INTO \"%v\" VALUE {'title': ?, 'year': ?, 'info': ?}",
 runner.TableName)),
   Parameters: params,
  }
 }

 _, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 if err != nil {
  log.Printf("Couldn't insert a batch of items with PartiQL. Here's why: %v\n",
 err)
 }
 return err
}
```

Use batches of SELECT statements to get items.

```
// GetMovieBatch runs a batch of PartiQL SELECT statements to get multiple movies
 from
// the DynamoDB table by title and year.
func (runner PartiQLRunner) GetMovieBatch(ctx context.Context, movies []Movie)
 ([]Movie, error) {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{movie.Title,
 movie.Year})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(
    fmt.Sprintf("SELECT * FROM \"%v\" WHERE title=? AND year=?",
 runner.TableName)),
   Parameters: params,
  }
 }

 output, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 var outMovies []Movie
 if err != nil {
  log.Printf("Couldn't get a batch of items with PartiQL. Here's why: %v\n", err)
 } else {
  for _, response := range output.Responses {
   var movie Movie
   err = attributevalue.UnmarshalMap(response.Item, &movie)
   if err != nil {
    log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
   } else {
    outMovies = append(outMovies, movie)
   }
  }
```

```
 }
 return outMovies, err
}
```

Use batches of UPDATE statements to update items.

```
// UpdateMovieBatch runs a batch of PartiQL UPDATE statements to update the
 rating of
// multiple movies that already exist in the DynamoDB table.
func (runner PartiQLRunner) UpdateMovieBatch(ctx context.Context, movies []Movie,
 ratings []float64) error {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{ratings[index],
 movie.Title, movie.Year})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(
    fmt.Sprintf("UPDATE \"%v\" SET info.rating=? WHERE title=? AND year=?",
 runner.TableName)),
   Parameters: params,
  }
 }

 _, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 if err != nil {
  log.Printf("Couldn't update the batch of movies. Here's why: %v\n", err)
 }
 return err
}
```

Use batches of DELETE statements to delete items.

```
// DeleteMovieBatch runs a batch of PartiQL DELETE statements to remove multiple
 movies
// from the DynamoDB table.
func (runner PartiQLRunner) DeleteMovieBatch(ctx context.Context, movies []Movie)
 error {
 statementRequests := make([]types.BatchStatementRequest, len(movies))
 for index, movie := range movies {
  params, err := attributevalue.MarshalList([]interface{}{movie.Title,
 movie.Year})
  if err != nil {
   panic(err)
  }
  statementRequests[index] = types.BatchStatementRequest{
   Statement: aws.String(
    fmt.Sprintf("DELETE FROM \"%v\" WHERE title=? AND year=?",
 runner.TableName)),
   Parameters: params,
  }
 }

 _, err := runner.DynamoDbClient.BatchExecuteStatement(ctx,
 &dynamodb.BatchExecuteStatementInput{
  Statements: statementRequests,
 })
 if err != nil {
  log.Printf("Couldn't delete the batch of movies. Here's why: %v\n", err)
 }
 return err
}
```

Define a Movie struct that is used in this example.

```
import (
 "archive/zip"
 "bytes"
 "encoding/json"
 "fmt"
 "io"
 "log"
```

```
 "net/http"

 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// Movie encapsulates data about a movie. Title and Year are the composite
 primary key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
 key,
// and Info is additional data.
type Movie struct {
 Title string                 `dynamodbav:"title"`
 Year  int                    `dynamodbav:"year"`
 Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
 title, err := attributevalue.Marshal(movie.Title)
 if err != nil {
  panic(err)
 }
 year, err := attributevalue.Marshal(movie.Year)
 if err != nil {
  panic(err)
 }
 return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
 example.
func (movie Movie) String() string {
 return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
  movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create a batch of items using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
  DynamoDBDocumentClient,
  BatchExecuteStatementCommand,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const breakfastFoods = ["Eggs", "Bacon", "Sausage"];
  const command = new BatchExecuteStatementCommand({
    Statements: breakfastFoods.map((food) => ({
      Statement: `INSERT INTO BreakfastFoods value {'Name':?}`,
      Parameters: [food],
    })),
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

Get a batch of items using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
```

```
  DynamoDBDocumentClient,
  BatchExecuteStatementCommand,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new BatchExecuteStatementCommand({
    Statements: [
      {
        Statement: "SELECT * FROM PepperMeasurements WHERE Unit=?",
        Parameters: ["Teaspoons"],
        ConsistentRead: true,
      },
      {
        Statement: "SELECT * FROM PepperMeasurements WHERE Unit=?",
        Parameters: ["Grams"],
        ConsistentRead: true,
      },
    ],
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

Update a batch of items using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
  DynamoDBDocumentClient,
  BatchExecuteStatementCommand,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const eggUpdates = [
```

```
    ["duck", "fried"],
    ["chicken", "omelette"],
  ];
  const command = new BatchExecuteStatementCommand({
    Statements: eggUpdates.map((change) => ({
      Statement: "UPDATE Eggs SET Style=? where Variety=?",
      Parameters: [change[1], change[0]],
    })),
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

Delete a batch of items using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
  DynamoDBDocumentClient,
  BatchExecuteStatementCommand,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new BatchExecuteStatementCommand({
    Statements: [
      {
        Statement: "DELETE FROM Flavors where Name=?",
        Parameters: ["Grape"],
      },
      {
        Statement: "DELETE FROM Flavors where Name=?",
        Parameters: ["Strawberry"],
      },
    ],
  });

  const response = await docClient.send(command);
```

```
  console.log(response);
  return response;
};
```

Ruby

SDK for Ruby

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Read a batch of items using PartiQL.

```
class DynamoDBPartiQLBatch
  attr_reader :dynamo_resource, :table

  def initialize(table_name)
    client = Aws::DynamoDB::Client.new(region: 'us-east-1')
    @dynamodb = Aws::DynamoDB::Resource.new(client: client)
    @table = @dynamodb.table(table_name)
  end

  # Selects a batch of items from a table using PartiQL
  #
  # @param batch_titles [Array] Collection of movie titles
  # @return [Aws::DynamoDB::Types::BatchExecuteStatementOutput]
  def batch_execute_select(batch_titles)
```

```
    request_items = batch_titles.map do |title, year|
      {
        statement: "SELECT * FROM \"#{@table.name}\" WHERE title=? and year=?",
        parameters: [title, year]
      }
    end
    @dynamodb.client.batch_execute_statement({ statements: request_items })
  end
```

Delete a batch of items using PartiQL.

```
class DynamoDBPartiQLBatch
  attr_reader :dynamo_resource, :table

  def initialize(table_name)
    client = Aws::DynamoDB::Client.new(region: 'us-east-1')
    @dynamodb = Aws::DynamoDB::Resource.new(client: client)
    @table = @dynamodb.table(table_name)
  end

  # Deletes a batch of items from a table using PartiQL
  #
  # @param batch_titles [Array] Collection of movie titles
  # @return [Aws::DynamoDB::Types::BatchExecuteStatementOutput]
  def batch_execute_write(batch_titles)
    request_items = batch_titles.map do |title, year|
      {
        statement: "DELETE FROM \"#{@table.name}\" WHERE title=? and year=?",
        parameters: [title, year]
      }
    end
    @dynamodb.client.batch_execute_statement({ statements: request_items })
  end
```

- For API details, see BatchExecuteStatement in *AWS SDK for Ruby API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `BatchGetItem` with an AWS SDK or CLI

The following code examples show how to use `BatchGetItem`.

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;

namespace LowLevelBatchGet
{
    public class LowLevelBatchGet
    {
        private static readonly string _table1Name = "Forum";
        private static readonly string _table2Name = "Thread";

        public static async void
 RetrieveMultipleItemsBatchGet(AmazonDynamoDBClient client)
        {
            var request = new BatchGetItemRequest
            {
                RequestItems = new Dictionary<string, KeysAndAttributes>()
            {
                { _table1Name,
                  new KeysAndAttributes
                  {
                      Keys = new List<Dictionary<string, AttributeValue> >()

}
```

- For API details, see BatchGetItem in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To retrieve multiple items from a table

The following `batch-get-items` example reads multiple items from the `MusicCollection` table using a batch of three `GetItem` requests, and requests the number of read capacity units consumed by the operation. The command returns only the `AlbumTitle` attribute.

```
aws dynamodb batch-get-item \
    --request-items file://request-items.json \
    --return-consumed-capacity TOTAL
```

Contents of `request-items.json`:

```
{
    "MusicCollection": {
        "Keys": [
            {
                "Artist": {"S": "No One You Know"},
                "SongTitle": {"S": "Call Me Today"}
            },
            {
                "Artist": {"S": "Acme Band"},
                "SongTitle": {"S": "Happy Day"}
            },
            {
                "Artist": {"S": "No One You Know"},
                "SongTitle": {"S": "Scared of My Shadow"}
            }
        ],
        "ProjectionExpression":"AlbumTitle"
    }
}
```

Output:

```
{
    "Responses": {
        "MusicCollection": [
            {
                "AlbumTitle": {
                    "S": "Somewhat Famous"
                }
            },
            {
                "AlbumTitle": {
                    "S": "Blue Sky Blues"
                }
            },
            {
                "AlbumTitle": {
                    "S": "Louder Than Ever"
                }
            }
        ]
    },
    "UnprocessedKeys": {},
    "ConsumedCapacity": [
        {
            "TableName": "MusicCollection",
            "CapacityUnits": 1.5
        }
    ]
}
```

This example uses the document client to simplify working with items in DynamoDB. For API details see BatchGet.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { BatchGetCommand, DynamoDBDocumentClient } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new BatchGetCommand({
    // Each key in this object is the name of a table. This example refers
    // to a Books table.
    RequestItems: {
      Books: {
        // Each entry in Keys is an object that specifies a primary key.
        Keys: [
          {
            Title: "How to AWS",
          },
          {
            Title: "DynamoDB for DBAs",
          },
        ],
        // Only return the "Title" and "PageCount" attributes.
        ProjectionExpression: "Title, PageCount",
      },
    },
  });

  const response = await docClient.send(command);
  console.log(response.Responses.Books);
  return response;
};
```

PowerShell

Tools for PowerShell V4

Example 1: Gets the item with the SongTitle "Somewhere Down The Road" from the DynamoDB tables 'Music' and 'Songs'.

```
$key = @{
    SongTitle = 'Somewhere Down The Road'
    Artist = 'No One You Know'
} | ConvertTo-DDBItem

$keysAndAttributes = New-Object Amazon.DynamoDBv2.Model.KeysAndAttributes
$list = New-Object
 'System.Collections.Generic.List[System.Collections.Generic.Dictionary[String,
 Amazon.DynamoDBv2.Model.AttributeValue]]'
$list.Add($key)
$keysAndAttributes.Keys = $list

$requestItem = @{
    'Music' = [Amazon.DynamoDBv2.Model.KeysAndAttributes]$keysAndAttributes
    'Songs' = [Amazon.DynamoDBv2.Model.KeysAndAttributes]$keysAndAttributes
}

$batchItems = Get-DDBBatchItem -RequestItem $requestItem
$batchItems.GetEnumerator() | ForEach-Object {$PSItem.Value} | ConvertFrom-
DDBItem
```

Output:

```

```
//! Batch write items from a JSON file.
/*!
  \sa batchWriteItem()
  \param jsonFilePath: JSON file path.
  \param clientConfiguration: AWS client configuration.
  \return bool: Function succeeded.
 */

/*
 * The input for this routine is a JSON file that you can download from the
 following URL:
 * https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/
SampleData.html.
```

```
 *
 * The JSON data uses the BatchWriteItem API request syntax. The JSON strings are
 * converted to AttributeValue objects. These AttributeValue objects will then
 generate
 * JSON strings when constructing the BatchWriteItem request, essentially
 outputting
 * their input.
 *
 * This is perhaps an artificial example, but it demonstrates the APIs.
 */

CLI

AWS CLI

To add multiple items to a table

The following `batch-write-item` example adds three new items to the `MusicCollection` table using a batch of three `PutItem` requests. It also requests information about the number of write capacity units consumed by the operation and any item collections modified by the operation.

```
aws dynamodb batch-write-item \
    --request-items file://request-items.json \
    --return-consumed-capacity INDEXES \
    --return-item-collection-metrics SIZE
```

Contents of `request-items.json`:

```
{
    "MusicCollection": [
        {
            "PutRequest": {
                "Item": {
                    "Artist": {"S": "No One You Know"},
                    "SongTitle": {"S": "Call Me Today"},
                    "AlbumTitle": {"S": "Somewhat Famous"}
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Artist": {"S": "Acme Band"},
                    "SongTitle": {"S": "Happy Day"},
                    "AlbumTitle": {"S": "Songs About Life"}
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Artist": {"S": "No One You Know"},
                    "SongTitle": {"S": "Scared of My Shadow"},
                    "AlbumTitle": {"S": "Blue Sky Blues"}
                }
            }
        }
    ]
}
```

Output:

```
{
```

```
    "UnprocessedItems": {},
    "ItemCollectionMetrics": {
        "MusicCollection": [
            {
                "ItemCollectionKey": {
                    "Artist": {
                        "S": "No One You Know"
                    }
                },
                "SizeEstimateRangeGB": [
                    0.0,
                    1.0
                ]
            },
            {
                "ItemCollectionKey": {
                    "Artist": {
                        "S": "Acme Band"
                    }

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example uses the document client to simplify working with items in DynamoDB. For API details see BatchWrite.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import {
  BatchWriteCommand,
  DynamoDBDocumentClient,
} from "@aws-sdk/lib-dynamodb";
import { readFileSync } from "node:fs";

// These modules are local to our GitHub repository. We recommend cloning
// the project from GitHub if you want to run this example.
// For more information, see https://github.com/awsdocs/aws-doc-sdk-examples.
import { dirnameFromMetaUrl } from "@aws-doc-sdk-examples/lib/utils/util-fs.js";
import { chunkArray } from "@aws-doc-sdk-examples/lib/utils/util-array.js";

const dirname = dirnameFromMetaUrl(import.meta.url);

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const file = readFileSync(
    `${dirname}../../../../../resources/sample_files/movies.json`,
  );

  const movies = JSON.parse(file.toString());

  // chunkArray is a local convenience function. It takes an array and returns
  // a generator function. The generator function yields every N items.
  const movieChunks = chunkArray(movies, 25);

  // For every chunk of 25 movies, make one BatchWrite request.
  for (const chunk of movieChunks) {
    const putRequests = chunk.map((movie) => ({
      PutRequest: {
        Item: movie,
      },
    }));

    const command = new BatchWriteCommand({
      RequestItems: {
        // An existing table is required. A composite key of 'title' and 'year'
 is recommended
        // to account for duplicate titles.
        BatchWriteMoviesTable: putRequests,
```

```
      },
    });

    await docClient.send(command);
  }
};
```

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `CreateTable` with an AWS SDK or CLI

The following code examples show how to use `CreateTable`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Accelerate reads with DAX
- Advanced Global Secondary Index scenarios
- Create a table with global secondary index
- Create a table with warm throughput enabled
- Create and manage global tables demonstrating MREC
- Create and manage MRSC global tables
- Getting started with NoSQL databases
- Manage Global Secondary Indexes
- Manage resource-based policies
- Set up Attribute-Based Access Control
- Work with global tables and multi-Region replication eventual consistency (MREC)
- Work with Local Secondary Indexes
- Work with resource tagging
- Work with Streams and Time-to-Live
- Work with table encryption

CLI

AWS CLI

Example 1: To create a table with tags

The following `create-table` example uses the specified attributes and key schema to create a table named `MusicCollection`. This table uses provisioned throughput and is encrypted at rest using the default AWS owned CMK. The command also applies a tag to the table, with a key of `Owner` and a value of `blueTeam`.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-
definitions AttributeName=Artist,AttributeType=S AttributeName=SongTitle,AttributeType=S
 \
    --key-
schema AttributeName=Artist,KeyType=HASH AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --tags Key=Owner,Value=blueTeam
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "WriteCapacityUnits": 5,
            "ReadCapacityUnits": 5
        },
        "TableSizeBytes": 0,
        "TableName": "MusicCollection",
        "TableStatus": "CREATING",
```

```
        "KeySchema": [
            {
                "KeyType": "HASH",
                "AttributeName": "Artist"
            },
            {
                "KeyType": "RANGE",
                "AttributeName": "SongTitle"
            }
        ],
        "ItemCount": 0,
        "CreationDateTime": "2020-05-26T16:04:41.627000-07:00",
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
MusicCollection",
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    }
}
```

For more information, see Basic Operations for Tables in the *Amazon DynamoDB Developer Guide*.

Example 2: To create a table in On-Demand Mode

The following example creates a table called `MusicCollection` using on-demand mode, rather than provisioned throughput mode. This is useful for tables with unpredictable workloads.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-
definitions AttributeName=Artist,AttributeType=S AttributeName=SongTitle,AttributeType=S
 \
    --key-
schema AttributeName=Artist,KeyType=HASH AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
```

```
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",
        "KeySchema": [
            {
                "AttributeName": "Artist",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "SongTitle",
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2020-05-27T11:44:10.807000-07:00",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "ReadCapacityUnits": 0,
            "WriteCapacityUnits": 0
        },
        "TableSizeBytes": 0,
        "ItemCount": 0,
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
MusicCollection",
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "BillingModeSummary": {
            "BillingMode": "PAY_PER_REQUEST"
        }
    }
}
```

For more information, see Basic Operations for Tables in the *Amazon DynamoDB Developer Guide*.

Example 3: To create a table and encrypt it with a Customer Managed CMK

The following example creates a table named `MusicCollection` and encrypts it using a customer managed CMK.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-
definitions AttributeName=Artist,AttributeType=S AttributeName=SongTitle,AttributeType=S
 \
    --key-
schema AttributeName=Artist,KeyType=HASH AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-
abcd-1234-a123-ab1234a1b234
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",
        "KeySchema": [
            {
                "AttributeName": "Artist",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "SongTitle",
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2020-05-27T11:12:16.431000-07:00",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "ReadCapacityUnits": 5,
            "WriteCapacityUnits": 5
        },

        }
    }
}
```

For more information, see Basic Operations for Tables in the *Amazon DynamoDB Developer Guide*.

Example 4: To create a table with a Local Secondary Index

The following example uses the specified attributes and key schema to create a table named `MusicCollection` with a Local Secondary Index named `AlbumTitleIndex`.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-
definitions AttributeName=Artist,AttributeType=S AttributeName=SongTitle,AttributeType=S
 \
    --key-
schema AttributeName=Artist,KeyType=HASH AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --local-secondary-indexes \
        "[
            {
                \"IndexName\": \"AlbumTitleIndex\",
                \"KeySchema\": [
                    {\"AttributeName\": \"Artist\",\"KeyType\":\"HASH\"},
                    {\"AttributeName\": \"AlbumTitle\",\"KeyType\":\"RANGE\"}
                ],
                \"Projection\": {
                    \"ProjectionType\": \"INCLUDE\",
                    \"NonKeyAttributes\": [\"Genre\", \"Year\"]
                }
            }
```

```
        ]"
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "AlbumTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",
        "KeySchema": [

                "IndexArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
MusicCollection/index/AlbumTitleIndex"
            }
        ]
    }
}
```

For more information, see Basic Operations for Tables in the *Amazon DynamoDB Developer Guide*.

Example 5: To create a table with a Global Secondary Index

The following example creates a table named `GameScores` with a Global Secondary Index called `GameTitleIndex`. The base table has a partition key of `UserId` and a sort key of `GameTitle`, allowing you to find an individual user's best score for a specific game efficiently, whereas the GSI has a partition key of `GameTitle` and a sort key of `TopScore`, allowing you to quickly find the overall highest score for a particular game.

```
aws dynamodb create-table \
    --table-name GameScores \
```

```
    --attribute-
definitions AttributeName=UserId,AttributeType=S AttributeName=GameTitle,AttributeType=S
 \
    --key-schema AttributeName=UserId,KeyType=HASH \
                 AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --global-secondary-indexes \
        "[
            {
                \"IndexName\": \"GameTitleIndex\",
                \"KeySchema\": [
                    {\"AttributeName\":\"GameTitle\",\"KeyType\":\"HASH\"},
                    {\"AttributeName\":\"TopScore\",\"KeyType\":\"RANGE\"}
                ],
                \"Projection\": {
                    \"ProjectionType\":\"INCLUDE\",
                    \"NonKeyAttributes\":[\"UserId\"]
                },
                \"ProvisionedThroughput\": {
                    \"ReadCapacityUnits\": 10,
                    \"WriteCapacityUnits\": 5
                }
            }
        ]"
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "TopScore",
                "AttributeType": "N"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
```

```
        "TableName": "GameScores",
        "KeySchema": [

                    "WriteCapacityUnits": 5
                },
                "IndexSizeBytes": 0,
                "ItemCount": 0,
                "IndexArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/index/GameTitleIndex"
            }
        ]
    }
}
```

For more information, see Basic Operations for Tables in the *Amazon DynamoDB Developer Guide*.

Example 6: To create a table with multiple Global Secondary Indexes at once

The following example creates a table named `GameScores` with two Global Secondary Indexes. The GSI schemas are passed via a file, rather than on the command line.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-
definitions AttributeName=UserId,AttributeType=S AttributeName=GameTitle,AttributeType=S
 \
    --key-
schema AttributeName=UserId,KeyType=HASH AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --global-secondary-indexes file://gsi.json
```

Contents of `gsi.json`:

```
[
    {
        "IndexName": "GameTitleIndex",
        "KeySchema": [
            {
                "AttributeName": "GameTitle",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "TopScore",
```

```
                "KeyType": "RANGE"
            }
        ],
        "Projection": {
            "ProjectionType": "ALL"
        },
        "ProvisionedThroughput": {
            "ReadCapacityUnits": 10,
            "WriteCapacityUnits": 5
        }
    },
    {
        "IndexName": "GameDateIndex",
        "KeySchema": [
            {
                "AttributeName": "GameTitle",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "Date",
                "KeyType": "RANGE"
            }
        ],
        "Projection": {
            "ProjectionType": "ALL"
        },
        "ProvisionedThroughput": {
            "ReadCapacityUnits": 5,
            "WriteCapacityUnits": 5
        }
    }
]
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Date",
                "AttributeType": "S"
            },
            {
```

```
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "TopScore",
                "AttributeType": "N"
            },
            {
                "AttributeName": "UserId",

                },
                "IndexSizeBytes": 0,
                "ItemCount": 0,
                "IndexArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/index/GameDateIndex"
            }
        ]
```

```
    }
}
```

For more information, see Basic Operations for Tables in the *Amazon DynamoDB Developer Guide*.

Example 7: To create a table with Streams enabled

The following example creates a table called `GameScores` with DynamoDB Streams enabled. Both new and old images of each item will be written to the stream.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-
definitions AttributeName=UserId,AttributeType=S AttributeName=GameTitle,AttributeType=S
 \
    --key-
schema AttributeName=UserId,KeyType=HASH AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=TRUE,StreamViewType=NEW_AND_OLD_IMAGES
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
        "TableName": "GameScores",
        "KeySchema": [
            {
                "AttributeName": "UserId",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "GameTitle",
```

```
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2020-05-27T10:49:34.056000-07:00",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "ReadCapacityUnits": 10,
            "WriteCapacityUnits": 5
        },
        "TableSizeBytes": 0,
        "ItemCount": 0,
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "StreamSpecification": {
            "StreamEnabled": true,
            "StreamViewType": "NEW_AND_OLD_IMAGES"
        },
        "LatestStreamLabel": "2020-05-27T17:49:34.056",
        "LatestStreamArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/stream/2020-05-27T17:49:34.056"
    }
}
```

For more information, see Basic Operations for Tables in the *Amazon DynamoDB Developer Guide*.

Example 8: To create a table with Keys-Only Stream enabled

The following example creates a table called `GameScores` with DynamoDB Streams enabled. Only the key attributes of modified items are written to the stream.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-
definitions AttributeName=UserId,AttributeType=S AttributeName=GameTitle,AttributeType=S
 \
    --key-
schema AttributeName=UserId,KeyType=HASH AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=TRUE,StreamViewType=KEYS_ONLY
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
        "TableName": "GameScores",
        "KeySchema": [
            {
                "AttributeName": "UserId",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "GameTitle",
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2023-05-25T18:45:34.140000+00:00",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "ReadCapacityUnits": 10,
            "WriteCapacityUnits": 5
        },
        "TableSizeBytes": 0,
        "ItemCount": 0,
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "StreamSpecification": {
            "StreamEnabled": true,
            "StreamViewType": "KEYS_ONLY"
        },
        "LatestStreamLabel": "2023-05-25T18:45:34.140",
        "LatestStreamArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/stream/2023-05-25T18:45:34.140",
        "DeletionProtectionEnabled": false
    }
```

```
}
```

For more information, see Change data capture for DynamoDB Streams in the *Amazon DynamoDB Developer Guide*.

Example 9: To create a table with the Standard Infrequent Access class

The following example creates a table called `GameScores` and assigns the Standard-Infrequent Access (DynamoDB Standard-IA) table class. This table class is optimized for storage being the dominant cost.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-
definitions AttributeName=UserId,AttributeType=S AttributeName=GameTitle,AttributeType=S
 \
    --key-
schema AttributeName=UserId,KeyType=HASH AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --table-class STANDARD_INFREQUENT_ACCESS
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
        "TableName": "GameScores",
        "KeySchema": [
            {
                "AttributeName": "UserId",
                "KeyType": "HASH"
            },
            {
```

```
                "AttributeName": "GameTitle",
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2023-05-25T18:33:07.581000+00:00",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "ReadCapacityUnits": 10,
            "WriteCapacityUnits": 5
        },
        "TableSizeBytes": 0,
        "ItemCount": 0,
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "TableClassSummary": {
            "TableClass": "STANDARD_INFREQUENT_ACCESS"
        },
        "DeletionProtectionEnabled": false
    }
}
```

For more information, see Table classes in the *Amazon DynamoDB Developer Guide*.

Example 10: To Create a table with Delete Protection enabled

The following example creates a table called `GameScores` and enables deletion protection.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-
definitions AttributeName=UserId,AttributeType=S AttributeName=GameTitle,AttributeType=S
 \
    --key-
schema AttributeName=UserId,KeyType=HASH AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --deletion-protection-enabled
```

Output:

```
{
    "TableDescription": {
```

```
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
        "TableName": "GameScores",
        "KeySchema": [
            {
                "AttributeName": "UserId",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "GameTitle",
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2023-05-25T23:02:17.093000+00:00",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "ReadCapacityUnits": 10,
            "WriteCapacityUnits": 5
        },

Create a table.

```
        $tableName = "ddb_demo_table_$uuid";
        $service->createTable(
            $tableName,
            [
                new DynamoDBAttribute('year', 'N', 'HASH'),
                new DynamoDBAttribute('title', 'S', 'RANGE')
            ]
        );

    public function createTable(string $tableName, array $attributes)
    {
        $keySchema = [];
        $attributeDefinitions = [];
        foreach ($attributes as $attribute) {
            if (is_a($attribute, DynamoDBAttribute::class)) {
```

```
                $keySchema[] = ['AttributeName' => $attribute->AttributeName,
'KeyType' => $attribute->KeyType];
                $attributeDefinitions[] =
                    ['AttributeName' => $attribute->AttributeName,
'AttributeType' => $attribute->AttributeType];
            }
        }

        $this->dynamoDbClient->createTable([
            'TableName' => $tableName,
            'KeySchema' => $keySchema,
            'AttributeDefinitions' => $attributeDefinitions,
            'ProvisionedThroughput' => ['ReadCapacityUnits' => 10,
'WriteCapacityUnits' => 10],
        ]);
    }
```

- For API details, see CreateTable in *AWS SDK for PHP API Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example creates a table named Thread that has a primary key consisting of 'ForumName' (key type hash) and 'Subject' (key type range). The schema used to construct the table can be piped into each cmdlet as shown or specified using the -Schema parameter.

```
$schema = New-DDBTableSchema
$schema | Add-DDBKeySchema -KeyName "ForumName" -KeyDataType "S"
$schema | Add-DDBKeySchema -KeyName "Subject" -KeyType RANGE -KeyDataType "S"
$schema | New-DDBTable -TableName "Thread" -ReadCapacity 10 -WriteCapacity 5
```

Output:

```
AttributeDefinitions   : {ForumName, Subject}
TableName              : Thread
KeySchema              : {ForumName, Subject}
TableStatus            : CREATING
CreationDateTime       : 10/28/2013 4:39:49 PM
ProvisionedThroughput  : Amazon.DynamoDBv2.Model.ProvisionedThroughputDescription
```

```
TableSizeBytes         : 0
ItemCount              : 0
LocalSecondaryIndexes  : {}
```

Example 2: This example creates a table named Thread that has a primary key consisting of 'ForumName' (key type hash) and 'Subject' (key type range). A local secondary index is also defined. The key of the local secondary index will be set automatically from the primary hash key on the table (ForumName). The schema used to construct the table can be piped into each cmdlet as shown or specified using the -Schema parameter.

```
$schema = New-DDBTableSchema
$schema | Add-DDBKeySchema -KeyName "ForumName" -KeyDataType "S"
$schema | Add-DDBKeySchema -KeyName "Subject" -KeyDataType "S"
$schema | Add-DDBIndexSchema -IndexName "LastPostIndex" -RangeKeyName
 "LastPostDateTime" -RangeKeyDataType "S" -ProjectionType "keys_only"
$schema | New-DDBTable -TableName "Thread" -ReadCapacity 10 -WriteCapacity 5
```

Output:

```
AttributeDefinitions   : {ForumName, LastPostDateTime, Subject}
TableName              : Thread
KeySchema              : {ForumName, Subject}
TableStatus            : CREATING
CreationDateTime       : 10/28/2013 4:39:49 PM
ProvisionedThroughput  : Amazon.DynamoDBv2.Model.ProvisionedThroughputDescription
TableSizeBytes         : 0
ItemCount              : 0
LocalSecondaryIndexes  : {LastPostIndex}
```

Example 3: This example shows how to use a single pipeline to create a table named Thread that has a primary key consisting of 'ForumName' (key type hash) and 'Subject' (key type range) and a local secondary index. The Add-DDBKeySchema and Add-DDBIndexSchema create a new TableSchema object for you if one is not supplied from the pipeline or the -Schema parameter.

```
New-DDBTableSchema |
  Add-DDBKeySchema -KeyName "ForumName" -KeyDataType "S" |
  Add-DDBKeySchema -KeyName "Subject" -KeyDataType "S" |
  Add-DDBIndexSchema -IndexName "LastPostIndex" `
                     -RangeKeyName "LastPostDateTime" `
```

```
                    -RangeKeyDataType "S" `
                    -ProjectionType "keys_only" |
  New-DDBTable -TableName "Thread" -ReadCapacity 10 -WriteCapacity 5
```

Output:

```
AttributeDefinitions   : {ForumName, LastPostDateTime, Subject}
TableName              : Thread
KeySchema              : {ForumName, Subject}
TableStatus            : CREATING
CreationDateTime       : 10/28/2013 4:39:49 PM
ProvisionedThroughput  : Amazon.DynamoDBv2.Model.ProvisionedThroughputDescription
TableSizeBytes         : 0
ItemCount              : 0
LocalSecondaryIndexes  : {LastPostIndex}
```

- For API details, see CreateTable in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example creates a table named Thread that has a primary key consisting of 'ForumName' (key type hash) and 'Subject' (key type range). The schema used to construct the table can be piped into each cmdlet as shown or specified using the -Schema parameter.

```
$schema = New-DDBTableSchema
$schema | Add-DDBKeySchema -KeyName "ForumName" -KeyDataType "S"
$schema | Add-DDBKeySchema -KeyName "Subject" -KeyType RANGE -KeyDataType "S"
$schema | New-DDBTable -TableName "Thread" -ReadCapacity 10 -WriteCapacity 5
```

Output:

```
AttributeDefinitions   : {ForumName, Subject}
TableName              : Thread
KeySchema              : {ForumName, Subject}
TableStatus            : CREATING
CreationDateTime       : 10/28/2013 4:39:49 PM

CLI

AWS CLI

Example 1: To delete an item

The following `delete-item` example deletes an item from the `MusicCollection` table and requests details about the item that was deleted and the capacity used by the request.

```
aws dynamodb delete-item \
    --table-name MusicCollection \
    --key file://key.json \
    --return-values ALL_OLD \
    --return-consumed-capacity TOTAL \
    --return-item-collection-metrics SIZE
```

Contents of `key.json`:

```
{
    "Artist": {"S": "No One You Know"},
    "SongTitle": {"S": "Scared of My Shadow"}
}
```

Output:

```
{
    "Attributes": {
        "AlbumTitle": {
            "S": "Blue Sky Blues"
        },
        "Artist": {
            "S": "No One You Know"
        },
        "SongTitle": {
            "S": "Scared of My Shadow"
        }
    },
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 2.0
    },
    "ItemCollectionMetrics": {
        "ItemCollectionKey": {
            "Artist": {
                "S": "No One You Know"
            }
        },
        "SizeEstimateRangeGB": [
```

```
            0.0,
            1.0
        ]
    }
}
```

For more information, see Writing an Item in the *Amazon DynamoDB Developer Guide*.

Example 2: To delete an item conditionally

The following example deletes an item from the `ProductCatalog` table only if its `ProductCategory` is either `Sporting Goods` or `Gardening Supplies` and its price is between 500 and 600. It returns details about the item that was deleted.

```
aws dynamodb delete-item \
    --table-name ProductCatalog \
    --key '{"Id":{"N":"456"}}' \
    --condition-expression "(ProductCategory IN (:cat1, :cat2)) and (#P
 between :lo and :hi)" \
    --expression-attribute-names file://names.json \
    --expression-attribute-values file://values.json \
    --return-values ALL_OLD
```

Contents of `names.json`:

```
{
    "#P": "Price"
}
```

Contents of `values.json`:

```
{
    ":cat1": {"S": "Sporting Goods"},
    ":cat2": {"S": "Gardening Supplies"},
    ":lo": {"N": "500"},
    ":hi": {"N": "600"}
}
```

Output:

```
{
    "Attributes": {
```

```
        "Id": {
            "N": "456"
        },
        "Price": {
            "N": "550"
        },
        "ProductCategory": {
            "S": "Sporting Goods"
        }
    }
}
```

For more information, see Writing an Item in the *Amazon DynamoDB Developer Guide*.

- For API details, see DeleteItem in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example uses the document client to simplify working with items in DynamoDB. For API details see DeleteCommand.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { DynamoDBDocumentClient, DeleteCommand } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new DeleteCommand({
    TableName: "Sodas",
    Key: {
      Flavor: "Cola",
    },
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DeleteItem in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Delete an item from a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
```

```
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });

var params = {
  TableName: "TABLE",
  Key: {
    KEY_NAME: { N: "VALUE" },
  },
};

// Call DynamoDB to delete the item from the table
ddb.deleteItem(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

Delete an item from a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  Key: {
    HASH_KEY: VALUE,
  },
  TableName: "TABLE",
};

docClient.delete(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DeleteTable` with an AWS SDK or CLI

The following code examples show how to use `DeleteTable`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Accelerate reads with DAX

- Create and manage MRSC global tables
- Getting started with NoSQL databases
- Manage Global Secondary Indexes
- Work with global tables and multi-Region replication eventual consistency (MREC)

CLI

AWS CLI

To delete a table

The following `delete-table` example deletes the `MusicCollection` table.

```
aws dynamodb delete-table \
    --table-name MusicCollection
```

Output:

```
{
    "TableDescription": {
        "TableStatus": "DELETING",
        "TableSizeBytes": 0,
        "ItemCount": 0,
        "TableName": "MusicCollection",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "WriteCapacityUnits": 5,
            "ReadCapacityUnits": 5
        }
    }
}
```

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DescribeTable` with an AWS SDK or CLI

The following code examples show how to use `DescribeTable`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Create and manage global tables demonstrating MREC
- Create and manage MRSC global tables
- Getting started with NoSQL databases
- Work with global tables and multi-Region replication eventual consistency (MREC)
- Work with Streams and Time-to-Live
- Work with table encryption

.NET

SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    private static async Task GetTableInformation()
    {
        Console.WriteLine("\n*** Retrieving table information ***");

        var response = await Client.DescribeTableAsync(new DescribeTableRequest
        {
            TableName = ExampleTableName
        });

        var table = response.Table;
        Console.WriteLine($"Name: {table.TableName}");
        Console.WriteLine($"# of items: {table.ItemCount}");

    }
```

- For API details, see DescribeTable in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To describe a table

The following `describe-table` example describes the `MusicCollection` table.

```
aws dynamodb describe-table \
    --table-name MusicCollection
```

Output:

```
{
```

```
    "Table": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "WriteCapacityUnits": 5,
            "ReadCapacityUnits": 5
        },
        "TableSizeBytes": 0,
        "TableName": "MusicCollection",
        "TableStatus": "ACTIVE",
        "KeySchema": [
            {
                "KeyType": "HASH",
                "AttributeName": "Artist"
            },
            {
                "KeyType": "RANGE",
                "AttributeName": "SongTitle"
            }
        ],
        "ItemCount": 0,
        "CreationDateTime": 1421866952.062
    }
}
```

Use `DescribeTimeToLive` with an AWS SDK or CLI

The following code examples show how to use `DescribeTimeToLive`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Work with Streams and Time-to-Live

CLI

AWS CLI

To view Time to Live settings for a table

The following `describe-time-to-live` example displays Time to Live settings for the `MusicCollection` table.

```
aws dynamodb describe-time-to-live \
    --table-name MusicCollection
```

Output:

```
{
    "TimeToLiveDescription": {
        "TimeToLiveStatus": "ENABLED",
        "AttributeName": "ttl"
    }
}
```

For more information, see Time to Live in the *Amazon DynamoDB Developer Guide*.

- For API details, see DescribeTimeToLive in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

Describe TTL configuration on an existing DynamoDB table using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DescribeTimeToLiveRequest;
import software.amazon.awssdk.services.dynamodb.model.DescribeTimeToLiveResponse;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;

import java.util.logging.Level;
import java.util.logging.Logger;

    public DescribeTimeToLiveResponse describeTTL(final String tableName, final
 Region region) {
        final DescribeTimeToLiveRequest request =
            DescribeTimeToLiveRequest.builder().tableName(tableName).build();

        try (DynamoDbClient ddb = dynamoDbClient != null
            ? dynamoDbClient
            : DynamoDbClient.builder().region(region).build()) {
            return ddb.describeTimeToLive(request);
        } catch (ResourceNotFoundException e) {
            System.err.format(TABLE_NOT_FOUND_ERROR, tableName);
            throw e;
        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            throw e;
        }
    }
```

- For API details, see DescribeTimeToLive in *AWS SDK for Java 2.x API Reference*.

JavaScript

SDK for JavaScript (v3)

Describe TTL configuration on an existing DynamoDB table using AWS SDK for JavaScript.

```
import { DynamoDBClient, DescribeTimeToLiveCommand } from "@aws-sdk/client-
dynamodb";

export const describeTTL = async (tableName, region) => {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    try {
        const ttlDescription = await client.send(new
 DescribeTimeToLiveCommand({ TableName: tableName }));

        if (ttlDescription.TimeToLiveDescription.TimeToLiveStatus === 'ENABLED')
 {
            console.log("TTL is enabled for table %s.", tableName);
        } else {
            console.log("TTL is not enabled for table %s.", tableName);
        }

        return ttlDescription;
    } catch (e) {
        console.error(`Error describing table: ${e}`);
        throw e;
    }
}

// Example usage (commented out for testing)
// describeTTL('your-table-name', 'us-east-1');
```

- For API details, see DescribeTimeToLive in *AWS SDK for JavaScript API Reference*.

Python

SDK for Python (Boto3)

Describe TTL configuration on an existing DynamoDB table using AWS SDK for Python (Boto3).

```
import boto3
```

```
def describe_ttl(table_name, region):
    """
    Describes TTL on an existing table, as well as a region.

    :param table_name: String representing the name of the table
    :param region: AWS Region of the table - example `us-east-1`
    :return: Time to live description.
    """
    try:
        dynamodb = boto3.resource("dynamodb", region_name=region)
        ttl_description = dynamodb.describe_time_to_live(TableName=table_name)
        print(
            f"TimeToLive for table {table_name} is status
 {ttl_description['TimeToLiveDescription']['TimeToLiveStatus']}"
        )

        return ttl_description
    except Exception as e:
        print(f"Error describing table: {e}")
        raise

# Enter your own table name and AWS region
describe_ttl("your-table-name", "us-east-1")
```

- For API details, see DescribeTimeToLive in *AWS SDK for Python (Boto3) API Reference*.

                {
                    new AttributeValue { S = movieTitle },
                    new AttributeValue { N = year.ToString() },
                },
            });
```

```
            return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
        }
```

Use a SELECT statement to get an item.

```
        /// <summary>
        /// Uses a PartiQL SELECT statement to retrieve a single movie from the
        /// movie database.
        /// </summary>
        /// <param name="tableName">The name of the movie table.</param>
        /// <param name="movieTitle">The title of the movie to retrieve.</param>
        /// <returns>A list of movie data. If no movie matches the supplied
        /// title, the list is empty.</returns>
        public static async Task<List<Dictionary<string, AttributeValue>>>
GetSingleMovie(string tableName, string movieTitle)
        {
            string selectSingle = $"SELECT * FROM {tableName} WHERE title = ?";
            var parameters = new List<AttributeValue>
            {
                new AttributeValue { S = movieTitle },
            };

            var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
            {
                Statement = selectSingle,
                Parameters = parameters,
            });

            return response.Items;
        }
```

Use a SELECT statement to get a list of items.

```
        /// <summary>
        /// Retrieve multiple movies by year using a SELECT statement.
        /// </summary>
```

```
        /// <param name="tableName">The name of the movie table.</param>
        /// <param name="year">The year the movies were released.</param>
        /// <returns></returns>
        public static async Task<List<Dictionary<string, AttributeValue>>>
GetMovies(string tableName, int year)
        {
            string selectSingle = $"SELECT * FROM {tableName} WHERE year = ?";
            var parameters = new List<AttributeValue>
            {
                new AttributeValue { N = year.ToString() },
            };

            var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
            {
                Statement = selectSingle,
                Parameters = parameters,
            });

            return response.Items;
        }
```

Use an UPDATE statement to update an item.

```
        /// <summary>
        /// Updates a single movie in the table, adding information for the
        /// producer.
        /// </summary>
        /// <param name="tableName">the name of the table.</param>
        /// <param name="producer">The name of the producer.</param>
        /// <param name="movieTitle">The movie title.</param>
        /// <param name="year">The year the movie was released.</param>
        /// <returns>A Boolean value that indicates the success of the
        /// UPDATE operation.</returns>
        public static async Task<bool> UpdateSingleMovie(string tableName, string
producer, string movieTitle, int year)
        {
            string insertSingle = $"UPDATE {tableName} SET Producer=? WHERE title
= ? AND year = ?";
```

```
            var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
            {
                Statement = insertSingle,
                Parameters = new List<AttributeValue>
                {
                    new AttributeValue { S = producer },
                    new AttributeValue { S = movieTitle },
                    new AttributeValue { N = year.ToString() },
                },
            });

            return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
        }
```

Use a DELETE statement to delete a single movie.

```
        /// <summary>
        /// Deletes a single movie from the table.
        /// </summary>
        /// <param name="tableName">The name of the table.</param>
        /// <param name="movieTitle">The title of the movie to delete.</param>
        /// <param name="year">The year that the movie was released.</param>
        /// <returns>A Boolean value that indicates the success of the
        /// DELETE operation.</returns>
        public static async Task<bool> DeleteSingleMovie(string tableName, string
movieTitle, int year)
        {
            var deleteSingle = $"DELETE FROM {tableName} WHERE title = ? AND year
= ?";

            var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
            {
                Statement = deleteSingle,
                Parameters = new List<AttributeValue>
                {
                    new AttributeValue { S = movieTitle },
                    new AttributeValue { N = year.ToString() },
                },
```

```
            });

            return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
        }
```

Use an INSERT statement to add an item.

```
    Aws::DynamoDB::DynamoDBClient dynamoClient(clientConfiguration);

    // 2. Add a new movie using an "Insert" statement. (ExecuteStatement)
    Aws::String title;
    float rating;
    int year;
    Aws::String plot;
    {
        title = askQuestion(
                "Enter the title of a movie you want to add to the table: ");
        year = askQuestionForInt("What year was it released? ");
        rating = askQuestionForFloatRange("On a scale of 1 - 10, how do you rate
it? ",
                                          1, 10);
        plot = askQuestion("Summarize the plot for me: ");

        Aws::DynamoDB::Model::ExecuteStatementRequest request;
        std::stringstream sqlStream;
        sqlStream << "INSERT INTO \"" << MOVIE_TABLE_NAME << "\" VALUE {'"
                  << TITLE_KEY << "': ?, '" << YEAR_KEY << "': ?, '"
                  << INFO_KEY << "': ?}";
```

```
        request.SetStatement(sqlStream.str());

        // Create the parameter attributes.
        Aws::Vector<Aws::DynamoDB::Model::AttributeValue> attributes;
        attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetS(title));
        attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(year));

        Aws::DynamoDB::Model::AttributeValue infoMapAttribute;

        std::shared_ptr<Aws::DynamoDB::Model::AttributeValue> ratingAttribute =
Aws::MakeShared<Aws::DynamoDB::Model::AttributeValue>(
                ALLOCATION_TAG.c_str());
        ratingAttribute->SetN(rating);
        infoMapAttribute.AddMEntry(RATING_KEY, ratingAttribute);

        std::shared_ptr<Aws::DynamoDB::Model::AttributeValue> plotAttribute =
Aws::MakeShared<Aws::DynamoDB::Model::AttributeValue>(
                ALLOCATION_TAG.c_str());
        plotAttribute->SetS(plot);
        infoMapAttribute.AddMEntry(PLOT_KEY, plotAttribute);
        attributes.push_back(infoMapAttribute);
        request.SetParameters(attributes);

        Aws::DynamoDB::Model::ExecuteStatementOutcome outcome =
dynamoClient.ExecuteStatement(
                request);

        if (!outcome.IsSuccess()) {
            std::cerr << "Failed to add a movie: " <<
outcome.GetError().GetMessage()
                      << std::endl;
            return false;
        }
    }
```

Use a SELECT statement to get an item.

```
    //  3. Get the data for the movie using a "Select" statement.
(ExecuteStatement)
    {
        Aws::DynamoDB::Model::ExecuteStatementRequest request;
```

```
        std::stringstream sqlStream;

            std::cerr << "Failed to delete the movie: "
                      << outcome.GetError().GetMessage() << std::endl;
            return false;
        }
    }
```

- For API details, see ExecuteStatement in *AWS SDK for C++ API Reference*.

Go

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Define a function receiver struct for the example.

```
import (
 "context"
 "fmt"
 "log"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
```

```
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// PartiQLRunner encapsulates the Amazon DynamoDB service actions used in the
// PartiQL examples. It contains a DynamoDB service client that is used to act on
 the
// specified table.
type PartiQLRunner struct {
 DynamoDbClient *dynamodb.Client
 TableName      string
}
```

Use an INSERT statement to add an item.

```
// AddMovie runs a PartiQL INSERT statement to add a movie to the DynamoDB table.
func (runner PartiQLRunner) AddMovie(ctx context.Context, movie Movie) error {
 params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year,
 movie.Info})
 if err != nil {
  panic(err)
 }
 _, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("INSERT INTO \"%v\" VALUE {'title': ?, 'year': ?, 'info': ?}",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't insert an item with PartiQL. Here's why: %v\n", err)
 }
 return err
}
```

Use a SELECT statement to get an item.

```
// GetMovie runs a PartiQL SELECT statement to get a movie from the DynamoDB
 table by
// title and year.
func (runner PartiQLRunner) GetMovie(ctx context.Context, title string, year int)
 (Movie, error) {
 var movie Movie
 params, err := attributevalue.MarshalList([]interface{}{title, year})
 if err != nil {
  panic(err)
 }
 response, err := runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("SELECT * FROM \"%v\" WHERE title=? AND year=?",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't get info about %v. Here's why: %v\n", title, err)
 } else {
  err = attributevalue.UnmarshalMap(response.Items[0], &movie)
  if err != nil {
   log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
  }
 }
 return movie, err
}
```

Use a SELECT statement to get a list of items and project the results.

```
// GetAllMovies runs a PartiQL SELECT statement to get all movies from the
 DynamoDB table.
// pageSize is not typically required and is used to show how to paginate the
 results.
// The results are projected to return only the title and rating of each movie.
func (runner PartiQLRunner) GetAllMovies(ctx context.Context, pageSize int32)
 ([]map[string]interface{}, error) {
 var output []map[string]interface{}
 var response *dynamodb.ExecuteStatementOutput
 var err error
```

```
 var nextToken *string
 for moreData := true; moreData; {
  response, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
   Statement: aws.String(
    fmt.Sprintf("SELECT title, info.rating FROM \"%v\"", runner.TableName)),
   Limit:     aws.Int32(pageSize),
   NextToken: nextToken,
  })
  if err != nil {
   log.Printf("Couldn't get movies. Here's why: %v\n", err)
   moreData = false
  } else {
   var pageOutput []map[string]interface{}
   err = attributevalue.UnmarshalListOfMaps(response.Items, &pageOutput)
   if err != nil {
    log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
   } else {
    log.Printf("Got a page of length %v.\n", len(response.Items))
    output = append(output, pageOutput...)
   }
   nextToken = response.NextToken
   moreData = nextToken != nil
  }
 }
 return output, err
}
```

Use an UPDATE statement to update an item.

```
// UpdateMovie runs a PartiQL UPDATE statement to update the rating of a movie
 that
// already exists in the DynamoDB table.
func (runner PartiQLRunner) UpdateMovie(ctx context.Context, movie Movie, rating
 float64) error {
 params, err := attributevalue.MarshalList([]interface{}{rating, movie.Title,
 movie.Year})
 if err != nil {
  panic(err)
 }
```

```
 _, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("UPDATE \"%v\" SET info.rating=? WHERE title=? AND year=?",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't update movie %v. Here's why: %v\n", movie.Title, err)
 }
 return err
}
```

Use a DELETE statement to delete an item.

```
// DeleteMovie runs a PartiQL DELETE statement to remove a movie from the
 DynamoDB table.
func (runner PartiQLRunner) DeleteMovie(ctx context.Context, movie Movie) error {
 params, err := attributevalue.MarshalList([]interface{}{movie.Title,
 movie.Year})
 if err != nil {
  panic(err)
 }
 _, err = runner.DynamoDbClient.ExecuteStatement(ctx,
 &dynamodb.ExecuteStatementInput{
  Statement: aws.String(
   fmt.Sprintf("DELETE FROM \"%v\" WHERE title=? AND year=?",
    runner.TableName)),
  Parameters: params,
 })
 if err != nil {
  log.Printf("Couldn't delete %v from the table. Here's why: %v\n", movie.Title,
 err)
 }
 return err
}
```

Define a Movie struct that is used in this example.

```
import (
 "archive/zip"
 "bytes"
 "encoding/json"
 "fmt"
 "io"
 "log"
 "net/http"

 "github.com/aws/aws-sdk-go-v2/feature/dynamodb/attributevalue"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb/types"
)

// Movie encapsulates data about a movie. Title and Year are the composite
 primary key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
 key,
// and Info is additional data.
type Movie struct {
 Title string                `dynamodbav:"title"`
 Year  int                   `dynamodbav:"year"`
 Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
 title, err := attributevalue.Marshal(movie.Title)
 if err != nil {
  panic(err)
 }
 year, err := attributevalue.Marshal(movie.Year)
 if err != nil {
  panic(err)
 }
 return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
 example.
func (movie Movie) String() string {
 return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
```

```
  movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

- For API details, see ExecuteStatement in *AWS SDK for Go API Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**

> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create an item using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
  ExecuteStatementCommand,
  DynamoDBDocumentClient,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new ExecuteStatementCommand({
    Statement: `INSERT INTO Flowers value {'Name':?}`,
    Parameters: ["Rose"],
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

Get an item using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
  ExecuteStatementCommand,
  DynamoDBDocumentClient,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new ExecuteStatementCommand({
    Statement: "SELECT * FROM CloudTypes WHERE IsStorm=?",
    Parameters: [false],
    ConsistentRead: true,
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

Update an item using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
  ExecuteStatementCommand,
  DynamoDBDocumentClient,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new ExecuteStatementCommand({
    Statement: "UPDATE EyeColors SET IsRecessive=? where Color=?",
    Parameters: [true, "blue"],
  });
```

```
  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

Delete an item using PartiQL.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

import {
  ExecuteStatementCommand,
  DynamoDBDocumentClient,
} from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new ExecuteStatementCommand({
    Statement: "DELETE FROM PaintColors where Name=?",
    Parameters: ["Purple"],
  });

Select a single item using PartiQL.

```
class DynamoDBPartiQLSingle
  attr_reader :dynamo_resource, :table

  def initialize(table_name)
    client = Aws::DynamoDB::Client.new(region: 'us-east-1')
    @dynamodb = Aws::DynamoDB::Resource.new(client: client)
    @table = @dynamodb.table(table_name)
  end
```

```
  # Gets a single record from a table using PartiQL.
  # Note: To perform more fine-grained selects,
  # use the Client.query instance method instead.
  #
  # @param title [String] The title of the movie to search.
  # @return [Aws::DynamoDB::Types::ExecuteStatementOutput]
  def select_item_by_title(title)
    request = {
      statement: "SELECT * FROM \"#{@table.name}\" WHERE title=?",
      parameters: [title]
    }
    @dynamodb.client.execute_statement(request)
  end
```

Update a single item using PartiQL.

```
class DynamoDBPartiQLSingle
  attr_reader :dynamo_resource, :table

  def initialize(table_name)
    client = Aws::DynamoDB::Client.new(region: 'us-east-1')
    @dynamodb = Aws::DynamoDB::Resource.new(client: client)
    @table = @dynamodb.table(table_name)
  end

  # Updates a single record from a table using PartiQL.
  #
  # @param title [String] The title of the movie to update.
  # @param year [Integer] The year the movie was released.
  # @param rating [Float] The new rating to assign the title.
  # @return [Aws::DynamoDB::Types::ExecuteStatementOutput]
  def update_rating_by_title(title, year, rating)
    request = {
      statement: "UPDATE \"#{@table.name}\" SET info.rating=? WHERE title=? and
 year=?",
      parameters: [{ "N": rating }, title, year]
    }
    @dynamodb.client.execute_statement(request)
  end
```

Add a single item using PartiQL.

```
class DynamoDBPartiQLSingle
  attr_reader :dynamo_resource, :table

  def initialize(table_name)
    client = Aws::DynamoDB::Client.new(region: 'us-east-1')
    @dynamodb = Aws::DynamoDB::Resource.new(client: client)
    @table = @dynamodb.table(table_name)
  end

  # Adds a single record to a table using PartiQL.
  #
  # @param title [String] The title of the movie to update.
  # @param year [Integer] The year the movie was released.
  # @param plot [String] The plot of the movie.
  # @param rating [Float] The new rating to assign the title.
  # @return [Aws::DynamoDB::Types::ExecuteStatementOutput]
  def insert_item(title, year, plot, rating)
    request = {
      statement: "INSERT INTO \"#{@table.name}\" VALUE {'title': ?, 'year': ?,
 'info': ?}",
      parameters: [title, year, { 'plot': plot, 'rating': rating }]
    }
    @dynamodb.client.execute_statement(request)
  end
```

Delete a single item using PartiQL.

```
class DynamoDBPartiQLSingle
  attr_reader :dynamo_resource, :table

  def initialize(table_name)
    client = Aws::DynamoDB::Client.new(region: 'us-east-1')
    @dynamodb = Aws::DynamoDB::Resource.new(client: client)
    @table = @dynamodb.table(table_name)
  end

  # Deletes a single record from a table using PartiQL.
  #
  # @param title [String] The title of the movie to update.
  # @param year [Integer] The year the movie was released.
```

```
  # @return [Aws::DynamoDB::Types::ExecuteStatementOutput]
  def delete_item_by_title(title, year)
    request = {
      statement: "DELETE FROM \"#{@table.name}\" WHERE title=? and year=?",
      parameters: [title, year]
    }
    @dynamodb.client.execute_statement(request)
  end
```

```
###############################################################################
# function dynamodb_get_item
#
# This function gets an item from a DynamoDB table.
#
# Parameters:
#       -n table_name  -- The name of the table.
#       -k keys  -- Path to json file containing the keys that identify the item
 to get.
#       [-q query]  -- Optional JMESPath query expression.
#
#  Returns:
#       The item as text output.
#  And:
#       0 - If successful.
#       1 - If it fails.
###############################################################################
function dynamodb_get_item() {
  local table_name keys query response
  local option OPTARG # Required to use getopts command in a function.

    }

    return outcome.IsSuccess();
}
```

- For API details, see GetItem in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To read an item in a table

The following `get-item` example retrieves an item from the `MusicCollection` table. The table has a hash-and-range primary key (`Artist` and `SongTitle`), so you must specify both of these attributes. The command also requests information about the read capacity consumed by the operation.

```
aws dynamodb get-item \
    --table-name MusicCollection \
    --key file://key.json \
    --return-consumed-capacity TOTAL
```

Contents of `key.json`:

```
{
    "Artist": {"S": "Acme Band"},
    "SongTitle": {"S": "Happy Day"}
}
```

Output:

```
{
    "Item": {
        "AlbumTitle": {
            "S": "Songs About Life"
        },
        "SongTitle": {
            "S": "Happy Day"
        },
        "Artist": {
            "S": "Acme Band"
        }
    },
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 0.5
    }
}
```

For more information, see Reading an Item in the *Amazon DynamoDB Developer Guide*.

Example 2: To read an item using a consistent read

The following example retrieves an item from the `MusicCollection` table using strongly consistent reads.

```
aws dynamodb get-item \
    --table-name MusicCollection \
    --key file://key.json \
    --consistent-read \
    --return-consumed-capacity TOTAL
```

Contents of `key.json`:

```
{
    "Artist": {"S": "Acme Band"},
    "SongTitle": {"S": "Happy Day"}
}
```

Output:

```
{
    "Item": {
        "AlbumTitle": {
            "S": "Songs About Life"
        },
        "SongTitle": {
            "S": "Happy Day"
        },
        "Artist": {
            "S": "Acme Band"
        }
    },
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 1.0
    }
}
```

For more information, see Reading an Item in the *Amazon DynamoDB Developer Guide*.

Example 3: To retrieve specific attributes of an item

The following example uses a projection expression to retrieve only three attributes of the desired item.

```
aws dynamodb get-item \
    --table-name ProductCatalog \
    --key '{"Id": {"N": "102"}}' \
    --projection-expression "#T, #C, #P" \
    --expression-attribute-names file://names.json
```

Contents of `names.json`:

```
{
    "#T": "Title",
    "#C": "ProductCategory",
    "#P": "Price"
}
```

Output:

```
{
```

```
    "Item": {
        "Price": {
            "N": "20"
        },
        "Title": {
            "S": "Book 102 Title"
        },
        "ProductCategory": {
            "S": "Book"
        }
    }
}
```

For more information, see Reading an Item in the *Amazon DynamoDB Developer Guide*.

- For API details, see GetItem in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example uses the document client to simplify working with items in DynamoDB. For API details see GetCommand.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { DynamoDBDocumentClient, GetCommand } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new GetCommand({
    TableName: "AngryAnimals",
```

```
    Key: {
      CommonName: "Shoebill",
    },
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For API details, see GetItem in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Get an item from a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });

var params = {
  TableName: "TABLE",
  Key: {
    KEY_NAME: { N: "001" },
  },
  ProjectionExpression: "ATTRIBUTE_NAME",
};

// Call DynamoDB to read the item from the table
ddb.getItem(params, function (err, data) {
  if (err) {
    console.log("Error", err);
```

```
  } else {
    console.log("Success", data.Item);
  }
});
```

Get an item from a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  TableName: "EPISODES_TABLE",
  Key: { KEY_NAME: VALUE },
};

docClient.get(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data.Item);
  }
});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see GetItem in *AWS SDK for JavaScript API Reference*.

>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
//! List the Amazon DynamoDB tables for the current AWS account.
/*!
  \sa listTables()
  \param clientConfiguration: AWS client configuration.
  \return bool: Function succeeded.
 */

bool AwsDoc::DynamoDB::listTables(
        const Aws::Client::ClientConfiguration &clientConfiguration) {
    Aws::DynamoDB::DynamoDBClient dynamoClient(clientConfiguration);

    Aws::DynamoDB::Model::ListTablesRequest listTablesRequest;
    listTablesRequest.SetLimit(50);
    do {
        const Aws::DynamoDB::Model::ListTablesOutcome &outcome =
 dynamoClient.ListTables(
                listTablesRequest);
        if (!outcome.IsSuccess()) {
            std::cout << "Error: " << outcome.GetError().GetMessage() <<
 std::endl;
            return false;
```

```
        }

        for (const auto &tableName: outcome.GetResult().GetTableNames())
            std::cout << tableName << std::endl;
        listTablesRequest.SetExclusiveStartTableName(
                outcome.GetResult().GetLastEvaluatedTableName());

    } while (!listTablesRequest.GetExclusiveStartTableName().empty());

    return true;
}
```

- For API details, see ListTables in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To list tables

The following `list-tables` example lists all of the tables associated with the current AWS account and Region.

```
aws dynamodb list-tables
```

Output:

```
{
    "TableNames": [
        "Forum",
        "ProductCatalog",
        "Reply",
        "Thread"
    ]
}
```

For more information, see Listing Table Names in the *Amazon DynamoDB Developer Guide*.

Example 2: To limit page size

The following example returns a list of all existing tables, but retrieves only one item in each call, performing multiple calls if necessary to get the entire list. Limiting the page size is useful when running list commands on a large number of resources, which can result in a "timed out" error when using the default page size of 1000.

```
aws dynamodb list-tables \
    --page-size 1
```

Output:

```
{
    "TableNames": [
        "Forum",
        "ProductCatalog",
        "Reply",
        "Thread"
    ]
}
```

For more information, see Listing Table Names in the *Amazon DynamoDB Developer Guide*.

Example 3: To limit the number of items returned

The following example limits the number of items returned to 2. The response includes a `NextToken` value with which to retrieve the next page of results.

```
aws dynamodb list-tables \
    --max-items 2
```

Output:

```
{
    "TableNames": [
        "Forum",
        "ProductCatalog"
    ],
    "NextToken":
 "abCDeFGhiJKlmnOPqrSTuvwxYZ1aBCdEFghijK7LM51nOpqRSTuv3WxY3ZabC5dEFGhI2Jk3LmnoPQ6RST9"
}
```

For more information, see Listing Table Names in the *Amazon DynamoDB Developer Guide*.

Example 4: To retrieve the next page of results

The following command uses the `NextToken` value from a previous call to the `list-tables` command to retrieve another page of results. Since the response in this case does not include a `NextToken` value, we know that we have reached the end of the results.

```
aws dynamodb list-tables \
    --starting-
token abCDeFGhiJKlmnOPqrSTuvwxYZ1aBCdEFghijK7LM51nOpqRSTuv3WxY3ZabC5dEFGhI2Jk3LmnoPQ6RST9
```

Output:

```
{
    "TableNames": [
        "Reply",
        "Thread"
    ]
}
```

For more information, see Listing Table Names in the *Amazon DynamoDB Developer Guide*.

- For API details, see ListTables in *AWS CLI Command Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `PutItem` with an AWS SDK or CLI

The following code examples show how to use `PutItem`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Accelerate reads with DAX
- Advanced Global Secondary Index scenarios
- Create an item with a TTL
- Create and manage global tables demonstrating MREC
- Create and manage MRSC global tables
- Getting started with NoSQL databases
- Use conditional operations
- Work with global tables and multi-Region replication eventual consistency (MREC)
- Work with Streams and Time-to-Live

.NET

                      << result.GetError().GetMessage() << std::endl;
            return false;
        }
        count++;
    }
    return false;
}
```

- For API details, see PutItem in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To add an item to a table

The following `put-item` example adds a new item to the *MusicCollection* table.

```
aws dynamodb put-item \
    --table-name MusicCollection \
    --item file://item.json \
    --return-consumed-capacity TOTAL \
    --return-item-collection-metrics SIZE
```

Contents of `item.json`:

```
{
    "Artist": {"S": "No One You Know"},
    "SongTitle": {"S": "Call Me Today"},
    "AlbumTitle": {"S": "Greatest Hits"}
}
```

Output:

```
{
    "ConsumedCapacity": {
```

```
        "TableName": "MusicCollection",
        "CapacityUnits": 1.0
    },
    "ItemCollectionMetrics": {
        "ItemCollectionKey": {
            "Artist": {
                "S": "No One You Know"
            }
        },
        "SizeEstimateRangeGB": [
            0.0,
            1.0
        ]
    }
}
```

For more information, see Writing an Item in the *Amazon DynamoDB Developer Guide*.

Example 2: To conditionally overwrite an item in a table

The following `put-item` example overwrites an existing item in the `MusicCollection` table only if that existing item has an `AlbumTitle` attribute with a value of `Greatest Hits`. The command returns the previous value of the item.

```
aws dynamodb put-item \
    --table-name MusicCollection \
    --item file://item.json \
    --condition-expression "#A = :A" \
    --expression-attribute-names file://names.json \
    --expression-attribute-values file://values.json \
    --return-values ALL_OLD
```

Contents of `item.json`:

```
{
    "Artist": {"S": "No One You Know"},
    "SongTitle": {"S": "Call Me Today"},
    "AlbumTitle": {"S": "Somewhat Famous"}
}
```

Contents of `names.json`:

```
{
    "#A": "AlbumTitle"
}
```

Contents of `values.json`:

```
{
    ":A": {"S": "Greatest Hits"}
}
```

Output:

```
{
    "Attributes": {
        "AlbumTitle": {
            "S": "Greatest Hits"
        },
        "Artist": {
            "S": "No One You Know"
        },
        "SongTitle": {
            "S": "Call Me Today"
        }
    }
}
```

If the key already exists, you should see the following output:

```
A client error (ConditionalCheckFailedException) occurred when calling the
 PutItem operation: The conditional request failed.
```

For more information, see Writing an Item in the *Amazon DynamoDB Developer Guide*.

- For API details, see PutItem in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example uses the document client to simplify working with items in DynamoDB. For API details see PutCommand.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { PutCommand, DynamoDBDocumentClient } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);
```

```
export const main = async () => {
  const command = new PutCommand({
    TableName: "HappyAnimals",
    Item: {
      CommonName: "Shiba Inu",
    },
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For API details, see PutItem in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Put an item in a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });

var params = {
  TableName: "CUSTOMER_LIST",
  Item: {
    CUSTOMER_ID: { N: "001" },
    CUSTOMER_NAME: { S: "Richard Roe" },
  },
};

// Call DynamoDB to add the item to the table
```

```
ddb.putItem(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

Put an item in a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  TableName: "TABLE",
  Item: {
    HASHKEY: VALUE,
    ATTRIBUTE_1: "STRING_VALUE",
    ATTRIBUTE_2: VALUE_2,
  },
};

docClient.put(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see PutItem in *AWS SDK for JavaScript API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `Query` with an AWS SDK or CLI

The following code examples show how to use `Query`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Accelerate reads with DAX
- Advanced Global Secondary Index scenarios
- Compare multiple values with a single attribute
- Getting started with NoSQL databases
- Manage Global Secondary Indexes
- Perform advanced query operations
- Query a table using a begins_with condition
- Query a table using a date range
- Query a table using a Global Secondary Index
- Query a table with a complex filter expression
- Query a table with a dynamic filter expression
- Query a table with a filter expression and limit
- Query a table with nested attributes

- Query a table with pagination
- Query a table with strongly consistent reads
- Query for TTL items
- Query tables using date and time patterns
- Use expression attribute names
- Work with Local Secondary Indexes

CLI

AWS CLI

Example 1: To query a table

The following `query` example queries items in the `MusicCollection` table. The table has a hash-and-range primary key (`Artist` and `SongTitle`), but this query only specifies the hash key value. It returns song titles by the artist named "No One You Know".

```
aws dynamodb query \
    --table-name MusicCollection \
    --projection-expression "SongTitle" \
    --key-condition-expression "Artist = :v1" \
    --expression-attribute-values file://expression-attributes.json \
    --return-consumed-capacity TOTAL
```

Contents of `expression-attributes.json`:

```
{
    ":v1": {"S": "No One You Know"}
}
```

Output:

```
{
    "Items": [
        {
            "SongTitle": {
                "S": "Call Me Today"
            },
            "SongTitle": {
                "S": "Scared of My Shadow"
            }
        }
    ],
    "Count": 2,
    "ScannedCount": 2,
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 0.5
    }
}
```

For more information, see Working with Queries in DynamoDB in the *Amazon DynamoDB Developer Guide*.

Example 2: To query a table using strongly consistent reads and traverse the index in descending order

The following example performs the same query as the first example, but returns results in reverse order and uses strongly consistent reads.

```
aws dynamodb query \
    --table-name MusicCollection \
    --projection-expression "SongTitle" \
    --key-condition-expression "Artist = :v1" \
    --expression-attribute-values file://expression-attributes.json \
    --consistent-read \
    --no-scan-index-forward \
    --return-consumed-capacity TOTAL
```

Contents of `expression-attributes.json`:

```
{
    ":v1": {"S": "No One You Know"}
}
```

Output:

```
{
    "Items": [
        {
            "SongTitle": {
                "S": "Scared of My Shadow"
            }
        },
        {
            "SongTitle": {
                "S": "Call Me Today"
            }
        }
    ],
    "Count": 2,
    "ScannedCount": 2,
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 1.0
    }
}
```

For more information, see Working with Queries in DynamoDB in the *Amazon DynamoDB Developer Guide*.

Example 3: To filter out specific results

The following example queries the `MusicCollection` but excludes results with specific values in the `AlbumTitle` attribute. Note that this does not affect the `ScannedCount` or `ConsumedCapacity`, because the filter is applied after the items have been read.

```
aws dynamodb query \
    --table-name MusicCollection \
    --key-condition-expression "#n1 = :v1" \
    --filter-expression "NOT (#n2 IN (:v2, :v3))" \
    --expression-attribute-names file://names.json \
    --expression-attribute-values file://values.json \
    --return-consumed-capacity TOTAL
```

Contents of `values.json`:

```
{
    ":v1": {"S": "No One You Know"},
    ":v2": {"S": "Blue Sky Blues"},
    ":v3": {"S": "Greatest Hits"}
}
```

Contents of `names.json`:

```
{
    "#n1": "Artist",
    "#n2": "AlbumTitle"
}
```

Output:

```
{
    "Items": [
        {
            "AlbumTitle": {
                "S": "Somewhat Famous"
            },
            "Artist": {
                "S": "No One You Know"
            },
            "SongTitle": {
                "S": "Call Me Today"
            }
```

```
        }
    ],
    "Count": 1,
    "ScannedCount": 2,
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 0.5
    }
}
```

For more information, see Working with Queries in DynamoDB in the *Amazon DynamoDB Developer Guide*.

Example 4: To retrieve only an item count

The following example retrieves a count of items matching the query, but does not retrieve any of the items themselves.

```
aws dynamodb query \
    --table-name MusicCollection \
    --select COUNT \
    --key-condition-expression "Artist = :v1" \
    --expression-attribute-values file://expression-attributes.json
```

Contents of `expression-attributes.json`:

```
{
    ":v1": {"S": "No One You Know"}
}
```

Output:

```
{
    "Count": 2,
    "ScannedCount": 2,
    "ConsumedCapacity": null
}
```

For more information, see Working with Queries in DynamoDB in the *Amazon DynamoDB Developer Guide*.

Example 5: To query an index

The following example queries the local secondary index `AlbumTitleIndex`. The query returns all attributes from the base table that have been projected into the local secondary index. Note that when querying a local secondary index or global secondary index, you must also provide the name of the base table using the `table-name` parameter.

```
aws dynamodb query \
    --table-name MusicCollection \
    --index-name AlbumTitleIndex \
    --key-condition-expression "Artist = :v1" \
    --expression-attribute-values file://expression-attributes.json \
    --select ALL_PROJECTED_ATTRIBUTES \
    --return-consumed-capacity INDEXES
```

Contents of `expression-attributes.json`:

```
{
    ":v1": {"S": "No One You Know"}
}
```

Output:

```
{
    "Items": [
        {
            "AlbumTitle": {
                "S": "Blue Sky Blues"
            },
            "Artist": {
                "S": "No One You Know"
            },
            "SongTitle": {
                "S": "Scared of My Shadow"
            }
        },
        {
            "AlbumTitle": {
                "S": "Somewhat Famous"
            },
            "Artist": {
                "S": "No One You Know"
            },
            "SongTitle": {
```

```
                "S": "Call Me Today"
            }
        }
    ],
    "Count": 2,
    "ScannedCount": 2,
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 0.5,
        "Table": {
            "CapacityUnits": 0.0
        },
        "LocalSecondaryIndexes": {
            "AlbumTitleIndex": {
                "CapacityUnits": 0.5
            }
        }
    }
}
```

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example uses the document client to simplify working with items in DynamoDB. For API details see QueryCommand.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { QueryCommand, DynamoDBDocumentClient } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new QueryCommand({
    TableName: "CoffeeCrop",
    KeyConditionExpression:
      "OriginCountry = :originCountry AND RoastDate > :roastDate",
    ExpressionAttributeValues: {
      ":originCountry": "Ethiopia",
      ":roastDate": "2023-05-01",
    },
    ConsistentRead: true,
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see Query in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  ExpressionAttributeValues: {
    ":s": 2,
    ":e": 9,
    ":topic": "PHRASE",
  },
  KeyConditionExpression: "Season = :s and Episode > :e",
  FilterExpression: "contains (Subtitle, :topic)",
  TableName: "EPISODES_TABLE",
};

docClient.query(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data.Items);
  }
});
```

PowerShell

Tools for PowerShell V4

Example 1: Invokes a query that returns DynamoDB items with the specified SongTitle and Artist.

```
$invokeDDBQuery = @{
    TableName = 'Music'
    KeyConditionExpression = ' SongTitle = :SongTitle and Artist = :Artist'
    ExpressionAttributeValues = @{
        ':SongTitle' = 'Somewhere Down The Road'
        ':Artist' = 'No One You Know'
    } | ConvertTo-DDBItem
}
Invoke-DDBQuery @invokeDDBQuery | ConvertFrom-DDBItem
```

Output:

```
Name                           Value
----                           -----
Genre                          Country
Artist                         No One You Know
Price                          1.94
CriticRating                   9
SongTitle                      Somewhere Down The Road
AlbumTitle                     Somewhat Famous
```

- For API details, see Query in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Invokes a query that returns DynamoDB items with the specified SongTitle and Artist.

```
$invokeDDBQuery = @{
```

```
    TableName = 'Music'
    KeyConditionExpression = ' SongTitle = :SongTitle and Artist = :Artist'
    ExpressionAttributeValues = @{
        ':SongTitle' = 'Somewhere Down The Road'

CLI

AWS CLI

To scan a table

The following `scan` example scans the entire `MusicCollection` table, and then narrows the results to songs by the artist "No One You Know". For each item, only the album title and song title are returned.

```
aws dynamodb scan \
    --table-name MusicCollection \
    --filter-expression "Artist = :a" \
    --projection-expression "#ST, #AT" \
    --expression-attribute-names file://expression-attribute-names.json \
    --expression-attribute-values file://expression-attribute-values.json
```

Contents of `expression-attribute-names.json`:

```
{
    "#ST": "SongTitle",
    "#AT":"AlbumTitle"
}
```

Contents of `expression-attribute-values.json`:

```
{
    ":a": {"S": "No One You Know"}
}
```

Output:

```
{
    "Count": 2,
    "Items": [
        {
            "SongTitle": {
                "S": "Call Me Today"
            },
```

```
            "AlbumTitle": {
                "S": "Somewhat Famous"
            }
        },
        {
            "SongTitle": {
                "S": "Scared of My Shadow"
            },
            "AlbumTitle": {
                "S": "Blue Sky Blues"
            }
        }
    ],
    "ScannedCount": 3,
    "ConsumedCapacity": null
}
```

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example uses the document client to simplify working with items in DynamoDB. For API details see ScanCommand.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { DynamoDBDocumentClient, ScanCommand } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new ScanCommand({
    ProjectionExpression: "#Name, Color, AvgLifeSpan",
    ExpressionAttributeNames: { "#Name": "Name" },
    TableName: "Birds",
  });

  const response = await docClient.send(command);
  for (const bird of response.Items) {
    console.log(`${bird.Name} - (${bird.Color}, ${bird.AvgLifeSpan})`);
  }
  return response;
};
```

- For API details, see Scan in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
// Load the AWS SDK for Node.js.
var AWS = require("aws-sdk");
// Set the AWS Region.
AWS.config.update({ region: "REGION" });

// Create DynamoDB service object.
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });
```

```
const params = {
  // Specify which items in the results are returned.
  FilterExpression: "Subtitle = :topic AND Season = :s AND Episode = :e",
  // Define the expression attribute value, which are substitutes for the values
 you want to compare.
  ExpressionAttributeValues: {
    ":topic": { S: "SubTitle2" },
    ":s": { N: 1 },
    ":e": { N: 2 },
  },
  // Set the projection expression, which are the attributes that you want.
  ProjectionExpression: "Season, Episode, Title, Subtitle",
  TableName: "EPISODES_TABLE",
};

ddb.scan(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
    data.Items.forEach(function (element, index, array) {
      console.log(
        "printing",
        element.Title.S + " (" + element.Subtitle.S + ")"
      );
    });
  }
});
```

PowerShell

Tools for PowerShell V4

Example 1: Returns all items in the Music table.

```
Invoke-DDBScan -TableName 'Music' | ConvertFrom-DDBItem
```

Output:

```
Name                           Value
----                           -----
Genre                          Country
Artist                         No One You Know
Price                          1.94
CriticRating                   9
SongTitle                      Somewhere Down The Road
AlbumTitle                     Somewhat Famous
Genre                          Country
Artist                         No One You Know
Price                          1.98
CriticRating                   8.4
SongTitle                      My Dog Spot
AlbumTitle                     Hey Now
```

Example 2: Returns items in the Music table with a CriticRating greater than or equal to nine.

```
$scanFilter = @{
        CriticRating = [Amazon.DynamoDBv2.Model.Condition]@{
            AttributeValueList = @(@{N = '9'})
            ComparisonOperator = 'GE'
        }
    }
    Invoke-DDBScan -TableName 'Music' -ScanFilter $scanFilter | ConvertFrom-
DDBItem
```

Output:

```
Name                           Value
----                           -----
Genre                          Country
Artist                         No One You Know
Price                          1.94
CriticRating                   9
SongTitle                      Somewhere Down The Road
AlbumTitle                     Somewhat Famous
```

- For API details, see Scan in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Returns all items in the Music table.

```
Invoke-DDBScan -TableName 'Music' | ConvertFrom-DDBItem
```

Output:

```
Name                           Value
----                           -----

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `UpdateItem` with an AWS SDK or CLI

The following code examples show how to use `UpdateItem`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Conditionally update an item's TTL
- Count expression operators
- Create and manage MRSC global tables
- Getting started with NoSQL databases
- Perform list operations
- Perform map operations
- Perform set operations
- Understand update expression order
- Update an item's TTL
- Use atomic counter operations
- Use conditional operations
- Use expression attribute names

CLI

AWS CLI

Example 1: To update an item in a table

The following `update-item` example updates an item in the `MusicCollection` table. It adds a new attribute (`Year`) and modifies the `AlbumTitle` attribute. All of the attributes in the item, as they appear after the update, are returned in the response.

```
aws dynamodb update-item \
    --table-name MusicCollection \
```

```
    --key file://key.json \
    --update-expression "SET #Y = :y, #AT = :t" \
    --expression-attribute-names file://expression-attribute-names.json \
    --expression-attribute-values file://expression-attribute-values.json  \
    --return-values ALL_NEW \
    --return-consumed-capacity TOTAL \
    --return-item-collection-metrics SIZE
```

Contents of `key.json`:

```
{
    "Artist": {"S": "Acme Band"},
    "SongTitle": {"S": "Happy Day"}
}
```

Contents of `expression-attribute-names.json`:

```
{
    "#Y":"Year", "#AT":"AlbumTitle"
}
```

Contents of `expression-attribute-values.json`:

```
{
    ":y":{"N": "2015"},
    ":t":{"S": "Louder Than Ever"}
}
```

Output:

```
{
    "Attributes": {
        "AlbumTitle": {
            "S": "Louder Than Ever"
        },
        "Awards": {
            "N": "10"
        },
        "Artist": {
            "S": "Acme Band"
        },
        "Year": {
```

```
            "N": "2015"
        },
        "SongTitle": {
            "S": "Happy Day"
        }
    },
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 3.0
    },
    "ItemCollectionMetrics": {
        "ItemCollectionKey": {
            "Artist": {
                "S": "Acme Band"
            }
        },
        "SizeEstimateRangeGB": [
            0.0,
            1.0
        ]
    }
}
```

For more information, see Writing an Item in the *Amazon DynamoDB Developer Guide*.

Example 2: To update an item conditionally

The following example updates an item in the `MusicCollection` table, but only if the existing item does not already have a `Year` attribute.

```
aws dynamodb update-item \
    --table-name MusicCollection \
    --key file://key.json \
    --update-expression "SET #Y = :y, #AT = :t" \
    --expression-attribute-names file://expression-attribute-names.json \
    --expression-attribute-values file://expression-attribute-values.json  \
    --condition-expression "attribute_not_exists(#Y)"
```

Contents of `key.json`:

```
{
    "Artist": {"S": "Acme Band"},
    "SongTitle": {"S": "Happy Day"}
```

```
}
```

Contents of `expression-attribute-names.json`:

```
{
    "#Y":"Year",
    "#AT":"AlbumTitle"
}
```

Contents of `expression-attribute-values.json`:

```
{
    ":y":{"N": "2015"},
    ":t":{"S": "Louder Than Ever"}
}
```

If the item already has a `Year` attribute, DynamoDB returns the following output.

```
An error occurred (ConditionalCheckFailedException) when calling the UpdateItem
 operation: The conditional request failed
```

For more information, see Writing an Item in the *Amazon DynamoDB Developer Guide*.

- For API details, see UpdateItem in *AWS CLI Command Reference*.

Updates an item in a table using DynamoDbClient.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.AttributeAction;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.AttributeValueUpdate;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemRequest;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
```

```
import java.util.HashMap;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * To update an Amazon DynamoDB table using the AWS SDK for Java V2, its better
 * practice to use the
 * Enhanced Client, See the EnhancedModifyItem example.
 */
public class UpdateItem {
    public static void main(String[] args) {
        final String usage = """

                Usage:
                    <tableName> <key> <keyVal> <name> <updateVal>

                Where:
                    tableName - The Amazon DynamoDB table (for example, Music3).
                    key - The name of the key in the table (for example, Artist).
                    keyVal - The value of the key (for example, Famous Band).
                    name - The name of the column where the value is updated (for
 example, Awards).
                    updateVal - The value used to update an item (for example,
 14).
                 Example:
                    UpdateItem Music3 Artist Famous Band Awards 14
                """;

        if (args.length != 5) {

This example uses the document client to simplify working with items in DynamoDB. For API details see UpdateCommand.

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { DynamoDBDocumentClient, UpdateCommand } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new UpdateCommand({
    TableName: "Dogs",
    Key: {
      Breed: "Labrador",
    },
    UpdateExpression: "set Color = :color",
    ExpressionAttributeValues: {
      ":color": "black",
    },
    ReturnValues: "ALL_NEW",
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For API details, see UpdateItem in *AWS SDK for JavaScript API Reference*.

Kotlin

PowerShell

Tools for PowerShell V4

Example 1: Sets the genre attribute to 'Rap' on the DynamoDB item with the partition key SongTitle and the sort key Artist.

```
$key = @{
    SongTitle = 'Somewhere Down The Road'
    Artist = 'No One You Know'
} | ConvertTo-DDBItem

$updateDdbItem = @{
    TableName = 'Music'
    Key = $key
    UpdateExpression = 'set Genre = :val1'
    ExpressionAttributeValue = (@{
        ':val1' = ([Amazon.DynamoDBv2.Model.AttributeValue]'Rap')
    })
}
Update-DDBItem @updateDdbItem
```

Output:

```
Name                           Value
----                           -----
Genre                          Rap
```

- For API details, see UpdateItem in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Sets the genre attribute to 'Rap' on the DynamoDB item with the partition key SongTitle and the sort key Artist.

```
$key = @{
    SongTitle = 'Somewhere Down The Road'
    Artist = 'No One You Know'
} | ConvertTo-DDBItem
```

```
$updateDdbItem = @{
    TableName = 'Music'
    Key = $key
    UpdateExpression = 'set Genre = :val1'
    ExpressionAttributeValue = (@{
        ':val1' = ([Amazon.DynamoDBv2.Model.AttributeValue]'Rap')
    })
}
Update-DDBItem @updateDdbItem
```

Output:

```
Name                           Value
----                           -----
Genre                          Rap
```

- For API details, see UpdateItem in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `UpdateTable` with an AWS SDK or CLI

The following code examples show how to use `UpdateTable`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Create and manage global tables demonstrating MREC
- Create and manage MRSC global tables
- Manage Global Secondary Indexes
- Update a table's warm throughput setting
- Work with global tables and multi-Region replication eventual consistency (MREC)
- Work with table encryption

C++

```
//! Update a DynamoDB table.
/*!
  \sa updateTable()
  \param tableName: Name for the DynamoDB table.
  \param readCapacity: Provisioned read capacity.
  \param writeCapacity: Provisioned write capacity.
  \param clientConfiguration: AWS client configuration.
  \return bool: Function succeeded.
 */
bool AwsDoc::DynamoDB::updateTable(const Aws::String &tableName,
```

```
                                    long long readCapacity, long long
writeCapacity,
                                    const Aws::Client::ClientConfiguration
&clientConfiguration) {
   Aws::DynamoDB::DynamoDBClient dynamoClient(clientConfiguration);

   std::cout << "Updating " << tableName << " with new provisioned throughput
values"
             << std::endl;
   std::cout << "Read capacity : " << readCapacity << std::endl;
   std::cout << "Write capacity: " << writeCapacity << std::endl;

   Aws::DynamoDB::Model::UpdateTableRequest request;
   Aws::DynamoDB::Model::ProvisionedThroughput provisionedThroughput;

provisionedThroughput.WithReadCapacityUnits(readCapacity).WithWriteCapacityUnits(
           writeCapacity);

request.WithProvisionedThroughput(provisionedThroughput).WithTableName(tableName);

   const Aws::DynamoDB::Model::UpdateTableOutcome &outcome =
dynamoClient.UpdateTable(
           request);
   if (outcome.IsSuccess()) {
       std::cout << "Successfully updated the table." << std::endl;
   } else {
       const Aws::DynamoDB::DynamoDBError &error = outcome.GetError();
       if (error.GetErrorType() == Aws::DynamoDB::DynamoDBErrors::VALIDATION &&
           error.GetMessage().find("The provisioned throughput for the table
will not change") != std::string::npos) {
           std::cout << "The provisioned throughput for the table will not
change." << std::endl;
       } else {
           std::cerr << outcome.GetError().GetMessage() << std::endl;
           return false;
       }
   }

   return waitTableActive(tableName, dynamoClient);
}
```

Code that waits for the table to become active.

```
//! Query a newly created DynamoDB table until it is active.
/*!
  \sa waitTableActive()
  \param waitTableActive: The DynamoDB table's name.
  \param dynamoClient: A DynamoDB client.
  \return bool: Function succeeded.
*/
bool AwsDoc::DynamoDB::waitTableActive(const Aws::String &tableName,
                                       const Aws::DynamoDB::DynamoDBClient
 &dynamoClient) {

    // Repeatedly call DescribeTable until table is ACTIVE.
    const int MAX_QUERIES = 20;

        if (result.IsSuccess()) {
            Aws::DynamoDB::Model::TableStatus status =
 result.GetResult().GetTable().GetTableStatus();

            if (Aws::DynamoDB::Model::TableStatus::ACTIVE != status) {
                std::this_thread::sleep_for(std::chrono::seconds(1));
            }
            else {
                return true;
            }
        }
        else {
            std::cerr << "Error DynamoDB::waitTableActive "
                      << result.GetError().GetMessage() << std::endl;
            return false;
        }
        count++;
    }
    return false;
}
```

- For API details, see UpdateTable in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To modify a table's billing mode

The following `update-table` example increases the provisioned read and write capacity on the `MusicCollection` table.

```
aws dynamodb update-table \
    --table-name MusicCollection \
    --billing-mode PROVISIONED \
    --provisioned-throughput ReadCapacityUnits=15,WriteCapacityUnits=10
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "AlbumTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",
        "KeySchema": [
            {
                "AttributeName": "Artist",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "SongTitle",
```

```
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "UPDATING",
        "CreationDateTime": "2020-05-26T15:59:49.473000-07:00",
        "ProvisionedThroughput": {

        }
    }
}
```

For more information, see Updating a Table in the *Amazon DynamoDB Developer Guide*.

Example 2: To create a global secondary index

The following example adds a global secondary index to the `MusicCollection` table.

```
aws dynamodb update-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=AlbumTitle,AttributeType=S \
    --global-secondary-index-updates file://gsi-updates.json
```

Contents of `gsi-updates.json`:

```
[
    {
        "Create": {
            "IndexName": "AlbumTitle-index",
            "KeySchema": [
                {
```

```
                    "AttributeName": "AlbumTitle",
                    "KeyType": "HASH"
                }
            ],
            "ProvisionedThroughput": {
                "ReadCapacityUnits": 10,
                "WriteCapacityUnits": 10
            },
            "Projection": {
                "ProjectionType": "ALL"
            }
        }
    }
]
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "AlbumTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],

```

For more information, see Updating a Table in the *Amazon DynamoDB Developer Guide*.

Example 3: To enable DynamoDB Streams on a table

The following command enables DynamoDB Streams on the `MusicCollection` table.

```
aws dynamodb update-table \
    --table-name MusicCollection \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_IMAGE
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "AlbumTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",

Example 4: To enable server-side encryption

The following example enables server-side encryption on the `MusicCollection` table.

```
aws dynamodb update-table \
    --table-name MusicCollection \
    --sse-specification Enabled=true,SSEType=KMS
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "AlbumTitle",

PowerShell

Tools for PowerShell V4

Example 1: Updates the provisioned throughput for the given table.

```
Update-DDBTable -TableName "myTable" -ReadCapacity 10 -WriteCapacity 5
```

- For API details, see UpdateTable in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Updates the provisioned throughput for the given table.

```
Update-DDBTable -TableName "myTable" -ReadCapacity 10 -WriteCapacity 5
```

- For API details, see UpdateTable in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `UpdateTimeToLive` with an AWS SDK or CLI

The following code examples show how to use `UpdateTimeToLive`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Work with Streams and Time-to-Live

CLI

AWS CLI

To update Time to Live settings on a table

The following `update-time-to-live` example enables Time to Live on the specified table.

```
aws dynamodb update-time-to-live \
    --table-name MusicCollection \
    --time-to-live-specification Enabled=true,AttributeName=ttl
```

Output:

```
{
    "TimeToLiveSpecification": {
        "Enabled": true,
        "AttributeName": "ttl"
    }
}
```

For more information, see Time to Live in the *Amazon DynamoDB Developer Guide*.

- For API details, see UpdateTimeToLive in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

Enable TTL on an existing DynamoDB table using AWS SDK for Java 2.x.

```

JavaScript

SDK for JavaScript (v3)

Enable TTL on an existing DynamoDB table.

```
import { DynamoDBClient, UpdateTimeToLiveCommand } from "@aws-sdk/client-
dynamodb";

export const enableTTL = async (tableName, ttlAttribute, region = 'us-east-1') =>
 {

    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const params = {
        TableName: tableName,
        TimeToLiveSpecification: {
            Enabled: true,
            AttributeName: ttlAttribute
        }
    };

    try {
        const response = await client.send(new UpdateTimeToLiveCommand(params));
        if (response.$metadata.httpStatusCode === 200) {
            console.log(`TTL enabled successfully for table ${tableName}, using
 attribute name ${ttlAttribute}.`);
        } else {
            console.log(`Failed to enable TTL for table ${tableName}, response
 object: ${response}`);
        }
        return response;
    } catch (e) {
        console.error(`Error enabling TTL: ${e}`);
        throw e;
    }
};

// Example usage (commented out for testing)
// enableTTL('ExampleTable', 'exampleTtlAttribute');
```

Disable TTL on an existing DynamoDB table.

```
import { DynamoDBClient, UpdateTimeToLiveCommand } from "@aws-sdk/client-
dynamodb";

export const disableTTL = async (tableName, ttlAttribute, region = 'us-east-1')
 => {

    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const params = {
        TableName: tableName,
        TimeToLiveSpecification: {
            Enabled: false,
            AttributeName: ttlAttribute
        }
    };

    try {
        const response = await client.send(new UpdateTimeToLiveCommand(params));
        if (response.$metadata.httpStatusCode === 200) {
            console.log(`TTL disabled successfully for table ${tableName}, using
 attribute name ${ttlAttribute}.`);
        } else {
            console.log(`Failed to disable TTL for table ${tableName}, response
 object: ${response}`);

        print("Couldn't disable TTL in table %s. Here's why: %s" % (table_name,
 ex))
        raise
```

```
# your values
disable_ttl("your-table-name", "expireAt")
```

- For API details, see UpdateTimeToLive in *AWS SDK for Python (Boto3) API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Scenarios for DynamoDB using AWS SDKs

The following code examples show you how to implement common scenarios in DynamoDB with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within DynamoDB or combined with other AWS services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- Accelerate DynamoDB reads with DAX using an AWS SDK
- Work with advanced DynamoDB Global Secondary Index scenarios using AWS Command Line Interface v2
- Build an application to submit data to a DynamoDB table
- Compare multiple values with a single attribute in DynamoDB with an AWS SDK
- Conditionally update a DynamoDB item with a TTL using an AWS SDK
- Connect to a local DynamoDB instance using an AWS SDK
- Count expression operators in DynamoDB with an AWS SDK
- Create an API Gateway REST API to track COVID-19 data
- Create a messenger application with Step Functions
- Create a photo asset management application that lets users manage photos using labels
- Create a DynamoDB table with a Global Secondary Index using the AWS SDK
- Create a DynamoDB table with warm throughput setting using an AWS SDK

- Create a web application to track DynamoDB data
- Create a websocket chat application with API Gateway
- Create a DynamoDB item with a TTL using an AWS SDK
- Create and manage DynamoDB global tables with Multi-Region Strong Consistency using an AWS SDK
- Create and manage DynamoDB global tables demonstrating MREC using an AWS SDK
- Delete DynamoDB data using PartiQL DELETE statements with an AWS SDK
- Detect PPE in images with Amazon Rekognition using an AWS SDK
- Getting started with NoSQL databases
- Insert DynamoDB data using PartiQL INSERT statements with an AWS SDK
- Invoke a Lambda function from a browser
- Manage DynamoDB Global Secondary Indexes using AWS Command Line Interface v2
- Manage DynamoDB resource-based policies using AWS Command Line Interface v2
- Monitor performance of Amazon DynamoDB using an AWS SDK
- Perform advanced DynamoDB query operations using an AWS SDK
- Perform list operations in DynamoDB with an AWS SDK
- Perform map operations in DynamoDB with an AWS SDK
- Perform set operations in DynamoDB with an AWS SDK
- Query a DynamoDB table by using batches of PartiQL statements and an AWS SDK
- Query a DynamoDB table using PartiQL and an AWS SDK
- Query a DynamoDB table using a Global Secondary Index with an AWS SDK
- Query a DynamoDB table using a begins_with condition with an AWS SDK
- Query a DynamoDB table using a date range in the sort key with an AWS SDK
- Query a DynamoDB table with a complex filter expression with an AWS SDK
- Query a DynamoDB table with a dynamic filter expression with an AWS SDK
- Query a DynamoDB table with a filter expression and limit with an AWS SDK
- Query a DynamoDB table with nested attributes using an AWS SDK
- Query a DynamoDB table with pagination using an AWS SDK
- Query a DynamoDB table with strongly consistent reads using an AWS SDK
- Query DynamoDB data using PartiQL SELECT statements with an AWS SDK

- Query a DynamoDB table for TTL items using an AWS SDK
- Query DynamoDB tables using date and time patterns with an AWS SDK
- Save EXIF and other image information using an AWS SDK
- Set up Attribute-Based Access Control for DynamoDB using AWS Command Line Interface v2
- Understand update expression order in DynamoDB with an AWS SDK
- Update a DynamoDB table setting with warm throughput using an AWS SDK
- Update a DynamoDB item with a TTL using an AWS SDK
- Update DynamoDB data using PartiQL UPDATE statements with an AWS SDK
- Use API Gateway to invoke a Lambda function
- Use Step Functions to invoke Lambda functions
- Use a document model for DynamoDB using an AWS SDK
- Use a high-level object persistence model for DynamoDB using an AWS SDK
- Use atomic counter operations in DynamoDB with an AWS SDK
- Use conditional operations in DynamoDB with an AWS SDK
- Use expression attribute names in DynamoDB with an AWS SDK
- Use scheduled events to invoke a Lambda function
- Work with DynamoDB Local Secondary Indexes using AWS Command Line Interface v2
- Work with DynamoDB Streams and Time-to-Live using AWS Command Line Interface v2
- Work with DynamoDB global tables and multi-Region replication with eventual consistency (MREC) using AWS Command Line Interface v2
- Work with DynamoDB resource tagging using AWS Command Line Interface v2
- Work with DynamoDB table encryption using AWS Command Line Interface v2

Accelerate DynamoDB reads with DAX using an AWS SDK

The following code example shows how to:

- Create and write data to a table with both the DAX and SDK clients.
- Get, query, and scan the table with both clients and compare their performance.

For more information, see Developing with the DynamoDB Accelerator Client.

Python

SDK for Python (Boto3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create a table with either the DAX or Boto3 client.

```
import boto3

def create_dax_table(dyn_resource=None):
    """
    Creates a DynamoDB table.

    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The newly created table.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table_name = "TryDaxTable"
    params = {
        "TableName": table_name,
        "KeySchema": [
            {"AttributeName": "partition_key", "KeyType": "HASH"},
            {"AttributeName": "sort_key", "KeyType": "RANGE"},
        ],
        "AttributeDefinitions": [
            {"AttributeName": "partition_key", "AttributeType": "N"},
            {"AttributeName": "sort_key", "AttributeType": "N"},
        ],
        "BillingMode": "PAY_PER_REQUEST",
    }
    table = dyn_resource.create_table(**params)
    print(f"Creating {table_name}...")
    table.wait_until_exists()
    return table
```

```
if __name__ == "__main__":
    dax_table = create_dax_table()
    print(f"Created table.")
```

Write test data to the table.

```
import boto3

def write_data_to_dax_table(key_count, item_size, dyn_resource=None):
    """
    Writes test data to the demonstration table.

    :param key_count: The number of partition and sort keys to use to populate
 the
                      table. The total number of items is key_count * key_count.
    :param item_size: The size of non-key data for each test item.
    :param dyn_resource: Either a Boto3 or DAX resource.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    some_data = "X" * item_size

    for partition_key in range(1, key_count + 1):
        for sort_key in range(1, key_count + 1):
            table.put_item(
                Item={
                    "partition_key": partition_key,
                    "sort_key": sort_key,
                    "some_data": some_data,
                }
            )
            print(f"Put item ({partition_key}, {sort_key}) succeeded.")

if __name__ == "__main__":
    write_key_count = 10
    write_item_size = 1000
    print(
```

```
        f"Writing {write_key_count*write_key_count} items to the table. "
        f"Each item is {write_item_size} characters."
    )
    write_data_to_dax_table(write_key_count, write_item_size)
```

Get items for a number of iterations for both the DAX client and the Boto3 client and report the time spent for each.

```
import argparse
import sys
import time
import amazondax
import boto3

def get_item_test(key_count, iterations, dyn_resource=None):
    """
    Gets items from the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param key_count: The number of items to get from the table in each
 iteration.
    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.
    """

Work with advanced DynamoDB Global Secondary Index scenarios using AWS Command Line Interface v2

The following code example shows how to work with advanced Global Secondary Index configurations.

- Create a table with multiple GSIs.
- Create a table with on-demand capacity and GSI.
- Put items into a table with multiple GSIs.
- Query multiple GSIs with different conditions.

Bash

AWS CLI with Bash script

Create a table with multiple GSIs.

```
# Create a table with multiple GSIs
aws dynamodb create-table \
    --table-name MusicLibrary \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
        AttributeName=AlbumTitle,AttributeType=S \
        AttributeName=Genre,AttributeType=S \
        AttributeName=Year,AttributeType=N \
    --key-schema \
```

```
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST \
    --global-secondary-indexes \
        "[
            {
                \"IndexName\": \"AlbumIndex\",
                \"KeySchema\": [{\"AttributeName\":\"AlbumTitle\",\"KeyType\":
\"HASH\"}],
                \"Projection\": {\"ProjectionType\":\"ALL\"}
            },
            {
                \"IndexName\": \"GenreYearIndex\",
                \"KeySchema\": [
                    {\"AttributeName\":\"Genre\",\"KeyType\":\"HASH\"},
                    {\"AttributeName\":\"Year\",\"KeyType\":\"RANGE\"}
                ],
                \"Projection\": {\"ProjectionType\":\"INCLUDE\",
\"NonKeyAttributes\":[\"Artist\",\"SongTitle\"]}
            }
        ]"
```

Create a table with on-demand capacity and GSI.

```
# Create a table with on-demand capacity and GSI
aws dynamodb create-table \
    --table-name MusicOnDemand \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
        AttributeName=Genre,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST \
    --global-secondary-indexes \
        "[
            {
                \"IndexName\": \"GenreIndex\",
                \"KeySchema\": [{\"AttributeName\":\"Genre\",\"KeyType\":\"HASH
\"}],
                \"Projection\": {\"ProjectionType\":\"ALL\"}
```

```
            }
        ]"
```

Put items into a table with multiple GSIs.

```
# Add items to MusicLibrary table
aws dynamodb put-item \
    --table-name MusicLibrary \
    --item '{
        "Artist": {"S": "The Beatles"},
        "SongTitle": {"S": "Hey Jude"},
        "AlbumTitle": {"S": "Past Masters"},
        "Genre": {"S": "Rock"},
        "Year": {"N": "1968"}
    }'

aws dynamodb put-item \
    --table-name MusicLibrary \
    --item '{
        "Artist": {"S": "Miles Davis"},
        "SongTitle": {"S": "So What"},
        "AlbumTitle": {"S": "Kind of Blue"},
        "Genre": {"S": "Jazz"},
        "Year": {"N": "1959"}
    }'
```

Query items from a table with multiple GSIs.

```
# Query the AlbumIndex GSI
echo "Querying AlbumIndex GSI:"
aws dynamodb query \
    --table-name MusicLibrary \
    --index-name AlbumIndex \
    --key-condition-expression "AlbumTitle = :album" \
    --expression-attribute-values '{":album":{"S":"Kind of Blue"}}'

# Query the GenreYearIndex GSI with a range condition
echo "Querying GenreYearIndex GSI with range condition:"
aws dynamodb query \
    --table-name MusicLibrary \
    --index-name GenreYearIndex \
```

```
    --key-condition-expression "Genre = :genre AND #yr > :year" \
    --expression-attribute-names '{"#yr": "Year"}' \
    --expression-attribute-values '{":genre":{"S":"Rock"},":year":{"N":"1965"}}'
```

Build an application to submit data to a DynamoDB table

The following code examples show how to build an application that submits data to an Amazon DynamoDB table and notifies you when a user updates the table.

Java

SDK for Java 2.x

Shows how to create a dynamic web application that submits data using the Amazon DynamoDB Java API and sends a text message using the Amazon Simple Notification Service Java API.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

This example shows how to build an app that enables users to submit data to an Amazon DynamoDB table, and send a text message to the administrator using Amazon Simple Notification Service (Amazon SNS).

For complete source code and instructions on how to set up and run, see the full example on GitHub.

This example is also available in the AWS SDK for JavaScript v3 developer guide.

Services used in this example

- DynamoDB
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Compare multiple values with a single attribute in DynamoDB with an AWS SDK

The following code examples show how to compare multiple values with a single attribute in DynamoDB.

- Use the IN operator to compare multiple values with a single attribute.
- Compare the IN operator with multiple OR conditions.
- Understand the performance and expression complexity benefits of using IN.

Java

SDK for Java 2.x

Compare multiple values with a single attribute in DynamoDB using AWS SDK for Java 2.x.

Python

SDK for Python (Boto3)

Compare multiple values with a single attribute using AWS SDK for Python (Boto3).

```
import boto3
from boto3.dynamodb.conditions import Attr, Key
from typing import Any, Dict, List, Optional

def compare_multiple_values(
    table_name: str,
    attribute_name: str,
    values_list: List[Any],
    partition_key_name: Optional[str] = None,
    partition_key_value: Optional[str] = None,
) -> Dict[str, Any]:
    """
    Query or scan a DynamoDB table to find items where an attribute matches any
 value from a list.

    This function demonstrates the use of the IN operator to compare a single
 attribute
    against multiple possible values, which is more efficient than using multiple
 OR conditions.

    Args:
        table_name (str): The name of the DynamoDB table.
        attribute_name (str): The name of the attribute to compare against the
 values list.
        values_list (List[Any]): List of values to compare the attribute against.
        partition_key_name (Optional[str]): The name of the partition key
 attribute for query operations.
        partition_key_value (Optional[str]): The value of the partition key to
 query.

    Returns:
        Dict[str, Any]: The response from DynamoDB containing the matching items.
    """
    # Initialize the DynamoDB resource
    dynamodb = boto3.resource("dynamodb")
    table = dynamodb.Table(table_name)

    # Create the filter expression using the is_in method
    filter_expression = Attr(attribute_name).is_in(values_list)

    # If partition key is provided, perform a query operation
    if partition_key_name and partition_key_value:
```

```
        key_condition = Key(partition_key_name).eq(partition_key_value)
        response = table.query(
            KeyConditionExpression=key_condition,
 FilterExpression=filter_expression
        )
    else:
        # Otherwise, perform a scan operation
        response = table.scan(FilterExpression=filter_expression)

    # Handle pagination if there are more results
    items = response.get("Items", [])
    while "LastEvaluatedKey" in response:

JavaScript

SDK for JavaScript (v3)

Update TTL on on an existing DynamoDB Item in a table, with a condition.

```
import { DynamoDBClient, UpdateItemCommand } from "@aws-sdk/client-dynamodb";
```

```
import { marshall, unmarshall } from "@aws-sdk/util-dynamodb";

export const updateItemConditional = async (tableName, partitionKey, sortKey,
 region = 'us-east-1', newAttribute = 'default-value') => {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const currentTime = Math.floor(Date.now() / 1000);

    const params = {
        TableName: tableName,
        Key: marshall({
            artist: partitionKey,
            album: sortKey
        }),
        UpdateExpression: "SET newAttribute = :newAttribute",
        ConditionExpression: "expireAt > :expiration",
        ExpressionAttributeValues: marshall({
            ':newAttribute': newAttribute,
            ':expiration': currentTime
        }),
        ReturnValues: "ALL_NEW"
    };

    try {
        const response = await client.send(new UpdateItemCommand(params));
        const responseData = unmarshall(response.Attributes);
        console.log("Item updated successfully: ", responseData);
        return responseData;
    } catch (error) {
        if (error.name === "ConditionalCheckFailedException") {
            console.log("Condition check failed: Item's 'expireAt' is expired.");
        } else {
            console.error("Error updating item: ", error);
        }
        throw error;
    }
};

// Example usage (commented out for testing)
// updateItemConditional('your-table-name', 'your-partition-key-value', 'your-
sort-key-value');
```

- For API details, see UpdateItem in *AWS SDK for JavaScript API Reference*.

Python

SDK for Python (Boto3)

Update TTL on on an existing DynamoDB Item in a table, with a condition.

```
from datetime import datetime, timedelta

import boto3
from botocore.exceptions import ClientError

def update_dynamodb_item_ttl(table_name, region, primary_key, sort_key,
 ttl_attribute):

Create an API Gateway REST API to track COVID-19 data

The following code example shows how to create a REST API that simulates a system to track daily cases of COVID-19 in the United States, using fictional data.

Python

SDK for Python (Boto3)

Shows how to use AWS Chalice with the AWS SDK for Python (Boto3) to create a serverless REST API that uses Amazon API Gateway, AWS Lambda, and Amazon DynamoDB. The REST API simulates a system that tracks daily cases of COVID-19 in the United States, using fictional data. Learn how to:

- Use AWS Chalice to define routes in Lambda functions that are called to handle REST requests that come through API Gateway.
- Use Lambda functions to retrieve and store data in a DynamoDB table to serve REST requests.
- Define table structure and security role resources in an AWS CloudFormation template.
- Use AWS Chalice and CloudFormation to package and deploy all necessary resources.
- Use CloudFormation to clean up all created resources.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- CloudFormation
- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Create a messenger application with Step Functions

The following code example shows how to create an AWS Step Functions messenger application that retrieves message records from a database table.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with AWS Step Functions to create a messenger application that retrieves message records from an Amazon DynamoDB table and sends them with Amazon Simple Queue Service (Amazon SQS). The state machine integrates with an AWS Lambda function to scan the database for unsent messages.

- Create a state machine that retrieves and updates message records from an Amazon DynamoDB table.
- Update the state machine definition to also send messages to Amazon Simple Queue Service (Amazon SQS).
- Start and stop state machine runs.
- Connect to Lambda, DynamoDB, and Amazon SQS from a state machine by using service integrations.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda
- Amazon SQS
- Step Functions

Create a photo asset management application that lets users manage photos using labels

The following code examples show how to create a serverless application that lets users manage photos using labels.

.NET

SDK for .NET

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

C++

SDK for C++

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition

- Amazon S3
- Amazon SNS

Java

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway

- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Kotlin

SDK for Kotlin

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

PHP

SDK for PHP

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Rust

SDK for Rust

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Create a DynamoDB table with a Global Secondary Index using the AWS SDK

The following code example shows how to create a table with global secondary index.

Java

SDK for Java 2.x

Create DynamoDB table with Global Secondary Index using AWS SDK for Java 2.x.

    }
```

- For API details, see CreateTable in *AWS SDK for Java 2.x API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Create a DynamoDB table with warm throughput setting using an AWS SDK

The following code examples show how to create a table with warm throughput enabled.

Java

SDK for Java 2.x

Create DynamoDB table with warm throughput setting using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeDefinition;
import software.amazon.awssdk.services.dynamodb.model.CreateTableRequest;
import software.amazon.awssdk.services.dynamodb.model.CreateTableResponse;
import software.amazon.awssdk.services.dynamodb.model.GlobalSecondaryIndex;
import software.amazon.awssdk.services.dynamodb.model.KeySchemaElement;
import software.amazon.awssdk.services.dynamodb.model.KeyType;
import software.amazon.awssdk.services.dynamodb.model.Projection;
import software.amazon.awssdk.services.dynamodb.model.ProvisionedThroughput;
import software.amazon.awssdk.services.dynamodb.model.ScalarAttributeType;
import software.amazon.awssdk.services.dynamodb.model.WarmThroughput;

    public static WarmThroughput buildWarmThroughput(final Long
 readUnitsPerSecond, final Long writeUnitsPerSecond) {
        return WarmThroughput.builder()
            .readUnitsPerSecond(readUnitsPerSecond)
            .writeUnitsPerSecond(writeUnitsPerSecond)
            .build();
    }

    /**
     * Builds a ProvisionedThroughput object with the specified read and write
 capacity units.
     *
     * @param readCapacityUnits The read capacity units
     * @param writeCapacityUnits The write capacity units
     * @return A configured ProvisionedThroughput object
     */
```

```
    public static ProvisionedThroughput buildProvisionedThroughput(
        final Long readCapacityUnits, final Long writeCapacityUnits) {
        return ProvisionedThroughput.builder()
            .readCapacityUnits(readCapacityUnits)
            .writeCapacityUnits(writeCapacityUnits)
            .build();
    }

    /**
     * Builds an AttributeDefinition with the specified name and type.
     *
     * @param attributeName The attribute name
     * @param scalarAttributeType The attribute type

Create a web application to track DynamoDB data

The following code examples show how to create a web application that tracks work items in an Amazon DynamoDB table and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

SDK for .NET

Shows how to use the Amazon DynamoDB .NET API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Amazon SES

Java

SDK for Java 2.x

Shows how to use the Amazon DynamoDB API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to use the Amazon DynamoDB API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in Amazon DynamoDB and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in a DynamoDB table.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example in the AWS Code Examples Repository on GitHub.

Services used in this example

- DynamoDB
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Create a websocket chat application with API Gateway

The following code example shows how to create a chat application that is served by a websocket API built on Amazon API Gateway.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with Amazon API Gateway V2 to create a websocket API that integrates with AWS Lambda and Amazon DynamoDB.

- Create a websocket API served by API Gateway.
- Define a Lambda handler that stores connections in DynamoDB and posts messages to other chat participants.
- Connect to the websocket chat application and send messages with the Websockets package.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Create a DynamoDB item with a TTL using an AWS SDK

The following code examples show how to create an item with TTL.

Java

SDK for Java 2.x

```
package com.amazon.samplelib.ttl;

import com.amazon.samplelib.CodeSampleUtils;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;

JavaScript

SDK for JavaScript (v3)

```
import { DynamoDBClient, PutItemCommand } from "@aws-sdk/client-dynamodb";

export function createDynamoDBItem(table_name, region, partition_key, sort_key) {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    // Get the current time in epoch second format
    const current_time = Math.floor(new Date().getTime() / 1000);

    // Calculate the expireAt time (90 days from now) in epoch second format
```

```
    const expire_at = Math.floor((new Date().getTime() + 90 * 24 * 60 * 60 *
 1000) / 1000);

    // Create DynamoDB item
    const item = {
        'partitionKey': {'S': partition_key},
        'sortKey': {'S': sort_key},
        'createdAt': {'N': current_time.toString()},
        'expireAt': {'N': expire_at.toString()}
    };

    const putItemCommand = new PutItemCommand({
        TableName: table_name,
        Item: item,
        ProvisionedThroughput: {
            ReadCapacityUnits: 1,
            WriteCapacityUnits: 1,
        },
    });

    client.send(putItemCommand, function(err, data) {
        if (err) {
            console.log("Exception encountered when creating item %s, here's what
 happened: ", data, err);
            throw err;
        } else {
            console.log("Item created successfully: %s.", data);
            return data;
        }
    });
}

// Example usage (commented out for testing)
// createDynamoDBItem('your-table-name', 'us-east-1', 'your-partition-key-value',
 'your-sort-key-value');
```

- For API details, see PutItem in *AWS SDK for JavaScript API Reference*.

Python

SDK for Python (Boto3)

```
from datetime import datetime, timedelta
```

```
import boto3

def create_dynamodb_item(table_name, region, primary_key, sort_key):
    """
    Creates a DynamoDB item with an attached expiry attribute.

    :param table_name: Table name for the boto3 resource to target when creating
 an item
    :param region: string representing the AWS region. Example: `us-east-1`
    :param primary_key: one attribute known as the partition key.
    :param sort_key: Also known as a range attribute.
    :return: Void (nothing)
    """
    try:
        dynamodb = boto3.resource("dynamodb", region_name=region)
        table = dynamodb.Table(table_name)

        # Get the current time in epoch second format
        current_time = int(datetime.now().timestamp())

        # Calculate the expiration time (90 days from now) in epoch second format
        expiration_time = int((datetime.now() + timedelta(days=90)).timestamp())

        item = {
            "primaryKey": primary_key,
            "sortKey": sort_key,
            "creationDate": current_time,
            "expireAt": expiration_time,
        }
        response = table.put_item(Item=item)

        print("Item created successfully.")
        return response
    except Exception as e:
        print(f"Error creating item: {e}")
        raise e

# Use your own values
create_dynamodb_item(
    "your-table-name", "us-west-2", "your-partition-key-value", "your-sort-key-
value"
```

```
)
```

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Create and manage DynamoDB global tables with Multi-Region Strong Consistency using an AWS SDK

The following code examples show how to create and manage DynamoDB global tables with Multi-Region Strong Consistency (MRSC).

- Create a table with Multi-Region Strong Consistency.
- Verify MRSC configuration and replica status.
- Test strong consistency across Regions with immediate reads.
- Perform conditional writes with MRSC guarantees.
- Clean up MRSC global table resources.

Bash

AWS CLI with Bash script

Create a table with Multi-Region Strong Consistency.

```
# Step 1: Create a new table in us-east-2 (primary region for MRSC)
# Note: Table must be empty when enabling MRSC
aws dynamodb create-table \
    --table-name MusicTable \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST \
```

```
    --region us-east-2

# Wait for table to become active
aws dynamodb wait table-exists --table-name MusicTable --region us-east-2

# Step 2: Add replica and witness with Multi-Region Strong Consistency
# MRSC requires exactly three replicas in supported regions
aws dynamodb update-table \
    --table-name MusicTable \
    --replica-updates '[{"Create": {"RegionName": "us-east-1"}}]' \
    --global-table-witness-updates '[{"Create": {"RegionName": "us-west-2"}}]' \
    --multi-region-consistency STRONG \
    --region us-east-2
```

Verify MRSC configuration and replica status.

```
# Verify the global table configuration and MRSC setting
aws dynamodb describe-table \
    --table-name MusicTable \
    --region us-east-2 \
    --query 'Table.
{TableName:TableName,TableStatus:TableStatus,MultiRegionConsistency:MultiRegionConsistenc
{Region:RegionName,Status:ReplicaStatus}}'
```

Test strong consistency with immediate reads across Regions.

```
# Write an item to the primary region
aws dynamodb put-item \
    --table-name MusicTable \
    --item '{"Artist": {"S":"The Beatles"},"SongTitle": {"S":"Hey Jude"},"Album":
 {"S":"The Beatles 1967-1970"},"Year": {"N":"1968"}}' \
    --region us-east-2

# Read the item from replica region to verify strong consistency (cannot read or
 write to witness)
# No wait time needed - MRSC provides immediate consistency
echo "Reading from us-east-1 (immediate consistency):"
aws dynamodb get-item \
    --table-name MusicTable \
    --key '{"Artist": {"S":"The Beatles"},"SongTitle": {"S":"Hey Jude"}}' \
    --consistent-read \
```

```
    --region us-east-1
```

Perform conditional writes with MRSC guarantees.

```
# Perform a conditional update from a different region
# This demonstrates that conditions work consistently across all regions
aws dynamodb update-item \
    --table-name MusicTable \
    --key '{"Artist": {"S":"The Beatles"},"SongTitle": {"S":"Hey Jude"}}' \
    --update-expression "SET #rating = :rating" \
    --condition-expression "attribute_exists(Artist)" \
    --expression-attribute-names '{"#rating": "Rating"}' \
    --expression-attribute-values '{":rating": {"N":"5"}}' \
    --region us-east-1
```

Clean up MRSC global table resources.

```
# Remove replica tables (must be done before deleting the primary table)
aws dynamodb update-table \
    --table-name MusicTable \
    --replica-updates '[{"Delete": {"RegionName": "us-east-1"}}]' \
    --global-table-witness-updates '[{"Delete": {"RegionName": "us-west-2"}}]' \
    --region us-east-2

# Wait for replicas to be deleted
echo "Waiting for replicas to be deleted..."
sleep 30

# Delete the primary table
aws dynamodb delete-table \
    --table-name MusicTable \
    --region us-east-2
```

- For API details, see the following topics in *AWS CLI Command Reference*.
  - CreateTable
  - DeleteTable
  - DescribeTable
  - GetItem

- PutItem
- UpdateItem
- UpdateTable

Java

SDK for Java 2.x

Create a regional table ready for MRSC conversion using AWS SDK for Java 2.x.

```
   public static CreateTableResponse createRegionalTable(final DynamoDbClient
dynamoDbClient, final String tableName) {

       if (dynamoDbClient == null) {
           throw new IllegalArgumentException("DynamoDB client cannot be null");
       }
       if (tableName == null || tableName.trim().isEmpty()) {
           throw new IllegalArgumentException("Table name cannot be null or
empty");
       }

       try {
           LOGGER.info("Creating regional table: " + tableName + " (must be
empty for MRSC)");

           CreateTableRequest createTableRequest = CreateTableRequest.builder()
               .tableName(tableName)
               .attributeDefinitions(
                   AttributeDefinition.builder()
                       .attributeName("Artist")
                       .attributeType(ScalarAttributeType.S)
                       .build(),
                   AttributeDefinition.builder()
                       .attributeName("SongTitle")
                       .attributeType(ScalarAttributeType.S)
                       .build())
               .keySchema(
                   KeySchemaElement.builder()
                       .attributeName("Artist")
                       .keyType(KeyType.HASH)
                       .build(),
                   KeySchemaElement.builder()
```

```
                        .attributeName("SongTitle")
                        .keyType(KeyType.RANGE)
                        .build())
                .billingMode(BillingMode.PAY_PER_REQUEST)
                .build();

            CreateTableResponse response =
dynamoDbClient.createTable(createTableRequest);
            LOGGER.info("Regional table creation initiated. Status: "
                + response.tableDescription().tableStatus());

            return response;

        } catch (DynamoDbException e) {
            LOGGER.severe("Failed to create regional table: " + tableName + " - "
+ e.getMessage());
            throw DynamoDbException.builder()
                .message("Failed to create regional table: " + tableName)
                .cause(e)
                .build();
        }
    }
```

Convert a regional table to MRSC with replicas and witness using AWS SDK for Java 2.x.

```
    public static UpdateTableResponse convertToMRSCWithWitness(
        final DynamoDbClient dynamoDbClient,
        final String tableName,
        final Region replicaRegion,
        final Region witnessRegion) {

        if (dynamoDbClient == null) {

Create and manage DynamoDB global tables demonstrating MREC using an AWS SDK

The following code example shows how to create and manage DynamoDB global tables with replicas across multiple Regions.

- Create a table with Global Secondary Index and DynamoDB Streams.
- Add replicas in different Regions to create a global table.
- Remove replicas from a global table.
- Add test items to verify replication across Regions.
- Describe global table configuration and replica status.

Java

SDK for Java 2.x

Create a table with Global Secondary Index and DynamoDB Streams using AWS SDK for Java 2.x.

```
   public static CreateTableResponse createTableWithGSI(
       final DynamoDbClient dynamoDbClient, final String tableName, final String
indexName) {

       if (dynamoDbClient == null) {
           throw new IllegalArgumentException("DynamoDB client cannot be null");
       }
       if (tableName == null || tableName.trim().isEmpty()) {
           throw new IllegalArgumentException("Table name cannot be null or
empty");
       }
       if (indexName == null || indexName.trim().isEmpty()) {
           throw new IllegalArgumentException("Index name cannot be null or
empty");
       }

       try {
           LOGGER.info("Creating table: " + tableName + " with GSI: " +
indexName);

           CreateTableRequest createTableRequest = CreateTableRequest.builder()
```

```
                .tableName(tableName)
                .attributeDefinitions(
                    AttributeDefinition.builder()
                        .attributeName("Artist")
                        .attributeType(ScalarAttributeType.S)
                        .build(),
                    AttributeDefinition.builder()
                        .attributeName("SongTitle")
                        .attributeType(ScalarAttributeType.S)
                        .build())
                .keySchema(
                    KeySchemaElement.builder()
                        .attributeName("Artist")
                        .keyType(KeyType.HASH)
                        .build(),
                    KeySchemaElement.builder()
                        .attributeName("SongTitle")
                        .keyType(KeyType.RANGE)
                        .build())
                .billingMode(BillingMode.PAY_PER_REQUEST)
                .globalSecondaryIndexes(GlobalSecondaryIndex.builder()
                    .indexName(indexName)
                    .keySchema(KeySchemaElement.builder()
                        .attributeName("SongTitle")
                        .keyType(KeyType.HASH)
                        .build())
                    .projection(

Projection.builder().projectionType(ProjectionType.ALL).build())
                    .build())

Detect PPE in images with Amazon Rekognition using an AWS SDK

The following code example shows how to build an app that uses Amazon Rekognition to detect Personal Protective Equipment (PPE) in images.

Java

SDK for Java 2.x

Shows how to create an AWS Lambda function that detects images with Personal Protective Equipment.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Getting started with NoSQL databases

The following code example shows how to:

- Create a table in DynamoDB
- Update data in a DynamoDB table
- Query data in a DynamoDB table
- Delete your DynamoDB table

Bash

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# DynamoDB Getting Started Tutorial Script
# This script demonstrates basic operations with Amazon DynamoDB:
# - Creating a table
# - Writing data to the table
# - Reading data from the table
# - Updating data in the table
# - Querying data in the table
# - Deleting the table (cleanup)

Insert DynamoDB data using PartiQL INSERT statements with an AWS SDK

The following code example shows how to insert data using PartiQL INSERT statements.

JavaScript

SDK for JavaScript (v3)

Insert items into a DynamoDB table using PartiQL INSERT statements with AWS SDK for JavaScript.

```
/**
 * This example demonstrates how to insert items into a DynamoDB table using
 PartiQL.
 * It shows different ways to insert documents with various index types.
 */
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import {
  DynamoDBDocumentClient,
  ExecuteStatementCommand,
  BatchExecuteStatementCommand,
} from "@aws-sdk/lib-dynamodb";

/**
 * Insert a single item into a DynamoDB table using PartiQL.
 *
 * @param tableName - The name of the DynamoDB table
 * @param item - The item to insert
 * @returns The response from the ExecuteStatementCommand
 */
export const insertItem = async (tableName: string, item: Record<string, any>) =>
 {
  const client = new DynamoDBClient({});
  const docClient = DynamoDBDocumentClient.from(client);

  // Convert the item to a string representation for PartiQL
  const itemString = JSON.stringify(item).replace(/"([^"]+)":/g, '$1:');

  const params = {
    Statement: `INSERT INTO "${tableName}" VALUE ${itemString}`,
  };

  try {
    const data = await docClient.send(new ExecuteStatementCommand(params));
    console.log("Item inserted successfully");
    return data;
  } catch (err) {
    console.error("Error inserting item:", err);
    throw err;
  }
};

/**
 * Insert multiple items into a DynamoDB table using PartiQL batch operation.
 * This is more efficient than inserting items one by one.
```

```
 *
 * @param tableName - The name of the DynamoDB table
 * @param items - Array of items to insert
 * @returns The response from the BatchExecuteStatementCommand
 */
export const batchInsertItems = async (tableName: string, items: Record<string,
 any>[]) => {
  const client = new DynamoDBClient({});
  const docClient = DynamoDBDocumentClient.from(client);

  // Create statements for each item
  const statements = items.map((item) => {
    const itemString = JSON.stringify(item).replace(/"([^"]+)":/g, '$1:');
    return {
      Statement: `INSERT INTO "${tableName}" VALUE ${itemString}`,
    };
  });

  const params = {
    Statements: statements,
  };

  try {
    const data = await docClient.send(new BatchExecuteStatementCommand(params));
    console.log("Items inserted successfully");
    return data;
  } catch (err) {
    console.error("Error batch inserting items:", err);
    throw err;
  }
};

/**
 * Insert an item with a condition to prevent overwriting existing items.
 * This is useful for ensuring you don't accidentally overwrite data.
 *
 * @param tableName - The name of the DynamoDB table
 * @param item - The item to insert
 * @param partitionKeyName - The name of the partition key attribute
 * @returns The response from the ExecuteStatementCommand
 */
export const insertItemWithCondition = async (
  tableName: string,
  item: Record<string, any>,
```

```
  partitionKeyName: string
) => {
  const client = new DynamoDBClient({});
  const docClient = DynamoDBDocumentClient.from(client);

  const itemString = JSON.stringify(item).replace(/"([^"]+)":/g, '$1:');
  const partitionKeyValue = JSON.stringify(item[partitionKeyName]);

  const params = {
    Statement: `INSERT INTO "${tableName}" VALUE ${itemString} WHERE
 attribute_not_exists(${partitionKeyName})`,
    Parameters: [{ S: partitionKeyValue }],
  };

  try {
    const data = await docClient.send(new ExecuteStatementCommand(params));
    console.log("Item inserted with condition successfully");
    return data;
  } catch (err) {
    console.error("Error inserting item with condition:", err);
    throw err;
  }
};

/**
 * Example usage showing how to insert items with different index types
 */
export const insertExamples = async () => {
  // Example table with a simple primary key (just partition key)
  const simpleKeyItem = {
    userId: "user123",
    name: "John Doe",
    email: "john@example.com",
  };
  await insertItem("UsersTable", simpleKeyItem);

  // Example table with composite key (partition key + sort key)
  const compositeKeyItem = {
    orderId: "order456",
    productId: "prod789",
    quantity: 2,
    price: 29.99,
  };
  await insertItem("OrdersTable", compositeKeyItem);
```

```
  // Example with Global Secondary Index (GSI)
  // The GSI might be on the email attribute
  const gsiItem = {
    userId: "user789",
    email: "jane@example.com",
    name: "Jane Smith",
    userType: "premium",  // This could be part of a GSI
  };
  await insertItem("UsersTable", gsiItem);

  // Example with Local Secondary Index (LSI)
  // LSI uses the same partition key but different sort key
  const lsiItem = {
    orderId: "order567",  // Partition key
    productId: "prod123", // Sort key for the table
    orderDate: "2023-11-15", // Potential sort key for an LSI
    quantity: 1,
    price: 19.99,
  };
  await insertItem("OrdersTable", lsiItem);

  // Batch insert example with multiple items
  const batchItems = [
    {
      userId: "user234",
      name: "Alice Johnson",
      email: "alice@example.com",
    },
    {
      userId: "user345",
      name: "Bob Williams",
      email: "bob@example.com",
    },
  ];
  await batchInsertItems("UsersTable", batchItems);
};
```

Invoke a Lambda function from a browser

The following code example shows how to invoke an AWS Lambda function from a browser.

JavaScript

SDK for JavaScript (v2)

You can create a browser-based application that uses an AWS Lambda function to update an Amazon DynamoDB table with user selections.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda

SDK for JavaScript (v3)

You can create a browser-based application that uses an AWS Lambda function to update an Amazon DynamoDB table with user selections. This app uses AWS SDK for JavaScript v3.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Manage DynamoDB Global Secondary Indexes using AWS Command Line Interface v2

The following code example shows how to manage the complete lifecycle of Global Secondary Indexes.

- Create a table with a Global Secondary Index.
- Add a new GSI to an existing table.
- Update (increase) GSI warm throughput.
- Query data using GSIs.
- Delete a GSI.

Bash

AWS CLI with Bash script

Create a table with a Global Secondary Index.

```
# Create a table with a GSI
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
        AttributeName=AlbumTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST \
    --global-secondary-indexes \
        "IndexName=AlbumIndex,\
        KeySchema=[{AttributeName=AlbumTitle,KeyType=HASH}],\
        Projection={ProjectionType=ALL}"
```

Add a new (on-demand) GSI to an existing table.

```
# Add a new GSI to an existing table
aws dynamodb update-table \
```

```
    --table-name MusicCollection \
    --attribute-definitions \
        AttributeName=Genre,AttributeType=S \
    --global-secondary-index-updates \
        "[{\"Create\":{\"IndexName\":\"GenreIndex\",\
        \"KeySchema\":[{\"AttributeName\":\"Genre\",\"KeyType\":\"HASH\"}],\
        \"Projection\":{\"ProjectionType\":\"ALL\"}}}]"
```

Update (increase) GSI warm throughput.

```
# Increase the warm throughput of a GSI (default values are 12k reads, 4k writes)
aws dynamodb update-table \
    --table-name MusicCollection \
    --global-secondary-index-updates \
        "[{\"Update\":{\"IndexName\":\"AlbumIndex\",\
        \"WarmThroughput\":{\"ReadUnitsPerSecond\":15000,\"WriteUnitsPerSecond
\":6000}}}]"
```

Query data using GSIs.

```
# Query the AlbumIndex GSI
aws dynamodb query \
    --table-name MusicCollection \
    --index-name AlbumIndex \
    --key-condition-expression "AlbumTitle = :album" \
    --expression-attribute-values '{":album":{"S":"Let It Be"}}'

# Query the GenreIndex GSI
aws dynamodb query \
    --table-name MusicCollection \
    --index-name GenreIndex \
    --key-condition-expression "Genre = :genre" \
    --expression-attribute-values '{":genre":{"S":"Jazz"}}'
```

Delete a GSI.

```
# Delete a GSI from a table
aws dynamodb update-table \
    --table-name MusicCollection \
```

```
    --global-secondary-index-updates \
        "[{\"Delete\":{\"IndexName\":\"GenreIndex\"}}]"
```

- For API details, see the following topics in *AWS CLI Command Reference*.
  - CreateTable
  - DeleteTable
  - Query
  - UpdateTable

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Manage DynamoDB resource-based policies using AWS Command Line Interface v2

The following code example shows how to manage the complete lifecycle of resource-based policies for DynamoDB tables.

- Create a table with a resource policy.
- Get a resource policy.
- Update a resource policy.
- Delete a resource policy.

Bash

AWS CLI with Bash script

Create a table with a resource policy.

```
# Step 1: Create a DynamoDB table
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
```

```
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST

# Step 2: Create a resource-based policy document
cat > policy.json << 'EOF'
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:role/DynamoDBReadOnly"
      },
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query",
        "dynamodb:Scan"
      ],
      "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection"
    }
  ]
}
EOF

# Step 3: Attach the resource-based policy to the table
aws dynamodb put-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection
 \
    --policy file://policy.json
```

Get a resource policy.

```
# Get the resource-based policy attached to a table
aws dynamodb get-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection
```

Update a resource policy.

```
# Step 1: Create an updated policy document
```

```
cat > updated-policy.json << 'EOF'
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::123456789012:role/DynamoDBReadOnly",
          "arn:aws:iam::123456789012:role/DynamoDBAnalytics"
        ]
      },
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query",
        "dynamodb:Scan"
      ],
      "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection"
    }
  ]
}
EOF

# Step 2: Update the resource-based policy on the table
aws dynamodb put-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection
 \
    --policy file://updated-policy.json
```

Delete a resource policy.

```
# Delete the resource-based policy from a table
aws dynamodb delete-resource-policy \
    --resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection
```

  - CreateTable
  - DeleteResourcePolicy
  - GetResourcePolicy

- PutResourcePolicy

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Monitor performance of Amazon DynamoDB using an AWS SDK

The following code example shows how to configure an application's use of DynamoDB to monitor performance.

Java

SDK for Java 2.x

This example shows how to configure a Java application to monitor the performance of DynamoDB. The application sends metric data to CloudWatch where you can monitor the performance.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch
- DynamoDB

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Perform advanced DynamoDB query operations using an AWS SDK

The following code examples show how to perform advanced query operations in DynamoDB.

- Query tables using various filtering and condition techniques.
- Implement pagination for large result sets.
- Use Global Secondary Indexes for alternate access patterns.
- Apply consistency controls based on application requirements.

Java

SDK for Java 2.x

Query with strongly consistent reads using AWS SDK for Java 2.x.

```

/**
 * Example usage:
 *
 * // Query all items in the "AWS DynamoDB" forum with pagination
 * const allItems = await queryWithPagination(
 *   { region: "us-west-2" },
 *   "ForumThreads",
 *   "ForumName",
 *   "AWS DynamoDB",
 *   25 // 25 items per page
 * );
 *
 * console.log(`Total items retrieved: ${allItems.length}`);
 *
 * // Notes on pagination:
 * // - LastEvaluatedKey contains the primary key of the last evaluated item
 * // - When LastEvaluatedKey is undefined/null, there are no more items to
 retrieve
 * // - ExclusiveStartKey tells DynamoDB where to start the next page
 * // - Pagination helps manage memory usage for large result sets
 * // - Each page requires a separate network request to DynamoDB
 */

Perform list operations in DynamoDB with an AWS SDK

The following code examples show how to perform list operations in DynamoDB.

- Add elements to a list attribute.
- Remove elements from a list attribute.
- Update specific elements in a list by index.
- Use list append and list index functions.

Java

SDK for Java 2.x

Demonstrate list operations using AWS SDK for Java 2.x.

```

    """
    Append values to a list, creating it if it doesn't exist.

    This function demonstrates how to safely append values to a list attribute,
    creating the list with default values if it doesn't exist.

    Args:
        table_name (str): The name of the DynamoDB table.
        key (Dict[str, Any]): The primary key of the item to update.
        list_name (str): The name of the list attribute.
        values_to_append (List[Any]): The values to append to the list.
        default_values (Optional[List[Any]]): The default values if the list
 doesn't exist.
            If not provided, values_to_append will be used as the default.

    Returns:
        Dict[str, Any]: The response from DynamoDB containing the updated
 attribute values.
    """

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Perform map operations in DynamoDB with an AWS SDK

The following code examples show how to perform map operations in DynamoDB.

- Add and update nested attributes in map structures.
- Remove specific fields from maps.
- Work with deeply nested map attributes.

Java

SDK for Java 2.x

Demonstrate map operations using AWS SDK for Java 2.x.

Perform set operations in DynamoDB with an AWS SDK

The following code examples show how to perform set operations in DynamoDB.

- Add elements to a set attribute.
- Remove elements from a set attribute.
- Use ADD and DELETE operations with sets.

Java

SDK for Java 2.x

Demonstrate set operations using AWS SDK for Java 2.x.

```

- For API details, see UpdateItem in *AWS SDK for Python (Boto3) API Reference*.

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Query a DynamoDB table by using batches of PartiQL statements and an AWS SDK

The following code examples show how to:

- Get a batch of items by running multiple SELECT statements.
- Add a batch of items by running multiple INSERT statements.
- Update a batch of items by running multiple UPDATE statements.
- Delete a batch of items by running multiple DELETE statements.

.NET

SDK for .NET

Go

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run a scenario that creates a table and runs batches of PartiQL queries.

```
import (
 "context"
 "fmt"
 "log"
 "strings"
 "time"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/dynamodb/actions"
)

// RunPartiQLBatchScenario shows you how to use the AWS SDK for Go
// to run batches of PartiQL statements to query a table that stores data about
 movies.
//
//   - Use batches of PartiQL statements to add, get, update, and delete data for
//     individual movies.
//
```

```
// This example creates an Amazon DynamoDB service client from the specified
 sdkConfig so that
// you can replace it with a mocked or stubbed config for unit testing.
//
// This example creates and deletes a DynamoDB table to use during the scenario.

Python

SDK for Python (Boto3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create a class that can run batches of PartiQL statements.

```
from datetime import datetime
from decimal import Decimal
import logging
from pprint import pprint

import boto3
from botocore.exceptions import ClientError

from scaffold import Scaffold

logger = logging.getLogger(__name__)

class PartiQLBatchWrapper:
    """
    Encapsulates a DynamoDB resource to run PartiQL statements.
    """

    def __init__(self, dyn_resource):
        """
        :param dyn_resource: A Boto3 DynamoDB resource.
```

```
        """
        self.dyn_resource = dyn_resource

    def run_partiql(self, statements, param_list):
        """
        Runs a PartiQL statement. A Boto3 resource is used even though
        `execute_statement` is called on the underlying `client` object because
the
        resource transforms input and output from plain old Python objects
(POPOs) to
        the DynamoDB format. If you create the client directly, you must do these
        transforms yourself.

        :param statements: The batch of PartiQL statements.
        :param param_list: The batch of PartiQL parameters that are associated
with
                           each statement. This list must be in the same order as
the
                           statements.
        :return: The responses returned from running the statements, if any.
        """

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Query a DynamoDB table using PartiQL and an AWS SDK

The following code examples show how to:

- Get an item by running a SELECT statement.
- Add an item by running an INSERT statement.
- Update an item by running an UPDATE statement.
- Delete an item by running a DELETE statement.

.NET

SDK for .NET

Go

SDK for Go V2

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run a scenario that creates a table and runs PartiQL queries.

```
import (
 "context"
 "fmt"
 "log"
 "strings"
 "time"

 "github.com/aws/aws-sdk-go-v2/aws"
 "github.com/aws/aws-sdk-go-v2/service/dynamodb"
 "github.com/awsdocs/aws-doc-sdk-examples/gov2/dynamodb/actions"
)

// RunPartiQLSingleScenario shows you how to use the AWS SDK for Go
// to use PartiQL to query a table that stores data about movies.
//
// * Use PartiQL statements to add, get, update, and delete data for individual
 movies.
//
// This example creates an Amazon DynamoDB service client from the specified
 sdkConfig so that
// you can replace it with a mocked or stubbed config for unit testing.
//
// This example creates and deletes a DynamoDB table to use during the scenario.
func RunPartiQLSingleScenario(ctx context.Context, sdkConfig aws.Config,
 tableName string) {
 defer func() {
  if r := recover(); r != nil {
   fmt.Printf("Something went wrong with the demo.")
  }
 }()
```

```
log.Println(strings.Repeat("-", 88))
log.Println("Welcome to the Amazon DynamoDB PartiQL single action demo.")

Create a class that can run PartiQL statements.

```
from datetime import datetime
from decimal import Decimal
import logging
from pprint import pprint

import boto3
from botocore.exceptions import ClientError

from scaffold import Scaffold

logger = logging.getLogger(__name__)

class PartiQLWrapper:
    """
    Encapsulates a DynamoDB resource to run PartiQL statements.
    """

    def __init__(self, dyn_resource):
        """
        :param dyn_resource: A Boto3 DynamoDB resource.
        """
        self.dyn_resource = dyn_resource
```

```
   def run_partiql(self, statement, params):
       """
       Runs a PartiQL statement. A Boto3 resource is used even though
       `execute_statement` is called on the underlying `client` object because
the
       resource transforms input and output from plain old Python objects
(POPOs) to
       the DynamoDB format. If you create the client directly, you must do these
       transforms yourself.

       :param statement: The PartiQL statement.
       :param params: The list of PartiQL parameters. These are applied to the
                      statement in the order they are listed.
       :return: The items returned from the statement, if any.
       """
       try:
           output = self.dyn_resource.meta.client.execute_statement(
               Statement=statement, Parameters=params
           )
       except ClientError as err:

Run a scenario that creates a table and runs PartiQL queries.

```
table_name = "doc-example-table-movies-partiql-#{rand(10**8)}"
scaffold = Scaffold.new(table_name)
sdk = DynamoDBPartiQLSingle.new(table_name)

new_step(1, 'Create a new DynamoDB table if none already exists.')
unless scaffold.exists?(table_name)
  puts("\nNo such table: #{table_name}. Creating it...")
  scaffold.create_table(table_name)
  print "Done!\n".green
end

new_step(2, 'Populate DynamoDB table with movie data.')
download_file = 'moviedata.json'
puts("Downloading movie database to #{download_file}...")
movie_data = scaffold.fetch_movie_data(download_file)
puts("Writing movie data from #{download_file} into your table...")
scaffold.write_batch(movie_data)
puts("Records added: #{movie_data.length}.")
print "Done!\n".green

new_step(3, 'Select a single item from the movies table.')
response = sdk.select_item_by_title('Star Wars')
puts("Items selected for title 'Star Wars': #{response.items.length}\n")
print response.items.first.to_s.yellow
print "\n\nDone!\n".green

new_step(4, 'Update a single item from the movies table.')
puts "Let's correct the rating on The Big Lebowski to 10.0."
sdk.update_rating_by_title('The Big Lebowski', 1998, 10.0)
print "\nDone!\n".green
```

```
  new_step(5, 'Delete a single item from the movies table.')
  puts "Let's delete The Silence of the Lambs because it's just too scary."
  sdk.delete_item_by_title('The Silence of the Lambs', 1991)
  print "\nDone!\n".green

  new_step(6, 'Insert a new item into the movies table.')
  puts "Let's create a less-scary movie called The Prancing of the Lambs."
  sdk.insert_item('The Prancing of the Lambs', 2005, 'A movie about happy
 livestock.', 5.0)
  print "\nDone!\n".green

  new_step(7, 'Delete the table.')
  return unless scaffold.exists?(table_name)

  scaffold.delete_table
end
```

Query a DynamoDB table using a Global Secondary Index with an AWS SDK

The following code examples show how to query a table using a Global Secondary Index.

- Query a DynamoDB table using its primary key.
- Query a Global Secondary Index (GSI) for alternate access patterns.
- Compare table queries and GSI queries.

Java

SDK for Java 2.x

Query a DynamoDB table using its primary key and a Global Secondary Index (GSI) with AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.QueryRequest;
import software.amazon.awssdk.services.dynamodb.model.QueryResponse;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;

import java.util.HashMap;
```

```
import java.util.Map;

   public QueryResponse queryTable(
       final String tableName, final String partitionKeyName, final String
 partitionKeyValue) {

       CodeSampleUtils.validateTableParameters(tableName, partitionKeyName,
 partitionKeyValue);

       // Create expression attribute names for the column names
       final Map<String, String> expressionAttributeNames = new HashMap<>();
       expressionAttributeNames.put(EXPRESSION_ATTRIBUTE_NAME_PK,
 partitionKeyName);

       // Create expression attribute values for the column values
       final Map<String, AttributeValue> expressionAttributeValues = new
 HashMap<>();
       expressionAttributeValues.put(
           EXPRESSION_ATTRIBUTE_VALUE_PK,
           AttributeValue.builder().s(partitionKeyValue).build());

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Query a DynamoDB table using a date range in the sort key with an AWS SDK

The following code examples show how to query a table using a date range in the sort key.

- Query items within a specific date range.
- Use comparison operators on date-formatted sort keys.

Java

SDK for Java 2.x

Query a DynamoDB table for items within a date range with AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.QueryRequest;
import software.amazon.awssdk.services.dynamodb.model.QueryResponse;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;

import java.time.LocalDate;
import java.util.HashMap;
import java.util.Map;
import java.util.logging.Level;
import java.util.logging.Logger;

    public QueryResponse queryWithDateRange(
        final String tableName,
        final String partitionKeyName,

Query a DynamoDB table with a complex filter expression with an AWS SDK

The following code examples show how to query a table with a complex filter expression.

- Apply complex filter expressions to query results.
- Combine multiple conditions using logical operators.
- Filter items based on non-key attributes.

Query a DynamoDB table with a dynamic filter expression with an AWS SDK

The following code examples show how to query a table with a dynamic filter expression.

- Build filter expressions dynamically at runtime.

- Construct filter conditions based on user input or application state.
- Add or remove filter criteria conditionally.

Java

SDK for Java 2.x

Query a DynamoDB table with a dynamically constructed filter expression using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.QueryRequest;
import software.amazon.awssdk.services.dynamodb.model.QueryResponse;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;

import java.util.HashMap;
import java.util.Map;

    public static QueryResponse queryWithDynamicFilter(
        final String tableName,
        final String partitionKeyName,
        final String partitionKeyValue,
        final Map<String, Object> filterCriteria,
        final Region region,
        final DynamoDbClient dynamoDbClient) {

        validateParameters(tableName, partitionKeyName, partitionKeyValue,
 filterCriteria);

        DynamoDbClient ddbClient = dynamoDbClient;
        boolean shouldClose = false;

        try {
            if (ddbClient == null) {
                ddbClient = createClient(region);
                shouldClose = true;
            }
```

```
            final QueryWithDynamicFilter queryHelper = new
QueryWithDynamicFilter(ddbClient);
            return queryHelper.queryWithDynamicFilter(tableName,
partitionKeyName, partitionKeyValue, filterCriteria);
        } catch (ResourceNotFoundException e) {
            System.err.println("Table not found: " + tableName);
            throw e;
        } catch (DynamoDbException e) {
            System.err.println("Failed to execute dynamic filter query: " +
e.getMessage());
            throw e;
        } catch (Exception e) {

Query a DynamoDB table with a filter expression and limit with an AWS SDK

The following code examples show how to query a table with a filter expression and limit.

- Apply filter expressions to query results with a limit on items evaluated.
- Understand how limit affects filtered query results.
- Control the maximum number of items processed in a query.

Query a DynamoDB table with pagination using an AWS SDK

The following code examples show how to query a table with pagination.

- Implement pagination for DynamoDB query results.
- Use the LastEvaluatedKey to retrieve subsequent pages.
- Control the number of items per page with the Limit parameter.

Java

SDK for Java 2.x

Query a DynamoDB table with pagination using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;

Query a DynamoDB table for TTL items using an AWS SDK

The following code examples show how to query for TTL items.

Java

SDK for Java 2.x

Query Filtered Expression to gather TTL items in a DynamoDB table using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.QueryRequest;
import software.amazon.awssdk.services.dynamodb.model.QueryResponse;
import software.amazon.awssdk.services.dynamodb.model.ResourceNotFoundException;

import java.util.Map;
import java.util.Optional;

        final QueryRequest request = QueryRequest.builder()
            .tableName(tableName)
            .keyConditionExpression(KEY_CONDITION_EXPRESSION)
            .filterExpression(FILTER_EXPRESSION)
            .expressionAttributeNames(expressionAttributeNames)
            .expressionAttributeValues(expressionAttributeValues)
            .build();

        try (DynamoDbClient ddb = dynamoDbClient != null
            ? dynamoDbClient
            : DynamoDbClient.builder().region(region).build()) {
            final QueryResponse response = ddb.query(request);
            System.out.println("Query successful. Found " + response.count() + "
 items that have not expired yet.");
```

```
            // Print each item
            response.items().forEach(item -> {
                System.out.println("Item: " + item);
            });

            return 0;
        } catch (ResourceNotFoundException e) {
            System.err.format(TABLE_NOT_FOUND_ERROR, tableName);
            throw e;
        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            throw e;
        }
```

- For API details, see Query in *AWS SDK for Java 2.x API Reference*.

JavaScript

SDK for JavaScript (v3)

Query Filtered Expression to gather TTL items in a DynamoDB table using AWS SDK for JavaScript.

```
import { DynamoDBClient, QueryCommand } from "@aws-sdk/client-dynamodb";
import { marshall, unmarshall } from "@aws-sdk/util-dynamodb";

export const queryFiltered = async (tableName, primaryKey, region = 'us-east-1')
 => {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const currentTime = Math.floor(Date.now() / 1000);

    const params = {
        TableName: tableName,
        KeyConditionExpression: "#pk = :pk",
        FilterExpression: "#ea > :ea",
        ExpressionAttributeNames: {
            "#pk": "primaryKey",
```

```
            "#ea": "expireAt"
        },
        ExpressionAttributeValues: marshall({
            ":pk": primaryKey,
            ":ea": currentTime
        })
    };

    try {
        const { Items } = await client.send(new QueryCommand(params));
        Items.forEach(item => {
            console.log(unmarshall(item))
        });
        return Items;
    } catch (err) {
        console.error(`Error querying items: ${err}`);
        throw err;
    }
}

// Example usage (commented out for testing)
// queryFiltered('your-table-name', 'your-partition-key-value');
```

- For API details, see Query in *AWS SDK for JavaScript API Reference*.

Python

SDK for Python (Boto3)

Query Filtered Expression to gather TTL items in a DynamoDB table using AWS SDK for Python (Boto3).

```
from datetime import datetime

import boto3

def query_dynamodb_items(table_name, partition_key):
    """

    :param table_name: Name of the DynamoDB table
    :param partition_key:
```

```
    :return:
    """
    try:
        # Initialize a DynamoDB resource
        dynamodb = boto3.resource("dynamodb", region_name="us-east-1")

        # Specify your table
        table = dynamodb.Table(table_name)

        # Get the current time in epoch format
        current_time = int(datetime.now().timestamp())

        # Perform the query operation with a filter expression to exclude expired
 items
        # response = table.query(
        #
 KeyConditionExpression=boto3.dynamodb.conditions.Key('partitionKey').eq(partition_key),
        #
 FilterExpression=boto3.dynamodb.conditions.Attr('expireAt').gt(current_time)
        # )
        response = table.query(

 KeyConditionExpression=dynamodb.conditions.Key("partitionKey").eq(partition_key),

 FilterExpression=dynamodb.conditions.Attr("expireAt").gt(current_time),
        )

        # Print the items that are not expired
        for item in response["Items"]:
            print(item)

    except Exception as e:
        print(f"Error querying items: {e}")

# Call the function with your values
query_dynamodb_items("Music", "your-partition-key-value")
```

- For API details, see Query in *AWS SDK for Python (Boto3) API Reference*.

Save EXIF and other image information using an AWS SDK

The following code example shows how to:

- Get EXIF information from a a JPG, JPEG, or PNG file.
- Upload the image file to an Amazon S3 bucket.
- Use Amazon Rekognition to identify the three top attributes (labels) in the file.
- Add the EXIF and label information to an Amazon DynamoDB table in the Region.

Rust

SDK for Rust

Get EXIF information from a JPG, JPEG, or PNG file, upload the image file to an Amazon S3 bucket, use Amazon Rekognition to identify the three top attributes (*labels* in Amazon Rekognition) in the file, and add the EXIF and label information to a Amazon DynamoDB table in the Region.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3

For a complete list of AWS SDK developer guides and code examples, see Using DynamoDB with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Set up Attribute-Based Access Control for DynamoDB using AWS Command Line Interface v2

The following code example shows how to implement Attribute-Based Access Control (ABAC) for DynamoDB.

- Create an IAM policy for ABAC.
- Create tables with tags for different departments.
- List and filter tables based on tags.

Bash

AWS CLI with Bash script

Create an IAM policy for ABAC.

```
# Step 1: Create a policy document for ABAC
cat > abac-policy.json << 'EOF'
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query",
        "dynamodb:Scan"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Department": "${aws:PrincipalTag/Department}"
        }
      }
    },
    {
```

```
      "Effect": "Allow",
      "Action": [
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb:DeleteItem",
        "dynamodb:BatchWriteItem"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Department": "${aws:PrincipalTag/Department}",
          "aws:ResourceTag/Environment": "Development"
        }
      }
    }
  ]
}
EOF

# Step 2: Create the IAM policy
aws iam create-policy \
    --policy-name DynamoDBDepartmentBasedAccess \
    --policy-document file://abac-policy.json
```

Create tables with tags for different departments.

```
# Create a DynamoDB table with tags for ABAC
aws dynamodb create-table \
    --table-name FinanceData \
    --attribute-definitions \
        AttributeName=RecordID,AttributeType=S \
    --key-schema \
        AttributeName=RecordID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --tags \
        Key=Department,Value=Finance \
        Key=Environment,Value=Development

# Create another table with different tags
aws dynamodb create-table \
    --table-name MarketingData \
    --attribute-definitions \
```

```
        AttributeName=RecordID,AttributeType=S \
    --key-schema \
        AttributeName=RecordID,KeyType=HASH \
    --billing-mode PAY_PER_REQUEST \
    --tags \
        Key=Department,Value=Marketing \
        Key=Environment,Value=Production
```

List and filter tables based on tags.

```
# List all DynamoDB tables
echo "Listing all tables:"
aws dynamodb list-tables

# Get ARNs for all tables
echo -e "\nGetting ARNs for all tables:"
TABLE_ARNS=$(aws dynamodb list-tables --query "TableNames[*]" --output text |
 xargs -I {} aws dynamodb describe-table --table-name {} --query "Table.TableArn"
 --output text)

# For each table ARN, list its tags
echo -e "\nListing tags for each table:"
for ARN in $TABLE_ARNS; do
    TABLE_NAME=$(echo $ARN | awk -F/ '{print $2}')
    echo -e "\nTags for table: $TABLE_NAME"
    aws dynamodb list-tags-of-resource --resource-arn $ARN
done

# Example: Find tables with a specific tag
echo -e "\nFinding tables with Environment=Production tag:"
for ARN in $TABLE_ARNS; do
    TABLE_NAME=$(echo $ARN | awk -F/ '{print $2}')
    TAGS=$(aws dynamodb list-tags-of-resource --resource-arn $ARN --query "Tags[?
Key=='Environment' && Value=='Production']" --output text)
    if [ ! -z "$TAGS" ]; then
        echo "Table with Production tag: $TABLE_NAME"
    fi
done
```

Understand update expression order in DynamoDB with an AWS SDK

The following code examples show how to understand update expression order.

- Learn how DynamoDB processes update expressions.
- Understand the order of operations in update expressions.
- Avoid unexpected results by understanding expression evaluation.

Java

SDK for Java 2.x

Demonstrate update expression order using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import software.amazon.awssdk.services.dynamodb.model.GetItemResponse;
import software.amazon.awssdk.services.dynamodb.model.ReturnValue;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemRequest;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemResponse;

import java.util.HashMap;
import java.util.Map;

    /**
     * Demonstrates the effect of update expression order.
     *
     * <p>This method shows how the order of operations in an update expression
     * affects the result of the update.
     *
     * @param dynamoDbClient The DynamoDB client
```

```
     * @param tableName The name of the DynamoDB table
     * @param key The key of the item to update
     * @return Map containing the results of different update orders
     * @throws DynamoDbException if an error occurs during the operation
     */
    public static Map<String, Object> demonstrateUpdateOrder(
        DynamoDbClient dynamoDbClient, String tableName, Map<String,
AttributeValue> key) {

        Map<String, Object> results = new HashMap<>();
